The Austrian campaign of 1809 shed considerable lustre on the already high military character of Masséna. He greatly distinguished himself at Landshut and Eckmühl. The rapid capture of the strategic castle of Klenau was memorable; from its position on the river Traun, was deemed almost impregnable, especially attracted the admiration of Napoleon. At the battle of Battle of Essling [Lannes, P. C. S.] the defence of the village of Aspern was confided to Masséna, and it is general}
Mason, who in engraving appears to have been self-taught, had extreme facility and certainty of execution, and he was one of the first artists who made a marked distinction in the textures of the objects which he engraved; he was also extremely successful in his mode of representing colour. The fantastic and fanciful manner in which he engraved his portraits, has been condemned by some critics as more brusque to display his own remarkable facility in handling the graver; in some heads the features are engraved in continuous and peculiar lines. He was very fond of playing his skill also in executing hair, whether of man or beast, though he frequently sacrificed truth to his propensity for making these fine lines, and in draperies and animals he has given it a flat, hard, and diverse effect. But this peculiarity is the most striking feature of some of his works. A print, after Titian, of the Disciples at Emmaus, is from the nature of the cloth on the table generally known as La Nappe, and there is a dog in the picture which is such a mass of hair, that upon a close inspection it appears, says Watelet, to be made entirely of straw; yet notwithstanding these peculiarities, says the same intelligent critic, this print is the best engraving after Titian. Watelet says that Mason's faults are faults which he would have, and that they are always compensated by his beauties. The print of the Disciples at Emmaus has an additional value beyond its merits as an engraving, for, with the exception of the praying bishop who is the Emperor Adrian IV, the other is the Emperor Charles V, the host is the emperor's confessor, and the attendant is Philip II. of Spain. Mason died at Paris, under the protection of the engravers in order to become a member of the French Academy of Printing. He has executed many portraits, several after his own paintings, and some of them are nearly of the size of life. Mason's portraits have a peculiar interest also as representing a group of the most distinguished men during the reign of Louis XIV. His historical pieces are not numerous, but they are all excellent.

MASON. [MASON, SHIP-BUILDER, P. C.]

MASTER AND SERVANT. [SERVANT, P. C.]

MASTER OF A SHIP. [SHIPS, P. C.]

MASTERS IN LUNACY. [LUNACY, P. C.]

MASON, ABU-l-HASAN 'ALI BEN-HUSEIN BEN-'ALI, one of the most celebrated Arabian writers, was born, according to his own statement, at Baghdir, in the 6th century of the hejira, or the 9th of the Christian era. He belonged to the illustrious family of 'Abdallah-ben-'Ali-ben-Mastin, and was amongst the few early followers of Mohammed who accompanied the prophet on his flight from Mecca to Medina. Mason's life was filled with great talents, which he applied at an early age to the pursuit of science, and which was written in a spirit of such bitter invective that it produced a sensible effect on his mind and health, already enfeebled by bodily infirmities, and is said to have hastened his death, which took place at Cairo on Monday, 18th April, 1617. At his death, he was pronounced by General Thibault, was inserted in the Mémoire, and afterwards published separately.

Mason was gifted by nature with a powerful frame of body and indomitable resolution. His bravery was rather characterised by perseverance than by impecuniosity. He was considered the most skilful tactician among Napoleon's generals, and on the field of battle he was remarkable for the coolness and precision of his aim and for his penetrating insight into the intended movements of the enemy. He had moreover the invaluable quality in a commander of not being deflected by grief. His faults and vices we have already alluded to; they were principally rapacity and avarice, and they frequently brought down upon him the displeasure and punishment of his chief.

[Alison, vol. iii. p. 431. Les Cosa, Mémoire de St. Héron, Courtois and Camp of Napoleon: Dict. Hist. de Battailles; Biographie Moderne; et al., Mémoire sur la Compagnie de 1809, Paris, 1823-26, 4 vols. (accurate military writer was also editor-camp to Masséna); Napier, Hist. of the Peninsular War.]

MASON, ANTOINE. This celebrated French engraver and painter was born at Loury, near Orleans, in 1656, and was originally an armurer and damasquinier, damaser, damasquinier, and an engraver in metal, and an artist in much request in the days of armour and chivalry.

Mason, who in engraving appears to have been self-taught, had extreme facility and certainty of execution, and he was one of the first artists who made a marked distinction in the textures of the objects which he engraved; he was also extremely successful in his mode of representing colour. The fantastical and fanciful manner in which he engraved his portraits, has been condemned by some critics as more brusque to display his own remarkable facility in handling the graver; in some heads the features are engraved in continuous and peculiar lines. He was very fond of playing his skill also in executing hair, whether of man or beast, though he frequently sacrificed truth to his propensity for making these fine lines, and in draperies and animals he has given it a flat, hard, and diverse effect. But this peculiarity is the most striking feature of some of his works. A print, after Titian, of the Disciples at Emmaus, is from the nature of the cloth on the table generally known as La Nappe, and there is a dog in the picture which is such a mass of hair, that upon a close inspection it appears, says Watelet, to be made entirely of straw; yet notwithstanding these peculiarities, says the same intelligent critic, this print is the best engraving after Titian. Watelet says that Mason's faults are faults which he would have, and that they are always compensated by his beauties. The print of the Disciples at Emmaus has an additional value beyond its merits as an engraving, for, with the exception of the praying bishop who is the Emperor Adrian IV, the other is the Emperor Charles V, the host is the emperor's confessor, and the attendant is Philip II. of Spain. Mason died at Paris, under the protection of the engravers in order to become a member of the French Academy of Printing. He has executed many portraits, several after his own paintings, and some of them are nearly of the size of life. Mason's portraits have a peculiar interest also as representing a group of the most distinguished men during the reign of Louis XIV. His historical pieces are not numerous, but they are all excellent.
Mohammedism, Christianity, those of Zoroaster and Confucius, and the idolatries of barbarous nations. His geographical knowledge was no less extensive and correct than his acquaintance with history, and no Arabian writer can boast like him of the title of 'hierotamitardus,' in the words of the historian. In the introduction to Dr. Spranger's translation of the 'Golden Meadows,' Mas'udi is thus compared with Herodotus—'If it is the warmth for his own nationality and tenets without prejudice against what is foreign; the elasticity of mind to receive impressions, and to appreciate opinions, without want of firmness and principles; the thirst for correctness of information without preconceived criticism, which rejects in toto what is false, if it differ from known facts; the vastness of experience and deep learning acquired through extensive journeys, frequent intercourse with men of all nations and opinions, without neglecting that self-knowledge which is acquired in solitary self-contemplation and the basis of history (?); and if it is that extensive knowledge and enlarged mind which embraces all past, reflecting on the present; and that sound criticism, which, entering into the feelings of nations, and penetrated by those ideas, imaginations, and tendencies which mankind feel at all times, select what is national and characteristic although it may not always bear the stamp of logical reasoning; if it is for these reasons that Herodotus is called the Father of History, and of the greatest of all historians—El-Mas'udi has a just claim to be called the Herodotus of the Arabs.'—A characteristic feature of Mas'udi is his want of method in arranging his historical material. The 'Golden Meadows' are never failed to supply him with what he was writing. He illustrates the history or geography of the West with anecdotes or contrasts taken from China or Arabia; he avails himself of his powerful imagination; he has the power of surprising his reader with the stories of different Mohammedan sects; and while he informs the reader of the mysteries of the extreme North, he will all at once forget his subject and transfer him into the desert of the Sahara. In this latter respect, the book bears a strong resemblance to Gibbon's 'Decline and Fall.'

G. Niebuhr, although this peculiaritiy of the German historian is less apparent in his works than it was in his lectures.

The principal works of Mas'udi are: 1, 'Abhīdīrz-e-zemā,' or 'The Book of Knowledges;' 2, 'Abhīdīrz-e-marā'z,' or 'The Book of Emotions;' 3, 'The Book of the Middle,' the word 'āfāst; the plural of 'wast,' being probably taken in the sense of 'proportionate,' 'not exceeding a certain size.' This is the complement to No. 1, and treats of the most curious and important questions in history and geography. There is no MS. of it in Europe, and we know some of its details only through the quotations of some Arabic writers. Aware that his works were too voluminous, Mas'udi wrote, 3, 'Mordj- dhelwel el-mudd-un-al-jelwih,' his celebrated 'Meadows of Gold and Mines of Gems.' This is an extract with additions from No. 1 and 2. In the Leyden MS. perused by Dr. Spranger, the work is divided into 132 chapters, of which the doctor gives the titles in the introduction to the first volume of his translation of the work; in a Paris MS. it is divided into 129 chapters, 65 of which treat on foreign countries, and the remainder on the Empire of the Arabs. Mas'udi wrote, 4, 'Abhīdīrz-e-ākīdāt,' according to the author, for each chapter bears the date when the author finished it. This seems, however, scarcely credible. In a.m. 545 the author issued a second edition consisting of 7 volumes; this edition was more consonant, and met with less favour from the public than the first edition, of which there are many MSS. in the East as well as in Europe; but there is no MS. extant of the second edition. A Spanish Arab, El Shekhit, a native of Xativa, made an extract from the 'Golden Meadows,' and so did Reiske during his residence at Leyden. The 'Historia

The translation of the whole work, of which the first volume, containing the first seven chapters, translated by Dr. Aloys Spranger, with the co-operation of the late Earl of Munster, appeared under the title 'El-Mas'udi's Historical Encyclopedia entitled Meadows of Gold and Mines of Gems,' 1st vol., London, 1841, 8vo. The 'Golden Meadows' treat on the history, geography, religion, manners, and politics of most of the Eastern and European nations, and are full of matter both important and curious.

The following are works of Mas'udi, some of which are extant in MS., but most of them are only known by being quoted by other writers:—

3, 'Kitāb fonūn-al-m-riffī', &c., 'Different Branches of Science,' and of what has happened in bygone times; 5, 'Kitāb dekhāir-al-olūm,' &c., 'Treasury of Science,' &c.; 6, 'Kitāb al-m-eisāfī, &c., 'The Book of Questions on the Causes of Religious Differences'; 10, 'Kitāb sun-al-hāyāh,' &c., 'The Physician of the Soul,' with a metaphysical digression on dreams; 13, 'Haddās al-dāsār,' &c., 'Flora,' contains historical information on the descendants of Mohammed and their virtues; 14, 'Al-māšīfī we al-tādīkhī,' &c., 'On Principles and Compositions,' treats among other subjects on the influence of the sun and the moon; 15, 'Kitāb as-ṣabīrī ahsān al-mūdārī, &c., 'The Book on the Seventy Chapters,' treats on the policy of kings, and is a very remarkable work.
M A T

MACHII, in Gunnery, is a material employed in firing military mines or in discharging pieces of ordnance. Before the invention of fire-locks, hand-guns or small-arms were fired of matchlocks, one kind of which is still more efficient; and match-lock fire-arms are still used in some parts of Asia.

What is called slow-match is only a piece of slightly twisted hemp which has been soaked in a strong solution of saltpetre. When it has been thoroughly wet, and, if necessary, rubbed to it, it burns very slowly, and a piece one yard long is scarcely consumed in eight hours. In use, the end to which fire has been applied is blown upon by the breath, when it is capable of setting fire to gunpowder or to the cotton-wool inserted in the percussion cap, which will ignite a fuse.

The materials employed in the formation of quick-match consist of a mixture of saltpetre and melted gunpowder with some woollen thread, in which the saltpetre is put, is made to boil for an hour in a copper vessel, a wick of cotton being coiled in the liquid; the alcohol is then added, and the mixture is allowed to simmer over a slow fire for a quarter of an hour. Some of the powder is afterwards introduced, and the whole is kept during twenty-four hours. The cotton is then wound on a reel and the remainder of the powder is sifted over it. The match is then left for several days in order that it may become thoroughly dry, after which it is fit for use.

MATHAM, JACOB, a celebrated Dutch engraver and painter, was born at Haarlem in 1671. He was the pupil of Govert Flinck, and Matham's art was greatly admired by whom he acquired considerable fortune. Matham's prints are very numerous; Bartch describes nearly 300. He died in 1681.

(Bartch, Pinxsier-Gravers."

MATIC — Medical Properties of. This name is applied to a straggling plant brought from Peru, where it has long enjoyed a high reputation for its styptic properties. Doubts exist as to the botanical origin of the plant, some writers state it to be a Latin plant, resembling the Philodendron, while others refer it to a piperaceous plant, and even assert that it is the piper sauvignoni, Ruiz et Pavon, a native not of Peru, but also of Cayenne, and the Caribbean islands. The colour of the leaves, somewhat resembling a mastic, and the large quantity of volatile oil obtained from them, lend countenance to the former opinion; while the alternate position of the leaves in most of the specimens described, entirely negatives this notion. The probability is, that two distinct plants pass under the name of Maticor, which, though they have a distinct origin, have similar properties. Frequent instances of this are found in Brazil, where numerous plants are called capoeira; and several, reputed antidotes to the bites of serpents, are all termed capoeira. The analysis of the leaves seems to have been made on the piperaceous plant, which is stated to yield a drink employed by the Indians to cause effects similar to those obtained from the Cannabis Indica. This fact strengthens the idea of its being a piper, since the piper methysticum yields a highly intoxicating beverage. Maticor has been analysed by Dr. Fitch; it contains: 1, a yellow, dark-green resin; 3, a brown colouring matter; 4, a yellow colouring matter; 5, gum, and nitrate of potash; 6, a bitter principle, Maticor; 7, an aromatic volatile oil; 8, ashes; 9, lignin.

Cold water extracts, in about four hours, all the medicinal virtues of the plant, and is an eligible means of administering it. A tincture is also employed, and the powdered leaves are given both internally and applied externally. It does not owe its straggling properties to tannin: and it seems to exert a vital action on bleeding vessels, so as speedily to arrest the hemorrhage. It has been used to check other discharges, such as the profuse expectation and also the night-sweats of consumptive patients. Few drugs exert more than a temporary influence over these symptoms; but among such, Maticor seems well entitled to attention.

MATICOR/AIA, a genus of plants belonging to the natural order Composite, the suborder Cynobifere, the tribe Seneceiideae, and the section Anthemiade. It has a nearly flat involucre with an elongated conical receptacle; the fruit is baccate; and the pappus is either absent, or in its place there is a slightly membranous border.

M. Caminomura, Wild Camomile, has bi-pinnae smooth leaves, capillary simple or divided segments, solitary heads of flowers; it grows on open hills throughout Europe, on damp-hills, in cultivated ground, and on waysides and waste places. It was formerly used as a medicine, but its place has been taken by the common Chamomile and other plants of the same order. It is the Atheneic of Dioscorides, lib. 3, cap. 144. The Pyrfreither Parthenium, Fever-fever, is by some botanists referred to Matricaria. This plant is of the genus Matricaria, which contains the celebrated "Hart Plant," lib. 14, cap. 7, and the Harveya of Dioscorides, lib. 3, cap. 135; and of Plutarch (Sallia, cap. 13). Other plants, as species of Pararicia, Chrysocoma, &c., were called gypsi-

(Bartch, Manual of British Botany; Fuss, Synopsis Flora Plant. Classica.)

MAURICE, THE REV. THOMAS, was born about 1754, at Ashtead, near Epsom, and was educated at the Christ's Hospital school. After his father's death the family was impoverished by an unfortunate marriage of the widow: and his education proceeded irregularly till Dr. Parr, one of his uncles, was induced to take him as a pupil, and treated him with great generosity and kindness. At the age of nineteen he was entered at St. John's College, Oxford, whence he removed next year to University College. After taking his degree of B.A., he was ordained by Bishop Lowth; and he held for some time the curacy of the large parish of Woodford in Essex, which in 1785 he resigned for a chapel at Epping, in order to obtain a water leisure for study. Next year he married: but his wife lived no more than four years. He had already published a translation of the Ceditius Tyrannus, and several other volumes of poems: and he continued to publish many other volumes of poetry. He was afterwards a professor of Greek at the University of Oxford, and was chancellor of University College by his distinguished tutor Lord Stowell; and before removing to Epping he had begun to concentrate his attention on the history of India, for dealing with which he had received a free grant of one hundred a year. He was one of the first to address the East India Directors. The irreligious spirit of the French revolution, alarming Mr. Maurice's mind, induced him to remodel his first work after it was nearly completed, and the result of the improvements of one of its dissertations on the Hindu mythology. His Indian Antiquities began to be published in 1791, when two volumes appeared, in octavo: the rest were brought out at intervals, the completion of the work being mainly the result of the administration of Earl of Harborough; and the seventh and last volume appeared in 1797. Meantime he had undertaken his History of Hindostan, the three volumes of which, in quarto, were published in 1795, 1798, 1799; and a second edition appeared in 1821. In 1798 Earl Spencer presented him to the vicarage of Wormleighton in Warwickshire: next year he was appointed assistant librarian in the British Museum: in 1800 Bishop Tomline obtained for him the pecuniary assistance held by the poet Cowper: and in 1804 he received from the Lord Chancellor the vicarage of Cadham in Kent. His Modern History of Hindostan, in two volumes, appeared in 1802 and 1804. His views of the history of the British East Indies and attempts in verse, succeeded this work: and one of his last undertakings was his History of the Progress of Indian Literature, and Anecdotes of those who have written in the East Indies, in 1810. Of this, the second edition appeared in 1821, 1820, and 1822. Mr. Maurice died at his apartments in the British Museum, on the 29th of March, 1824.

MAURICNAS, JUUSNUS, a Roman jurist, who appears to have been writing in the time of the emperor Antoninus Pius, from an expression which he uses (Dig. 33, tit. 2, s. 203); he was therefore a contemporary of Galen. The only work of his that is mentioned in the Florineum Index is six books Ad Leges. There are four excerpts from Maurinianus in the Digest.

MAURY, JEAN SIFFREIN, Cardinal, was born on the 29th June, 1746, at Vezins, in the Vexin, of poor but respectable parents. He showed at a very early age a great disposition for learning, and, being destined by his parents for the ecclesiastical profession, he was placed at the seminary of St. Germain, at Avignon, in pursuance of his theological studies. At the age of eighteen he proceeded to Paris, in the expectation of earning a subsistence by the cultivation of his talents. Though he was without friends in that city, his first publishing some considerable views, most encouraged by this early success he took orders, and devoted himself to the study of popish eloquence. In 1772 an "Éloge" on Fénélon, which he published, was favourably received by the French Academy; and the cardinal of Fleury, who was familiar with the works of his disciple, gave him a prebend at the Abbey of St. Denis. He however soon returned to Paris, where he became very popular as a preacher. A panegyrist of St. Louis, which he delivered before the French Academy, and one of St. Augustine
before an assembly of the clergy, met with so much success that the abbey of Framonde in the diocese of Saintes was bestowed upon him by the king, Louis XVI., who likewise appointed him preacher to the court. In 1786 he became a member of the Académie des Sciences, Letters, and Arts of the unfortunate Louis XVI., and continued a prominent part in the debates. From the first he enlisted himself on the aristocratic side, where his energetic eloquence and peculiar talent at reply rendered him a formidable antagonist to M. de Mirabeau. The oratory, which he expressed opinions hostile to the great majority of the assembly, was often listened to with admiration and greeted with applause. His great moral courage and firm adherence to the principles which he had adopted secured for him the respect and esteem of the more enlightened portion of his enemies. Opposed in debate by Mirabeau, Barnave, and Clermont-Tonnerre, he interposed at every step by the bises or cries of one or two thousand spectators in the galleries; certain of being defeated in all his efforts by an overwhelming majority; in danger of being stoned, strung up to the lamp-post, or torn to pieces at the close of every interesting debate, he still continued to speak, his voice was not deviated from his duty, but was ever to be found at his post. A true soldier of the church, he threw himself with undisguised valor into the breach, and it was hard to say whether he was the defender or the confessor of the king. The battle of declamation, the cutting force of his sarcasm, or the inexhaustible resources of his knowledge, were most conspicuous. (Allison, History of Europe, vol. i. p. 590.) On the 27th of November, 1787, he was appointed to the sees of Montfiascone, by which every ecclesiastical kingdom was required to take an oath to maintain all his power the new constitution; and in case of any priest's refusal, it was declared that he should be held to have renounced his benefits. To this constitution the pope had refused his sanction, on account of its hostility to the interests of the church, and the oath was indignantly refused by the majority of the clergy. When the day arrived for the taking it by the bishops and clergy of the Assembly, an infuriated mob surrounded the hall, threatening death to all who should refuse. On this occasion also Maury displayed his usual intrepidity, and boldly advocated the independence of his order. Strike, but hear me," was his explanation, when the last efforts of his impassioned eloquence in that Assembly were interrupted by the incessant cries of his political antagonists. At the close of the stormy session of the National Assembly, Maury, who could lend no further aid to the prostrate cause of royalty and religion, quitted his native country, and, at the invitation of M. de Mirabeau, went to Suaraworle, and he soon afterwards received with the highest distinction, and the loss of his beneficences in France was more than compensated by his speedy elevation to the highest situations in the Roman church. In 1789 he was consecrated Bishop of Châtillon, and afterwards appointed apostolical nuncio to the diet held at Frankfurt for the election of the emperor Francis II. This mission accomplished, in 1794 he was elevated to the dignity of a cardinal, and was instituted to the united sees of Montfiascone and Corneto.

On the invasion of Italy by the French in 1798, though every effort was made to seize Cardinal Maury, he escaped under disguise to Venice, where he assisted at the conventual election for Pope Pius VII. In 1799 he returned to Rome upon the conquest of Italy by Suaraworle, and was accredited as ambassador to his native city, Louis XVI. He was domiciled at Monte Maitre. This office he resigned on the reconciliation of the church of Rome with the government of the French in November, on which occasion he addressed to the First Consul better counsels than those of the party who had sided with so much personal hazard. Napoleon gladly received the proposal of a reconciliation with so distinguished a member of the church whose establishment he had been seeking in France; an interview was accordingly fixed between them at Grenoble, and in May, 1806, Maury reappeared at Paris. The flattering reception he there met with was calculated to attach him to the interests of this chief, who admitted him to his intimate circle, and himself of his counsels in ecclesiastical matters. He received the pension assigned to the dignity of a French cardinal, and was appointed First Almoner of Jerome Bonaparte. In 1807 he was elected a member of the Institute in the place of Targi, one of the advocates of the Cessation Law. The Archbishop of Paris subjected him to the displeasure of Pius VII., between whom and Napoleon there had arisen much disagreement. Cardinal Maury was a warm and sincere admirer of the emperor, and he not only expressed his cause in the disputes with the head of the church, but took every occasion, which the frequent victories of this chief afforded him, of testifying his gratitude by the expressions of his feelings. In his raptures of enthusiasm, he was soon so much attached to the emperor that he considered himself as the protector of his diocese. These mandates, written in a style of the most florid eloquence, do not remind us of the impressive and energetic orator of the National Assembly; they were severely criticized by the adherents of the ancient régime and by the witty frequenter of the Parisian saloons, who styled them 'archiepiscopal dispatches,' in allusion to their military tone, and their imitation of the style and manner of Napoleon's bulletins.

After the capitulation of Paris on the 80th of March, 1814, Maury was deprived by the Bourbons of the administration of his diocese; and in their resentment for his adherence to Napoleon's fortunes, he was deprived of his power and his church was transferred to the king of Rome. In the retreat on Paris, 1814, the Pope rewarded him for his firmness and powerful support of their tottering throne. He then returned to Rome, where he was imprisoned during one year by the orders of the pope; he was afterwards allowed to live gratis, to receive a pension, and was rewarded after his liberation. He was the author of a treatise upon Sancho, and his relations of the Pope's residence in the castle on the height of Monte-Soracte. In this retreat, deeply affected by the ingratitude of his former party and of the pontiff, to whose elevation he had been instrumental, he did not waver in his renunciation in regard to his own person, his relations, and his property. "Notwithstanding his extraordinary eloquence," says the Duchess of Abrantes, who knew him intimately, the Abbé Maury had been before the Revolution what he was in prostration, what he continued under the empire, a man of talent rather than a man of sense, and a curate of the time of the League rather than an abbe of the reign of Louis XVI. He added that he found himself in the long and disagreeable, but the description she gives of it appears rather a caricature than a portrait. His principal work, Essai sur l'Eloquence de la Chaire, 3 vols., 1805, published after his death by his nephew Louis Siffrein Maury, still maintains its well-merited popularity. His mind was formed to appreciate the eloquence of Massillon, Bossuet, and Bourdaloue, and his criticisms on the French divines are in general as correct and as severe as they are elaborate. In his review, however, of English pulpit oratory he manifests a want of acquaintance with the writings of our most celebrated preachers, such as Jeremy Taylor, Shielock, and G. W. Blunt, and he appears as a living proof of the comparison which he draws between him and Massillon is necessarily most unfavourable to the former. His own Panegyric of St. Augustine is esteemed one of the finest of his eloquence; he writes it conjointly with l'Abbé de Boismont, to be the author of a work entitled ' Lettres sur l'Etat actuel de la Religion et du Clergé de France.' There is a notice of the life of Cardinal Maury in ' L'Ami de la Religion et du Roi,' vol. xii. (Biographie Nouvelle des Contemporains, vol. xiii.; Allison, Hist. of Europe, vol. i.; Mémoires de la Duchesse d'Abrantes; Biographie Universelle Classique, Deuxième Partie, Paris, 1839; Biographie Moderne, vol. ii.; and a curious work entitled Dictionnaire des Girondins, Paris, 1815, in which are fully detailed the political variations of the most remarkable characters of the Revolution and the empire, though sometimes with more sarcasm than truth.)

MAXIMUM IN MACHINES. In all machinery there are certain relations between the moving parts and resistances which are to be overcome, which render the effect produced a maximum with respect to quantity of motion or velocity, which are the time of the performance a minimum.

In investigations relating to this subject it is usual to consider that in every machine there is a certain point at which, if the moving power were immediately applied, and a certain point at which the resistance to be overcome were immediately applied, the effect which is produced by the machine in its actual state. Thus, in a machine consisting of several wheels and axles with which weights are raised by means of ropes passing over their circumferences, the points at which the weight is most immediately...
connected with the moving power and resistance are tangents to the circumstances are those at which the forces are conceived to be applied. Also, if several forces act at once as moving powers, and resistances are to be overcome at once at various points, the resultant of all the forces and that of all the resistances must be taken for the effective moving power and the effective resistance. The points of application of these resultant forces are to be found, and at these points such resultant forces are to be conceived to be applied; the effects of friction, the rigidity of ropes, and every other impediment to the action of the machine, are also to be estimated and applied as additions to the resistance which is to be overcome; and thus a complex machine is reduced to an equivalent mechanical power of a simple form. The velocities of the points at which these resultant forces are conceived to be applied are equal to the velocities of the power and resistance.

The motion in machines may be of two kinds. On the application of force to a machine previously at rest a certain movement is induced, and this movement for a time is accelerative; but in some machines, after a while, the resisting power and the friction of the materials destroy the acceleration, when, unless the machine is subject to variations of force, is as the case with those which are impelled by wind or by the force of men or animals, the movement will become uniform. On the other hand, there are machines which are acted on by a constantly accelerating power, as when a weight at one end of a rope passing over a wheel descends from an elevated place and raises a weight attached to the other extremity.

If the velocities of the points of application of the equivalent forces are uniform, a simple equation will express the dynamical equilibrium of the machine; for, representing the moving power, and V the velocity with which it moves, or the force of resistance and v its velocity, we have in the case of equilibrium

$$FV = fV$$

the first member of the equation is frequently designated the momentum of impulse, and the second the effect produced by the machine.

But the effect of a moving power on a machine in motion is different from that of an equal power on a machine at rest; for the effect produced by any constant power in the former case depends upon its relative velocity, or the difference between its own velocity and that of the machine, and, by Dynamics, is invariable with the square of the relative velocity. Therefore, in order to introduce the absolute effect of a force into the equation of equilibrium in place of the efficient force, there must be given the velocity which would render the force quite ineffectual, as well as the actual velocity of the point of application: let the former be represented by \(V'\), and the latter by \(V\); then \(F\) representing the absolute force when the velocity is zero, and \(F'\) the actual force when the velocity is \(V\) \((F'\) being determined by the weight or resistance which is just sufficient to prevent the power from communicating motion to the machine, and \(V'\) the velocity with which the machine can move when the resistance is zero),

$$F' : V' :: F : (V - V')$$

whence

$$F = F' \frac{V'}{V - V'}$$

Then the first member of the equation \(FV = fV\) becomes

$$F' \left(\frac{V'}{V - V'}\right) = V'$$

or, putting \(v'\) for \(V' - V\), which gives \(V = V' - v'\), it becomes

$$F' \left(\frac{v'}{v'}\right) = (V' - v')$$

Now, in order to find the velocity which is consistent with the production of the greatest effect by the machine, this expression, which represents the equivalent of \(f\), the effective action of the machine, is to be a maximum; therefore, differentiating that expression, \(v'\) being the variable, and making the result zero, we have

$$2V' - 2v' = 0$$

and, substitution, \(V = \frac{1}{3} V'\).

Hence, if the resistance opposed to the machine is susceptible of being varied, it should be rendered such that the velocity \(V\) of the point of application of the equivalent force is one-third of the greatest velocity \(V'\) which the power can produce if unresisted. Substituting this value of \(V\) in the above equation for \(F\) we get \(F = \frac{4}{9} F'\); therefore \(F\), the momentum of impulse, or the effect of the machine, becomes \(\frac{4}{9} F'\) when that effect is a maximum, the resistance remaining unaltered.

If two bodies are connected together by a flexible line (supposed to be without weight) passing over a pulley at the common summit of a doubly inclined plane, the parts of the line being parallel to the surfaces of the two planes; the relation between the weights may be determined so that the momentum of that which is to be raised by the descent of the other may be a maximum. Let \(p\) and \(w\) be the weights of the bodies, or the forces of gravity acting on them vertically, and let \(\theta\) and \(\theta'\) be the respective inclinations of the planes on which they are placed, to the horizon; then \(p\sin \theta\) and \(w\sin \theta'\) are the forces of gravity on the planes, and consequently

$$p\sin \theta + w\sin \theta' = \frac{p + w}{p + w}$$

is the accelerative force by which \(p\) descends.

Now, by dynamics, the velocity of a body varies with the force and time; therefore, \(v\) representing the velocity of \(p\) or \(w\), and \(t\) the time of motion,

$$v = \frac{p\sin \theta - w\sin \theta'}{p + w}$$

and consequently the momentum \(m\) varies with

$$p\sin \theta - w\sin \theta' = \frac{p + w}{p + w}$$

this expression to be a maximum; therefore, differentiating it, \(v\) being the variable, and making the result equal to zero, the value of \(w\) may be found in terms of \(p\) by a quadratic equation; thus the required relation may be obtained.

If it were required to find, in any machine which when reduced to its most simple state may be considered as a lever or a wheel and axle, the ratio of the velocity of the moving power to that of the resistance to be overcome when the latter is a maximum, the following process may be used.

Let the arms of the supposed lever, or the semidiameters of the supposed wheel and axle, be represented by \(r\) and \(r'\), the power \(p\) being applied at the extremity of \(r\), and the resistance \(w\) at that of \(r'\). By the nature of the lever, \(p = w\) in the case of equilibrium; therefore, when the power is such as to produce motion, the motive force may be expressed by \(p'\) or \(w'\) and if applied at the extremity of \(r\). Now, in order that the momentum of inertia of \(w\) at a distance \(r'\) from the fulcrum may be made equivalent to the momentum of inertia of a body at a distance \(r\), on representing such body by \(p'\), we have \(p' = w' = \frac{r}{r'}\); whence \(w' = \frac{p'}{r'} = \frac{p}{r}\); the whole inertia to be overcome, if applied at a distance \(r\) from the fulcrum, will therefore be \(p + w\) and the accelerative force at the extremity of \(r\) will be

$$\frac{p + w}{r}$$

But, by dynamics, the velocity of a body varies with the force and time; therefore, representing the velocity at the end of the arm \(r\) by \(v\),

$$v = \frac{p + w}{r + r'}$$

and, in order to obtain the velocity at the end of the arm \(r\), the expression for \(v\) must be reduced in the ratio of \(r\) to \(r'\); therefore the velocity at the latter extremity varies with

$$\frac{r'p + w'r}{r'p + w'r'}$$

This expression is to be a maximum; therefore, on differentiating it, \(r'\) being the variable, and making the result equal to zero, there will be obtained the ratio of \(r\) to \(r'\) (which is the same as that of the velocities of \(p\) and \(w\)) consistently with the condition that the velocity of \(w\) is a maximum.
MAXIMUS, RUTILIUS, a Roman jurist, whose period is uncertain, but he probably wrote under Severus and Caracalla. The only work of his mentioned in the Florentine Index is Ad Legem Fuldalidum, or a commentary on the Lex Punicorum Servillian (Parker, 126). There is one excerpt from Maximus in the Digest. Q. CORNELIUS MAXIMUS, a contemporary of Cicero, was the master of C. Trebatius Testa, the friend of Cicero and Epicurus. He was born to two plebeian parents (Liv., xii; Suet., Aug., 2, 4, s. 45). There is no excerpt from his writings in the Digest, but he is once cited by Alfenus Varus (Dig., 33, tit. 7, s. 16), who prefers his opinion to that of Servius on the question that has been involved with the "instrumentum," the word "instrumentum" comprised the rakes, spades, poles, and stakes.

MAY-FLY, the popular name of the Neuropterous insects of the genus Ephemerides and its allies. [Ephemerides, P. C. S.] Boeis (referred to Mayfly in P. C.) is one of the genera of Ephemerides. The Boeis venomosus, an insect inhabiting a great part of Europe, is the type.

MEAR, SIMON, a composer of great repute during the later part of the last, and early in the present century, was born in Bavaria (at Sandersdorf, in 1760, according to Gerber; at Meersburg, in 1768, as stated by Lichtenhahn), and at an early age sent to study music in Italy; in which country he passed the greater portion of his life, and died his last breath. In 1802 he was chosen as Maestro di Capella to the church of Maria Maggiore in Bergamo. In 1799 appeared in Boeis' name the title of the Boeis Pestis, and in 1800 the title of the "Il Fanatico per la Musica." In 1802 he produced his "Misteri Eletasini," which on the Continent has always been regarded as one of the first class, though we believe it never reached this country. Boeis has prepared the way for the reception of Mozart's compositions in Italy, by the introduction of richer harmony and fuller and bolder accompaniments. In 1808 he brought out, at Vienna, "L'Equivoco," an opera buffa; and in the same year 'La Ginevra di Scocia,' founded on the episode of Ariodante, in the "Orlando Furioso," which yet possesses the Italian lyric stage. Boeis' Elisabetta, a "Alessandro ed Adesilia," and "La Rosa Bianca, e la Rosa Rossa," the subject of the latter from the history of our wars of the Red and White Roses. But the greatness of his conceptions, and the most striking proof of the energy of his mind, are evidenced in his serious opera, "Medee," first made known in London by Madame Pasta, whose personation of the Sorceress of Colchis was by all acknowledged to be one of the finest histrionic efforts that any stage in any country had exhibited, and who did no less justice to the vigorous music of the composer than to the classical taste of the poet, the living and well known Signor Rosetti, who built his drama on the foundation of this great work.

The bold determination of Mayer (and also of Paer) to draw more effects from the orchestra—to give to his compositions a higher colouring, as well as deeper contrasts of light and shade, than has been done before—by no means at first with much opposition from the studious non-professionists, and, through their influence, from the public generally. But the enlarged powers of the art thus obtained soon became apparent, overcame all resistance, and the Italy of our day adds another to the numberless instances of one extreme passing into its oppoite; for the clausure of all kinds of braying instruments at present supplies the want of invention, even more than in playgarden. Hence what Grevy unjustly and captiously, if not unjustly, said half a century ago—that Mozart placed the statue in the orchestra, the pedestal on the stage—may now with the strictest propriety be affirmed of real music. In addition to that the statue exhibits nothing but distorted features and false proportions. Mayer died December 2nd, 1845.

MAY-TREMSH (Mrs., F. C.)

MAYNE, JASPER, was born in 1604, in Devonshire. After having continued at Westminster school till nineteen years old, he was entered as a scholar of Christchurch, Oxford; and in 1631 he commenced M.A. Taking holy orders, he became the chaplain of Bishop Willoughby of Durham, and was at two livings in the neighbourhood, continued to reside in the university. He was created D.D. in 1644. Firmly de
to his duties, he was the coadjutor of his bishop in the see of Durham in 1648, and soon lost both of his vicarages. But his spirit was unbroken; and in 1659 he held a public disputation with a noted Anabaptist preacher. Afterwards he resided, till the Restoration, as chaplain in the family of the Earl of Devonshire. In 1660 he was restored to his livings; he then became chaplain in ordinary to the king, a canon of Christ
curch, and archdeacon of Chichester. He died at Oxford, in 1672, and was buried in the aisle adjoining to the choir of Christchurch. The following is a list of his pamphlets, in a part of a part of Lucian's Dialogues; and also several sermons and scattered poems. But he is now remembered only through the humour which marked his conversation, and which gave him the title of "The Old Cicerone." (1. The Old Cicerone; 2. The Old Cicerone, folio, 1668, 4to.; 1669, 8vo.; and in the ninth volume of Dodsley's Old Plays; a work considerably more amusing than decorous, and especially lively in its satire on the Purrism (wine); 2. The Amorous Warre, a tragi-comedy," 1644, 4to.)

MAZZOLINI, LODOVICO, a celebrated painter of Ferrars, sometimes called Lodovico Ferrarese, was born about 1481. Mazzolino, like several other distinguished painters not Florentines, owing to the silence of Vasari regarding them, has only recently received his due meed of praise. His name is sometimes confounded with Mazzolino, a name given by Lomazzo to Parmigianino, as the diminutive of Mazzolino, and Vasari has noticed him slightly under the name of Malini, whence, says Lanzi, he has been divided into two—Malini and Mazzolino, and treated as two distinct scholars of Lorenzo Costa, instead of one and the same; an error which has been corrected by Baruffaldi, the historian of the Ferrarese painters, who appears to have had very imperfect knowledge of him. Mazzolino was nevertheless, in pictures of small dimensions and small figures, of his finest works, considered by the great Italian painters. His works are miniature altar-pieces, and are excellent in colour, light and shade, and expression; and even in composition they are equal to those of their style, the symmetrical. They are on the whole little inferior to the small works by Garofalo. Mazzolino generally painted architectural backgrounds, and these are remarkable for the beautiful detail of the ornaments and figures in baso-relievo which are introduced into them. He died at Ferrars in 1530.

The works of Mazzolino are not numerous. There are several in the Ditchfield Gallery at Dover, and four in the Gallery of Berlin, among which is a valuable large picture on wood, of Christ disputing with the Doctors; it is marked MDXXIV. Zonar Lodovicii Mazzolins Ferrarimuthus. There are two also very characteristic works of this master in the National Gallery, in London; and two in the Gallery of Bologna. Besides these, there are very few authenticated works by this painter, many being no doubt ascribed to other masters, especially to Ghirlandajo, as is the case with a beautiful Nativity in the Florentine Gallery.

(Lanzi, Storia Pittorica, &c.)

MECCA, the birth-place of Mohamet, and the holy city of the Mohammedans, is situated in the part of Arabia which is called El Hedja or Hedj, about 21° 30' N. lat. and 40° 20' E. long., and seventy miles from the Red Sea, in a straight line.

This city is situated in a narrow and sandy valley, the main direction of which is from north to south. The breadth of the valley varies from one hundred to seven hundred paces: the chief part of the city is placed where the valley is widest. In the narrower part are single rows of houses only or detached shops. The town itself, or that part where the houses are contiguous to one another and constitute one mass, covers a space of about fifteen hundred paces in circumference, not the whole extent of ground comprehended under the denomination of Mecca amounts to three thousand five hundred paces in length. The mountains enclosing the valley are from two to five hundred feet in height, and the valley extends gently towards the south. Most of the town is situated in the valley itself, but there are some parts built on the sides of the mountains, especially on the eastern chain. The streets of Mecca are in general broader than those of eastern cities, the houses lofty and of stone, and the numerous windows that face the streets give them a more lively and European aspect. The houses present few windows towards the exterior. Many houses are three stories high. In most towns of the Levant the narrowness of the streets contributes to their coolness, and the frequent use of high carriage is not used, a space that allows loaded camels to pass is considered sufficient. In Mecca it was necessary to leave the passages wide for the visitors who crowd here.

The only public place in the body of the town is the large

2 N 2
square of the great mosque, which is only culverned during the Hadj (Pilgrimage) by the great number of well-stored shops. The streets are all unpaved, and in summer the sand and dust are as great a nuisance as the mud is in the rainy season, during which they are scarcely passable after a shower.

Mecca is badly provided with water; there are few cisterns for receiving rain, and the well-water is too brackish, except for culinary purposes, though during the time of the pilgrimage the lowest class of hadjis drink it. The famous well of Zouzem in the great mosque is indeed copious enough to water a town, but the water is not well tasted, and there is no well enough north to supply the women and children. The best water is brought by an aqueduct from the vicinity of Arafat, six or seven hours distant. This aqueduct is wholly built of stone, and all those parts of it which appear above the ground consists of a thick cover of stone and cement. There are two places in the interior of Mecca where the aqueduct runs above ground, and in those parts it is let off into small channels or fountains, at which some slaves of the sheriffs are stationed to exact a toll from persons who fill their water-skins.

All the houses in Mecca except those of the principal and richest inhabitants are constructed for the accommodation of lodgers, and divided into numerous separate apartments, each consisting of a sitting-room and a small kitchen. Since the pilgrimage has begun to decline, numerous buildings in the outskirts have fallen into ruin, and in the town many houses are in decay. Excess of population seems to have been the cause of their ruin. Some are moated by a ditch, which is said to have belonged to the sheriffs, two mechness or colleges, and the mosque. Mecca has no public edifices, and in this respect is perhaps more deficient than any other Eastern city of the same size. Burchhardt was told that the want of splendid palaces in Mecca is not due to the want of means. The great revenue from the pilgrimage and the jizyah is largely devoted to the veneration which the inhabitants entertain for their temple, and which prevents them from constructing any edifice that might possibly rival it.

Mecca is entirely separate from the Kaaba, which is only removable; for there are several mosques in other places of the East nearly equal in size and superior in beauty. The Kaaba stands in a small square, and is surrounded by colonnades; on each side there are four rows of pillars and on the other sides only three. They are united by pointed arches, every four of which support a small dome, plastered and whitened on the outside. The number of these domes is one hundred and fifty-two, and that of the pillars is variously stated at four hundred and fifty and five hundred. The columns are from one foot and a half to one foot and three-quarters in diameter, and above twenty feet in height, but otherwise there is little regularity in them. No two columns are exactly alike. The capital of these columns is of stone, and is deeply indented; on the lower part there is a circular arch and a column of stones meeting it. The whole area of the Kaaba is covered with a roof of the same material as that which surrounds it. There is a descent of eight or ten steps from the gates on the north side into the platform of the colonnade, and of three or four steps from the gates on the south side. Towards the middle of this area stands the Kaaba, which, according to the belief of the Mohammedans, was constructed in heaven two thousand years before the creation of the world, and Adam, the first believer, erected the Kaaba upon earth on its present site, which is exactly below the spot which it occupied in heaven. It is an oblong massive structure, eighteen paces in length, fourteen in breadth, and from thirty-five to forty feet in height. It is constructed of the great stone blocks of dimahat, joined together in a very rough manner and with bad cement. It stands upon a base two feet in height, which projects a sharp inclined plane. As the roof is flat, it has a distance of the approach to a perfect cube. The only door which leads into it is opened only two or three times in the year; this door is on the north side and about seven feet above the ground; it is entered by wooden steps. At the north-eastern corner of the Kaaba, near the door, is a head of stone; it forms a part of the sharp angle of the building, and is five or five feet above the ground. It is an irregular oval, about seven inches in diameter, with an undulating surface, composed of many smaller parts, and of various colours and shapes, well joined together with a small quantity of cement and perfectly smoothed. Every pilgrim kisses this stone. As its surface has been much worn by the kisses and touches of the people it is difficult to determine the nature of the stone. It appeared to Burchhardt to be a lava, containing several small extraneous particles of a whitish or of a yellowish substance. The colour is now a deep reddish brown approach to burnt ochre, though the surface is not well polished. The four sides are covered with a black silk stuff, hanging down and leaving the roof bare. This covering is renewed annually at the time of the hajj, and is brought from Cairo, where it is made at the express command of the Viceroy of Egypt. It is supposed to produce the wavering of the covering. Seventy thousand angels have the Kaaba in their holy care, and are ordered to transport it to Paradise when the trumpet of the last judgment shall be sounded.

There are several other buildings within the area of the mosque, mostly appropriated to reading rooms, prayer-chambers, or the performance of devotions. The Zouzem, or holy well, is supposed to be the spring found in the wilderness by Hagar, at the moment when her infant son Ismael was dying of thirst. It seems probable that the town of Mecca owes its origin to this well; for many miles round no sweet water is to be found, and the inhabitants are said to have purchased copious a supply. It is enclosed by a square building of massive construction, with an entrance to the north opening into the room which contains the well. This room is beautifully ornamented with inscriptions, and the air is invigorating. It is joined to the outer court, but having a separate door, is a small room with a stone reservoir, which is always full of Zouzem water; this is the hajjis get to drink by passing their hand with a cup through an opening in the roof, which serves as a window. This, into the reservoir without entering the room. From before dawn till midnight the room is constantly filled with visitors. It is considered a miracle that the water of this well never diminishes, and the continual draught from it. Burchhardt learned that the water flows at the bottom of the well, and that it is supplied by a subterraneous rivulet.

The revenue of the mosque is considerable, there being few towns or districts of the Turkish empire in which it does not possess property in land or houses; but the rest of this property is often withheld by the provincial governors, or at least it is reduced by the hands through which it passes, to a small proportion of its real value.

The inhabitants of Mecca, with few exceptions, are Arabeans from different countries; but they have amalgamated, and they wear the same sort of dress, have adopted the same customs and have two classes of expatriates, trade and the service of the Beulah; but the former has the preference, and there are very few ulema, or persons employed in the service of the plain. The town is a receptacle for the religious affairs, though they are too proud to pursue them openly. Pursue the exception of a few potteries and dyeing-houses, the people of Mecca have not a single manufacture. During the hajj Mecca becomes one of the largest fairs in the East, and certainly the most interesting, from the variety of nations which frequent it. The merchants of the place make large profits during this time by their merchandise. They have also a considerable trade with the Bedouins, and especially with the inhabitants of the towns of the Nodj, who are in want of India goods, drugs, articles of dress, and corn. The greatest profit however is derived from supplying food for the pilgrims. The consumption of grain is much greater in Arabia than in any of the surrounding countries, for the great mass of the population live almost entirely on wheat, barley, lentils, and rice, and use no other article of food except a little of butter. The wholesale merchants are very rich, and have establishments at Jidda, whence they receive nearly all their merchandise.

Mecca was, up to recent times, governed by a sheriff, who was raised to his office by the famous family of the Nodj, and the consent of the powerful sherif families of Mecca. He held however his authority from the Turkish Sultan, who invariably confirmed the individual who had got possession of the government. The revenue of Arabian, trade and the demand for grain diminished, and the Nodj was no longer able to send large armies with the hadj caravans, the sherif of Mecca became entirely independent, and disregarded the orders of the Porte. But Mohammed Ali of Egypt has restored the
authority of the Osmanis in the Hadjia, and unwound all the power of the sheriff, allowing to the present sheriff a merely nominal sway. The sheriff is chosen from one of the many tribes of sheriffs, or descendants of the Prophet, who settled in the city; the selection was, of course, made by and reduced to a few families of Mecca. The succession is not hereditary, but although it seldom takes place without some contest, there is little bloodshed in general; and though instances of cruelty have occasionally occurred, the principles of honour and good faith which distinguish the wars of the Desert have generally been observed.

(Burchhardt's Travels in Arabia; Allrey's Travels in Modern Turkey, Tripoli, Cyprus, Egypt, Arabia, Syria, and Turkey.)

MECHANICAL POWERS is the name given to certain simple machines or engines, for these words are applied indifferently, either of which is occasionally used by itself in moving bodies or raising weights, or any of which are combined together in the formation of the complex constructions which are employed in manufactures and the arts. Frequently however, in investigations relating to statical equilibrium, the properties of the mechanical powers are introduced when no machine is contemplated; as when, at some part of a plane surface, the effect of a pressure at another part is determined by the ratio of the distances from a supposed point of support. The several machines to which the name of mechanical powers is applied are the Lever, the Wheel and Axle, the Inclined Plane, the Wedge, the Screw, and the Pulley. Each of these has several forms, which are described under those words in the body of this work, and the last in the Supplement.

The object proposed in every machine is to transmit a force from one point to another; and it is immediately applied to that at which some resistance is to be overcome or some operation to be performed; and, in the transmission, the intensity of the motive power is to be increased so that effects may be produced which could not be accomplished by that power alone. The increase of the power is obtained by causing part of the resistance which is to be overcome to rest on the machine or on an object by the aid of the machine, which is used for its support, but such part which remains is opposed to the motive force. Thus, if it be required to raise a heavy body to a certain height from the ground, no exertion of human or animal strength may be sufficient, if directly applied, to accomplish the end; but if a plane inclined to the horizon and extending from the object to the spot to which the latter is to be raised be formed, and the object can be placed on its foot, the force of gravity in the vertical direction being resolved into two forces, one of which is destroyed by the reaction of the plane, the other may be overcome by a motive power less in intensity than that which would be required if a direct application of force were made; in other words, the distance over which the expenditure of the end diminishes in proportion as the length of the plane is greater.

The manner of overcoming a resistance, which is specified in the preceding, is a mechanical contrivance, and it is evident that in every application of a mechanical contrivance to overcome a resistance, as much advantage is lost in respect of time or space as is gained in respect of power. For it is evident that, in order to raise the object vertically through a space equal to the height of the plane, it would be necessary to move it over a space equal to the length of the plane; that is, through a space which bears the same ratio to the vertical height as the weight of the object bears to the power required to move it up the plane.

An account of the applications of the mechanical powers in the construction of complex machines would involve descriptions of many objects, some abridged and dispensed with; and therefore the reader is referred to works in which machines or engines are expressly described, as Gregory's 'Mechanics,' vol. ii., and Barlow's 'Practical Mechanics,' in the 'Encyclopaedia Metropolitana.'

In determining the efficacy of the mechanical powers it is evidently necessary to consider their parts as mathematical lines, and to treat all of them connected together without rigidity, so that a perfect equilibrium may subsist in the machine itself before the moving power is applied. The most simple lever, for example, of a physical kind, is a rod or plane, which is acted on by two forces of equal magnitude in the fulcrum, are of unequal weights; and, in order to reduce such a lever to a state from which the exact relation between the opposing powers may be found, the weight of each arm must be computed, and being, in imagination, applied at the centre of gravity of the arm, the product of the weight multiplied by the distance of the centre of gravity from the fulcrum is to be added to the moment of the weight against the fulcrum, and hence the moment of the two forces which would be equivalent to them, at any given instant, the principles of honour and good faith which distinguish the wars of the Desert have generally been observed.

(MECKENEN, MECKENEN, or MECHELN, ISRAEL VAN, a celebrated Dutch goldsmith, born in the fifteenth century, born probably at Meckenen near Bocholt, in the bishopric of Münster, though this is a matter of speculation, and his name is written in a great variety of ways, but the above form has met with most supporters, as it is found written in full on his tombstone and upon two of his prints: some however have supposed that the engraver and painter were two distinct artists, or that Israel van Meckenen is not Meister Israel the painter mentioned by several old writers. There are eighteen beautiful old oil-paintings in the Pina-kohak at Munich, and some in other collections, which are attributed to Meister Israel; they are of the Van Eyck period, and most of them have been found in the neighbourhood of Cologne and Cleebuzen, which is one of the reasons for concluding that Meckenen in Westphalia was the artist's birthplace, notwithstanding Meckenen near Born is in the very district in which these paintings have been found. There is very good evidence in favour of Meckenen, as Israel was buried at Bocholt, and he appears to have resided there. In Ottley's 'Early History of Engraving' there is a print from a drawing in the guild house at Cleebuzen of Israel van Meckenen's tombstone (since lost), which contains an inscription in the old Gothic character to the following purport.—'In the year of our Lord 1506, died Master Israel van Meckenen; his soul rest in peace. In 1507, a year and a half after his death, an engraver was born, whose name is v. M.: v: en: ijij: up: sinte: meritijnas: avend: staat de: erber: meister: Israel: v: Mecken: a: siete: roste: in: vraste.' Israel Van Meckenen was evidently an engraver, from the signatures on his numerous prints, and we know him to have been a goldsmith, from accounts in the old Bocholt records in which his name occurs, from 1482 to 1486 inclusive; but he is on no occasion mentioned as a painter. Yet a painter of the name of Israel is mentioned by several writers, and among them by Jacob W Answer...
Ishmael alone. He has engraved his own portrait twice: in one, his name is signed in full ‘Ishavel van Meckenen, goldsmith;’ the other, in which his wife is also engraved, is marked ‘Francesca of Isavel d’Ido.’—I. V. M.

The pictures attributed to Ishavel van Mecken, upon what authority is not explained, are all upon gold grounds and upon panel. They are some of them on a large scale, many of the figures being 36 inches high. The size of life, in an execution so easy to equal any works of their style extant; their expression is often excellent, and the colouring very clear, forcible, and effective. The Ascension and Coronation of the Virgin, Josiah and Caleb at the golden gate, and several pictures of Apostles, in the Pinacothek at Munich, are very beautiful works, and if by Vanc Mecken enhances, he is evidently entitled to rank with the Van Eycks, Wilhelm von Köln, Hans Burgkma, the younger, Lucas van Leyden, and other distinguished masters of that time and school. Some of these pictures were drawn in lithography, in 1822, by N. Strixner. The supposed signature of Van Mecken, with date, on a picture in the gallery of Vienna, mentioned in the catalogue of von Mechel, is according to Bartisch an error.

(Heineken, Neue Nachrichten von Künstler und Kunstfreunden; Florio, Geschichte der Zeichnenden Künste; etc.; Bartisch, Pastror-Gemälde; Becker, Künstlerblatt, 1859; Nagler, Neues Allgemeines Künstler-Lexicon; Dillig, Gemäde in der Königlichen Pinakothek zu München; Brillot, Dictionnaire des Monuments, etc.)

Medicus, an apricot, a poppy, and cory, a resemblance, a genus of plants belonging to the natural order Papaveraceae, and formerly referred to Papaver. This genus stands between Papaver and Argemone. It has 4 petals, numerous stamens, a short style, and free stigmas; the capsule obvate, opening by pores beneath the apex.

There is but one species, M. Cambrica, the Welsh Poppy, and this is native of Great Britain, but it is a rare plant. It is also found in many parts of Europe. It has yellow flowers which are very fragrant, and are seated on long peduncles which are reflected before the opening of the flower, so that the flower-bud is drooping. It is an ornamental plant, and may be grown in the garden. It grows in a rich, light soil, in a shady situation. It may be propagated by dividing the roots, or by seeds.

MEDICAGO (from μέθαλος, the Greek name of one of the species), a genus of plants belonging to the natural order Leguminoseae, to the tribe Loteae, and the subtribe Trifoliolae. It has the calyx somewhat cylindrical 5-clawed, the keel rather removed from the vexillum; the stamina dimorphous; the legume many-seeded, of various forms, reniform, falcate, or coleolate, but usually twisted in a spiral manner. The species are herbs or shrubs, with the stipules usually cut; the leaves trifoliolate, the leaflets usually toothed, and the peduncles 1-2-branched.

M. sativa, Lucern, has many-flowered racemes; the pods contain 3 seeds; the flower is white in three, tawny, downy; the flower 3 armed; the pod-capsule shorter than the calyx and the stem; the leaves obvate-oblong, dentate above, marginated. This plant is a native of Europe, and is found wild in England and Scotland. It has an erect stem, with yellow or violet flowers. It is commonly cultivated in the fields of Europe (Lucassen, P. C.), and Babington says that ‘the wild specimens found are scarcely naturalized.’ This is the index of Theophrastus, ‘Plant, de Caus.’ lib. 2, cap. 20; and the Medicota of Flinay, lib. 18, cap. 10.

M. falcatoides has the racemes many-flowered, the pods compressed, sickle-shaped, downy, unarmed; the pedicels shorter than the bracteoles; the leaflets oblong, dentate above, marginated, mucronate. It is a native of Europe on dry mountainous pastures. In England it is a rare plant, but it is occasionally found on dry gravelly banks and old stone walls. It is said to be the Lucern which is cultivated in Switzerland.

M. leucophylla, Black Medick, or Black Nonsuch, has many-flowered denser oval spikes; the pods compressed, kidney-shaped, furrowed and pointed, and with prominent veins; the stipules obliquely ovate, slightly toothed; the leaflets roundish-obovate, dentate above, marginated, mucronate. It has a procumbent stem with yellow flowers, and grows in pastures, in hedgerows, and on waste grounds, and is plentiful in Great Britain. It affords excellent fodder for sheep, and must be treated in the same way as lucern.

M. arbores, Tree Medick, is a villous straberry plant; it has ovate-corolldated leaflets nearly entire; the stipules linear, acute, entire; the peduncles racemose; the legumes stipitate, twisted, reticulated from transverse veins; 2-3-seeded, the seeds roundish-ovate, 2-3-branched, of the size of those of the south of Europe, and appears to be the sertura of Theophrastus, ‘Hist. Plant.’ lib. 4, cap. 5; lib. 1, cap. 9; ‘De Caus. Plant.,’ lib. 6, cap. 6; and the sertura of Dioscorides, lib. 4, cap. 28; of Flinay, lib. 13, cap. 24; Virgil, ‘Ecl.’ 1. 79; ‘Georg.’ ii. 431.

Besides the first species, described above, M. maculata, M. minima, and M. denticulata are natives of Great Britain, and occur in several places. They are not very common in the British Flora as growing on the sea-shore at Orford in Suffolk; Mr. Babington, in his Manual, states that he is convinced, from personal observation, that no such plant now exists in this country.

In cultivation the species may be easily raised from seed, and the shrubby species propagated by cuttings. The perennial herbaceous species may be propagated by dividing their roots.

(Babington, Manual Brit. Bot.; Fuss, Synopsis Plantarum Florae Classicum.)

MEDICI, GIAN GIACOMO, Marquis of Mariangino, born at Milan in 1495, was the son of a steward of the Duke of Milan. He entered early the military profession, in which he showed great courage, accompanied with a want of all principle. In the war between the Italian Powers and the Empire, for the disposal of Lombardy, Medici took the part of his countrymen, and served under Pescara in the campaign of 1522, in which the French were driven out of Lombardy. He acquired the confidence of the Emperor Charles V., who employed him to murder Astorre Visconti, a descendant of the former dynasty of the dukes of Milan, who gave umbrage to the actual occupant of the ducal throne. Medici, having committed the deed, was sent to assist in receiving the castle of Musso, situated in the mountains above the lake of Como, which was still held by the French. He succeeded in taking possession of it, and he kept it for himself for years; he often, for the Emperor, drove the garrisons out of Italian territory, and making predatory incursions among his neighbours. When Francis I. again invaded Lombardy, in 1525, Medici made an incursion into the Valtellina which belonged to the Grisons, and took possession of Chiavenna. The Grisons, alarmed for their own country, recalled their troops which were serving as auxiliaries in the French camp, and this defection is said to have contributed to the defeat of King Francis at Pavia. In consequence of this service, Medici was acknowledged by the duke as feudalatories of Musso and other places, with the title of Chatelain.

In the subsequent quarrel between Duke Sforza and his overbearing brother, Medici put himself at the head of the disaffected Milanese emigrants, and annoyed the Spaniards, but after a time, the Spanish governor of Milan, Don Antonio Caracciolo, retrieved his former confidence. Medici was then raised to the title of Marchese of Musso. The object of Medici was to carve out a principality for himself at the expense of his neighbours. He again invaded the Valtellina and took Morbegno. At last, in the year 1532, Duke Sforza, partly by force, and partly by offering him a sum of money with an annuity, the past, made him give up Musso and his other strongholds. Medici then retired to Piedmont and entered the service of the Duke of Savoy. Here his career as an adventurer terminated. Medici afterwards served in the campaign of 1536 against the French in Piedmont. Having returned to Milan after the death of Duke Sforza, he was made Marquis of Marignano, by the Emperor Charles V., and in 1539, when he accompanied Charles in his expedition against the revolting Flemings, from thence he went to Hungary to fight for the emperor against the Turks, and afterwards he served in Germany under Charles himself against the Duke of Saxony. Returning to Italy, Medici was appointed to the command of the expedition against Siena, which city he took after a long siege in the year 1545. On his return he was received with the highest honours, and eventually he was created Duke of Musso, with great honour, and on this occasion his relationship to the Medici of Tuscany was acknowledged by Cosmo, notwithstanding which it is still greatly doubted, or rather disbelieved. He married to his second wife, in 1540, Pia, daughter to Giovanni Angelo Medici having become pope, in 1565,
by the name of Pius IV., built him a splendid monument in the
cathedral of Milan, whither his remains were transferred.
Of the monarchs of that line who succeded him none rose to
commanders of the age of Charles V., but was likewise one of
the most unprincipled, rapacious, and cruel.
(Misgina, Vita di S. Jacopo Medici, Marchese di Marigna-
poli, 1660.)
MEDINA, the second holy city of the Mohammedans,
and the place where their Prophet was buried, is situated in that
province called Mekka or Hejaz, or Hej, about 25° 15' N. lat.
and 35° 40' E. longitude, being thirteen miles from the
town of Yembo on the Red Sea, which is the harbour of
Medina.
Medina is built on the elevated plain of Arabia, not far
from the eastern base of the ridge of mountains which divide
the table-land from the lower country between it and the
Red Sea. The town stands on the lowest part of the plain,
in which the watercourses unite, which produce in the rainy
season numerous pools of stagnant water, and render the
climate unhealthy. Gardens and date-plantations, inter-
spersed with fields, enclose the town on three sides; on the
side towards Mecca the rocky nature of the soil renders cul-
tivation impossible.
The city forms an oval about 2800 paces in circuit, ending
in a point. The castle is built at the point on a small rocky
crane, and is enclosed by a wall of about three and a half
hundred yards long. The interior walls are whitewashed all around, except the southern
one and part of the south-eastern corner, which is casued with
slabs of marble, nearly up to the top. The floor under the
principal colonnades on the western side of the town,
which is to the north, has a coarse pavement and is nearly covered with sand,
as is likewise the open square. On the southern side the
whole is paved with fine marble across the whole colonnade,
and in those parts nearest the tomb of Mohammed this pave-
ment is of mosaic, of excellent workmanship. Large lofty
windows, with glass panes, admit the light through the
south wall; some of them are very well painted. On the
other sides there are smaller windows along the walls, but they
are neglected.
Near the south-eastern corner of the mosque stands the
famous tomb, detached from the walls so as to leave between it
and the southern wall a space of about twenty-five feet, and
fifteen between it and the eastern wall. The enclosure which
procts the tomb from visitors, forms an irregular square of
about twenty paces, in the midst of the colonnade, several of its
pillars being included within it; it is an iron railing painted
green, about two-thirds of the height of the columns. The
railing is of good workmanship in imitation of filigree, and
is decorated with open-worked inscriptions in yellow bronze.
It is of so close a texture that no view can be gained into the
interior except by several small windows, about six inches
square, which are placed in the four sides of the railing, about
five feet above the ground. On the southern side, which con-
forms to the sides of the mosque, there is an opening, divided
from the rest by a railing, so that one can stand when praying, the railing is thinly plaited over with silver,
and the inscription 'There is No God but God, the evident
truth," is repeated in silver letters across the railing.
This enclosure contains four large porticoes, each with four
gates, three of which are constantly kept shut, and one only
is opened every morning and evening to admit the eunuchs,
bring the body to the chamber at the foot of the dome

The enclosure is called El Hejira. Permission to enter it is
granted gratis to people of rank, and may be purchased by
other people, from the principal eunuchs, for about twelve
or thirteen dollars; but on entering the enclosure nothing more is
to be seen than what may be observed when peeping at the
windows of the railing. At the distance of only a few paces
from the railing is a curtain carried all round; it is equal in
height to the railing. It is made of a rich stuff of various
colours, interwoven with silver flowers and arabesques,
with a band of inscriptions in golden characters running across
the middle of it. This curtain is a small opening at the northern
end, which is always closed, and no one is permitted to enter within its holy precincts, except the chief
eunuchs, who take care of it, and who put on during the
night the new curtain sent from Constantinople, whenever it
is wanted, or take it off in the morning to let in the light
from the throne. The old curtains are sent to Constantinople, and serve
to cover the tombs of the sultans and princes.
According to the historians of Medina the curtain covers a square building of
white marble, the interior of which are the tombs of Mohammed and his two
earliest friends and successors, Abu Bekar and Omar. These
scrobes are deep holes, in which the coiffs are deposed; that of
Mohammed is cased in silver. The floor between the
curtain and the railings is laid with variously coloured
marbles in mosaic; glass lamps are suspended all round the
curtain, which is lighted every evening and all night.
The whole of the enclosure is covered with a fine
lofty dome rising far above the domes which form the roof
of the colonnades, and is visible at a great distance from the
town and out of sight of the colonnades. As soon as the clergy to Medina catch sight of it they repeat
some prayers.

Near the curtain, and within the railings, is the tomb of
Seita Fatima, the daughter of Mohammed and wife of Ali;
it is a lighted cupola formed and covered with a
richly embroidered black brocade, and without any other ornament.

Mohammedian tradition says, that when the last trumpet
shall sound Aya (Jesus Christ) is to descend from heaven
to earth, and to announce to the inhabitants the great day of
decision; after which he is to die, and will be buried in this
Hegira by the side of Mohammed; that when the dead shall
rise from their graves, they will both rise together and ascend
to heaven, where Aya will be ordered by the Almighty
to separate the faithful from the infidels. In conformity with
this tradition the spot is pointed out through the curtain of the
Hegira where the tomb of Aya will be.

Four gates lead to the interior of the mosque; a few steps
are to be ascended from the neighbouring streets up to the
gates, which are made to look smaller than they really are,
contrary to what is the case Mecca. About three
hours after sunset the gates are closed by means of
folding doors covered with iron, and not opened till about an
hour before sunrise. This is the custom of the place, as the
mosque can easily obtain permission from the mufti on
guard, who sleeps near the Hegira. During Ramadhan
the mosque is kept open the whole night.

The inhabitants of Medina, like those of Mecca, are not
Bedouins, but strangers, who have come to the place as pil-
griims and afterwards settled there, or they are descendants of
such strangers. Medina is not so great a place of commerce
as Mecca, and the merchandise are not so rich, but it has the
advantage of having a considerable tract around which is fit
for cultivation, and there are many wealthy landowners in the
town, who let out their possessions to poor people. Wheat
and barley are cultivated, but the chief profit arises from the
plantations of date-trees, the fruit of which is held in greater
estimation than the dates of Egypt.

(Burchhardt, Travels in Arabia.)

MEDITATIO FUGAE WARRANT, in the law of
Scotland, is a writ by which a debtor, supposed to be about
to make his escape from the country, is arrested and kept in
custody, until he pay the debt, or find security to pay it if he
shall not in due time repay it. It deserves no notice from its
being an old consuetudinary practice in Scotland,
which happens to be in union with the late legislation of
England on the subject of debtor and creditor. In Scotland
there is no statute of arrest on the debt; but the law of
England anterior to the 1 & 2 Vict. c. 110, appears to have
been ever acknowledged; and it was only on the
ground that he was about to flee the realm, that a debtor
could be arrested, unless on the authority of a final judgement
of a court of law, or on the extracted registration of one of those
documents in which by a 'cause of registration for execution'
or by commercial custom (as in the case of bills of exchange)
the grantee agrees to put in the position of having a decree
recorded against him. A meditatio fugae warrant may be
granted by any judge having jurisdiction in questions of debtor
and creditor, at the instance of the sheriff, a magistrate of a burgh, a justice
of the peace. When granted by a sheriff, it has, by a
late act, the advantage that it may be executed in any part of
Scotland, whether without or within the jurisdiction of the
sheriff who grants it. (1 & 2 Vict. c. 110, s. 25.)
The grantee of such a warrant is to be kept in the
place, the oath of the creditor, who must distinctly set forth the
amount, nature, and origin of the debt. The debtor is
then brought before the judge, who, hearing the statement of
both parties, must insist on a confession of debt, and if the
magistrate on a distinct oath of debt should refuse to commit,
he is personally liable to the creditor for the consequences,
and the execution of the writ. But, if the debtor, he grants a
warrant on an improbale or incoherent statement, he will be liable in damages
in the person committed. At all events a person desiring a
meditatio fugae warrant is liable to damages if he obtain it on
a false statement. A person imprisoned on such a warrant must
be liberated in six months, unless his further imprisonment
be authorized by other judicial proceedings. By 6 & 6 Wm.
IV. c. 70, imprisonment for any debt under 8l. 6s. 8d. (100l.
Scots) was abolished in Scotland, and it was lately found by
the court of session that meditatio fugae warrants come within the
act.

MEGALICHTHYES, a genus of fossil Ganoid fishes, from the
carboniferous strata of Edinburgh, Glasgow, Leedes, Man-
chester, and Lancaster. (Agassiz, Recherches sur les Pisciens
Fossiles.)

MEGACODON, a genus of fossil Conichthyes, proposed by
Goldfuss, and the Deventer and Dufton. (Goldfuss, Phaen.
MEGAPHYTON, a genus of fossil plants, from the coal-
measurens. (Artis, Antediluvian Physiology.)

MELALEUCA (from Melaleuca, black, and leuca, white), a
genus of plants belonging to the name Myrtaceae. They
have the calyx-tube nearly hemispherical, the limb 5-partite;
the petals 5; the stamens numerous, combined into 5 elong-
bundled, tarsi alternate with the petals; the anthers in-
compact; the style siliquiform, the stigma obtuse; the capsule
conato and enclosed in the thickened tube of the calyx,
which is sessile on, and adnate at its base, to the flower-bearing
branch, 5-seelled, many-seeded; the seeds angular. The
species are trees or shrubs with alternate or opposite ever-
leaves, equal at the base, with flowers perfectly sessile, or
somewhat interpreted with the branch, arranged in spikes or
heads, and of a white, yellowish, or purplish colour.

(M. Glechoma.) Glechoma has the leaves alternate, eliptic-lanceolate, acutish, rather falcatate, 5-
served; the flowers rather distant in spikes, the rachis and
calyces villous. This is the species which yields the chief
oils of Australia, and is fixed under the name of Capej
oil. It is a native of Ambonya and other East India islands.

[Mealaucua Cazepetti. P. C.]

M. Leucodendron, White-tree, or Capej-tree, has alternate
long lanceolate acuminate falgate 5-served leaves; the
flower-bearing branches pendulous; the flowers in spikes
rather distant, which, as well as the rachis, are quite glabrous.
It is a native of the East India Islands, and was at one time
supposed to yield the chief Capej oil. It is a native of
South Africa, and is a shrub that possesses little or no fragrance in its leaves, and that
it is seldom or never used for the distillation of the oil which is
used in the European markets.

Upwards of thirty species of Melaleuca have been described,
the majority of which are natives of New Holland. Many
of them are fine plants with beautiful blossoms, and very
desirable for the conservatory or greenhouse. They grow well
in a mixture of peat, loam, and sand. The leaves are
ragged by cuttings, which will readily take root if planted in a pot of
sand and placed under a hand or bell glass.

(Lindley, Flora Medicus; Don, Gardener's Dictionary.)

MELOSTOMA is a genus of plants belonging to the natural order Scrophulariaceae
or Scrophulariaceae. It has a tubular 4-toothed calyx; a
ringent corolla; the upper lip compressed laterally with reflexed mar-
gin; the lower lip broad; the styles with obclavate appendages;
liquidly acuminate, compressed; one or two seeds in each
carapace. The smooth. It is an annual plant, with opposite lanceolate
linear entire leaves, with opposite usually secondarily
flowers. Eight species are enumerated by Don, six of which
are European and two Americas. Of the six European
four are natives of Great Britain.

M. cristatum, Crested Cow-wheat, has the spikes densely
imbricated, 4-sided, and the bracts heart-shaped. It is a na-
tive of woods and thickets in the eastern counties of
England, and generally also of the north and middle of Europe.
M. arvensis, Purple Cow-wheat, has lax conical spikes,
and ovoid lanceolate atttached leaves. The bracts are of a purpl.
rose-colour; the flowers yellow, variegated with rose-colour
and purple. It is a native in fields of wheat in the south
of Europe, and is found in Great Britain, though only rarely, in
Norfolk and the Isle of Wight.

M. pratense has the flowers axillary, secund in distant
pairs; the calyx closed; the upper lip protruded. It has
large pale yellow flowers. It is a native of Great Britain,
but has not yet been found in a common situation. It is
defined as a species of Scrophularia, with an open calyx,
and lips equal in length. It is a rare plant, and is found in
alpine woods.

(Elbington, Manual of British Botany; Don, Gardener's
dictionary.)

MELASTOMA (from Melanesia, black, and stoma, a
mouth, because the berries when eaten stain the mouth black),
a genus of plants, the type of the natural order Melastomataceae.
It is the tube of the calyx ovate, half-shedding to the ovary, densely covered with scales or bristles; the limb 5-regularly 6-angled, the segments alternating with the appendages, both characters of these species belonging to the petals; the anthers oblong linear, a little arching, opening by a pore at the apex, each furnished with a stiple-formed connective, which is in some species elongated, and in others a little spatulate; the lobes of the limb part of the ovary conical and bristly; the style filiform, somewhat thickened at the apex; the stigma a pruinose dot; the capsule baccate, 6-seeded, opening irregularly; the seeds coarsely spinose. The leaves of this genus are shrubs, which are usually covered with strighe. The leaves are petiolate, and either quite entire or serrulated. The flowers are large, white, rose-coloured, or purple.

Melanotaenia Malabar Melastoma is a shrubby plant with tetragonal branches rough from strighe; the leaves elliptic-oblong, obtuse at the base, acute at the apex, quite entire, green on both surfaces, and scabrous from strighe; the corollas 1-5-flowered; the calyx clothed with asprege strigose scales, with ovate acute lobes, the connectives of the anthers short, or very long. It is the native of the East Indies, and frequent in the Indian Archipelago. The leaves of this plant are employed by the natives, where it grows, as a remedy in diarrhoea, dysentery, and mucous discharges.

Between thirty and forty species of Melastoma have been described. They grow in the warmer districts of the Old and New Worlds. They are found in Asia, in this, and in Africa. Their flowers are very handsome, and all the species may be cultivated for ornament. They grow well in a mixture of loam, peat, and sand, and young cuttings root freely in sand in a sunny place.

(Lindley, *Vegetable Kingdom*; Don, *Gardener's Dictionary*.

MELIC, a genus of plants belonging to the family of Gesneriaceae. It has nearly equal glumes, with lateral ribs, nearly as long as the ovate spikelet of 1 oder 2 flowers rounded on the back, and a club-like rudiment of one or two more; the paleae hardening on the loose fruit; the styles terminal. There are two British species of this genus, *M. uniforma* and *M. maculata*, which are found in damp shady woods.

(Babington, *Manual of British Botany*.

MELLOTUS (from *Medusa*, 'honey', and *larios*, 'lotus'), a genus of plants belonging to the natural order Leguminosae. It has a calyx with five nearly equal teeth, the keel obtuse, the filament filiform, the ovary straight, the pod subglobose or oblong, 1-seeded, 1-seeded, longer than the calyx, the petals distinct, deciduous. The species are herbaceous plants with stipules adnate to the petiole, and trifoliate leaves with usually toothed leaflets. None of them are ornamental plants, but they are valuable for the seed and the cuttings. The flowers of the species are used as fodder for animals.

(Melilot, P. C.) Two species are found native in Great Britain. *M. officinalis*, the common Melilot, has lax racemes, with white to cream-colored flowers; it is a hardy, persistent, and standard equal; the pods ovate, acute, compressed, transversely wrinkled, hairy; the seedlets serrate, truncate, narrow ovate; the stipules setaceous, entire. *M. vulgaris* has the wings and keel equal, but shorter than the standard; the pods ovate, obtuse, mucronate, reticulate, rough, and glabrous. It is a rare plant, and is found in sandy and gravelly places near the sea.

(M. Mesembria). Mesenia Melilot, an erect stem, with ovate-cuneated denticulate leaflets; the stipules broad at the base, toothed, linear at the apex; the racemes few-flowered; the calyx nearly equal, nearly hardy, slenderly -broad at the base, the lanceolate, acute, very much -nerved, 1-seeded; the seed ovate, compressed, large, black, rugged from dots. This plant is a native of Barbary, Sicily, Piedmont, and the Straits of Messina. It is the Melilotus of Thunberg, and is the *L. Maculata* of Dioscorides, lib. iv., cap. 171. It is also the Lotus of the Romans (Pliny, xiii. 17; xxxii. 21; Virgil, *Aeneid*, i. 184, and iii. 934). None of the species of this genus are worth cultivating as ornamental plants. They may be easily propagated by seeds, which should be sown in the open border in spring. A light airy soil, and plenty of water, is requisite for their growth. They are hardy plants, and may be raised from seeds.

(Fras, Synopsis; *Manual of British Botany*; Don, *Gardener's Dictionary*.

MELISSA (from *Melissa*, a bee), a genus of plants belonging to the Labiate or Lamiaceae. This genus has been variously defined according to the different views of systematic botanists. Bentham, in his monograph on the Labiate, has referred about 30 species to this genus. They are all known by the common name of Balms, and some of them are described by Calamintha, P. C. S. The genus thus extended has the following characters:—The calyx is tubular, 13-nerved, usually striated, bilabiate; the upper lip generally spreading tridentate; the lower lip bifid; the tube of the corolla straight or incurved ascending, naked inside, usually exerted, the throat generally inflated, the limb bilabiata, the upper lip erect, flat, entire, or emarginate; the lower lip two to three times as long as the middle lobe usually the broadest, entire or emarginate; the stems 4, didynamous, ascending, approximate by pairs at apex, or rarely a little distant, lower two the longest, the superior two sometimes sterile, the filaments too short, 2-celled, the connective often thickened, the cells distinct, parallel, diverging; the lobes of style sometimes equal, subulate with minute terminal stigmatic; sometimes the lower lobe is elongated, recurved, flattened, with stigmatic margins; the achenia dry and smooth. The species are usually herbs, sometimes under-shrubs, with a variable inflorescence.

The only species of the old genus Melissa admitted into the British Flora is *M. officinalis*, common Balm. It has ovate crenato-serrate acute leaves, pale beneath, the calyx subcampanulate, slightly ventricose in front, distinctly 2-lipped, the upper lip flat truncate, with three short broad teeth, the lower with two, six-toothed, flat. It is a native plant, although it has a place in the British Flora, is a doubtful native. In its recent state it has a rough aromatic taste and a pleasant lemon-like smell. It is frequently used in infusion, under the name of Balm, and in ointments, as a cordial and restorative. It was one of the medicines recommended by Paracelsus, but at the present day it is only used as a popular remedy.

MELLIAN, CLAUDE, a French painter and distinguisher engraver, was born at Abbreville, in 1601. He studied in Rome under the then celebrated Vouet, but he soon gave up painting for engraving, which from that time became his chief business. He remained some years in Rome, and engraved many plates there, executed in the ordinary method of line-engravers. He did not altogether adopt his own peculiar method of engraving by a single line, until his return to France. He latterly executed all his plates by single lines, that is, instead of crossing one set of lines by a second or even a third act, when great depth was required, he completed a similar effect by merely thickening the single set of lines, the varieties of light and shade he produced wholly by varying the thickness of the line. Melian carried this peculiarity to a great extreme here by the use of the spirals, or curves, which he used in his engravings. Although this has given the engraver a facility, it has lost in effect as a work of art: he made two preparatory drawings for this print; one is in the Royal Library at Paris.

Mellian's prints are very numerous: they amount, according to some accounts, to upwards of 500; many of them are after his own designs. His masterpieces are Rebecca at the Well, after Titienette; St. Peter Nolasco borne by two Angels, after a design by himself; and Pope Urban VIII., after Bernini. He enjoyed a great reputation during his lifetime; Charles II. invited him to England, and Louis XIV. granted him an annual pension, and gave him apartments in the Louvre. He died at Paris, in 1664, and was buried in the church of St. Marcouf in the Faubourg St. Antoine, Paris, on the 15th of August, 1664.

(Forent Le Comte, *Cabinet des Singularites, etc.*; Huber, *Manual des Amateurs, etc.*.

MELIOE. The Linnean genus Melioe included the several genera of heterophyllous Coleoptera now forming the family Cantharidae, interesting on account of its including those beetles known under the name of 'blistering flies,' and employed in medicine. The term melanoxylon Lam. refers to the aperous Cantharides, and the species are all beetles with large and swollen bodies, and short ovate elytra, lapping over each other at the base of the suture. They are sluggish insects, feeding on various plants, especially those of ranunculus. When alarmed they emit from the articulations of their legs an oily, yellow, or reddish liquid. Latreille maintained that this insect was the *buprestis of the ancients*; to which various species of Meliloba and related genera were transferred. A paper on the subject in the 12th volume of the *Memoires du...*
The nature of the larva of the melaleuca has been a subject of considerable discussion among entomologists, having been supposed to be a minute, active, parasitic insect living on the trunks of trees. Most entomologists, however, have held this view since the time of Linnaeus, but the observations of Geoffroy, Newport, and Westwood, go far to prove that it is a mistake, and that there is no animal in the case.

MELVILLE ISLAND is situated on the northern coast of Australia, between 11° and 12° S. lat. and 180° and 181° 34' E. lon. It is separated from Bathurst Island, on the coast east of it, by Apley Strait, which is forty-six miles long, and between two and four miles wide. East of the island lies Coburg Peninsula, where a British colony was established some time before 1829. The island is named after Apley, p. 34. Next to it is the eastern end of it, which at the narrowest point is fifteen miles wide. This island is called Dudas Strait. The eastern end of Melville Island is only fifteen miles from the mainland of Australia, and the sea between them was called Clarence Strait by Captain King. It is muddied with small islands, rocks, and reefs, between which run rapid currents. The area of the island may be about 1800 square miles.

The northern line of coast, and also the western, along Apley Strait, are low, intersected by swamps, and covered by impenetrable woods of mangroves. The interior is more elevated, and is a vast plain, extending from the shore about 150 feet above the sea-level, but towards the southern side there are a few small elevations, which probably rise to 200 feet. The island is well clothed with wood, and presents one of the most elevated, picturesque, and fertile districts. The ground is covered with small shining masses of ironstone having a metallic lustre as if they had been ejected from a furnace. The sloping sides are less stony, and the flat ground is generally quite free from stone. Streams of water are scarce, but the swamp water is generally drinkable, and by skimming wells a constant supply of excellent water is obtained. The swamps are generally full of long grass and reeds, intermixed with small trees. Narrow gullies cut up with a kind of cane or reed (Flagellaria indica, Linn.) lead into these swamps.

The soil of the island is of inferior quality, partaking of the character of the ironstone which is generally spread over it. The soil is stony, and that is to a greater extent than is commonly supposed. The close to the shore the country is very rocky, and the soil is light and sandy, intermixed with sand and gravel. Bordering on the swamps it is richer and more productive, and it is supposed that some of the flat soil situated are capable of producing rice. The vegetation is very luxuriant, and during the whole year there is plenty of grass for cattle. The timber is in general of good quality, and although trees which are small in the stem predominate, there are many of considerable dimensions, and are useful for building fences, hut building, fencing, and to agricultural purposes. The average number of trees to an acre is about one hundred and twenty, but in some places they amount to one hundred and eighty. Among these forest-trees several species of eucalyptus are most abundant. The cabbage-tree is common. Ginger grows wild.

The most common quadrupeds are kangaroos, opossums, bandicoots, native dogs, a small brown rat, and a species of squirrel. The Termite bat or flying fox is very numerous. The birds are mostly distinguished by their beautiful plumage, especially some species of cockatoos and parrots. There are also several varieties of king-fisher, among them the gigantic king-fisher (Dacelo gigas), swamp pheasants, quails, currawongs, wild ducks, sand larks, wild geese, several kinds of cranes, and a wild fowl of the gallinaceous order of considerable size. Many beautiful small birds are very abundant. The length of many of them is about twelve in length; some of them are venomous. There is also a great variety of lizards of beautiful colours: the largest are the frilled iguanas (Chlamydosaurus Kingii), and the common iguanas (Iguana delicatissima). A large snake found in Apley Strait, and turtles are found at some places on the coast. The most destructive of the numerous insects are the weevils.

The number of natives is rather large, considering that they lead a wandering life, and during the dry season live on kangaroos, opossums, bandicoots, iguanas, and lizards; and during the wet season live on fish, turtles, crabs, and other shellfish; and live mostly on a tree called the sago-palm. They are evidently of the same stock as the natives of Australia, but they are more athletic, active, and enterprising. Their language is said to be so far different, that a native of New South Wales could not understand the word of what they said. In the construction of their canoes, spears, and waddies, they show much ingenuity, although the workmanship is rough from want of tools. Their canoes, water-buckets, and other receptacles are made of bark or wood, with strips of split cane. They are extremely deficient of strangers, and it was found impossible to enter into any friendly intercourse with them during the four years that the British settlement has been on the island, which is about 45 miles from the colony, and it was ascertained that the soil was far from being fertile, and the climate very debilitating to Europeans, although not decidedly unhealthy. These combined circumstances led to the abandonment of the settlement in 1828, but in 1837 a new one was established in Port Essington on Coburg Peninsula, a place which is visited by the inhabitants of Macassar and other islands, to fish for trepang.

MEMLING, Hans, or JAN, until recently more commonly called Memling, and sometimes Memmleinck, was born at Bruges, about 1445. The initial letter of the name on his pictures is the very same letter as the initial of Maria on a coin of Mary of Burgundy, and in many other names commencing with M, documents of the period. It is the capital M of that time, though modified from M, as in our H with an additional short stroke in the middle, reaching from the under side of the cross line to the bottom of the letter; or somewhat like a small Roman m, the two outside strokes being doubled. On the other hand, his peculiar letter however occurs in two instances as an H also; the question is therefore not absolutely decided. Because a Hans Memling or Memling is mentioned in a German MS., it does not follow that the person with that name is the same as our Hanemling. It is not improbable that Memling's residence in Bruges prove that he was a Fleming, as he may have been attracted there by the fame of Van Eyck. He was born at Bruges, and for that reason Wyngaerde notices a German painter of the name of Hans who lived at
Bruges, and he addled very profusely to Memling. Vasaari also apparently alludes to Memling when he speaks of Ause (Anse) of Bruges. The dates of Memling’s pictures range, according to the printed accounts, between 1450 and 1499. The earliest of these pictures is a painting at the town hall of Aragon, wife of Philip of Burgundy; this picture is mentioned in the anonymous Journal published by Morelli in 1800—a Notizia di Operé di Deseo nella prima Meta del Secolo X V (ed. di N. Morelli, 1800). Crema, and Venetia, scritta da un Anonimo di quel Tempo,’ in which the picture is called Maselino or Memlingo. If this date is correct, Memling must have been born before 1449. His earliest work was probably the Adoration of the Magi at the Convent of St. Catherine in Bruges. The date 1499 is found on a small picture in the possession of M. van Erbom at Utrecht; it is also the year in which he finished some paintings for the Carthusian convent of Miraflores near Burgos in Spain, in which he is said to have died not long afterwards: the account is given by Ponc, in his ‘Viaje de España.’ This convent was destroyed by the French in 1812. Memling appears to have lived some years in Spain; he is supposed to be the Jan Flamenco of Flanders who was at Miraflores between 1496 and 1499, and perhaps later. He probably also visited Italy and Germany, and certainly Cologne; and he is said to have served Charles the Bold at Dijon. This early period of Memling’s life is not marked by any particular achievements; his work is neither rich nor variegated, nor picturesque. The story is, that he was at the battles of Granson and Morat, in 1476; and in the beginning of 1477 he was admitted, ill from wounds and destitute, into the Hospital of St. John at Bruges, where he was received on the foundation, none but inhabitants of Bruges or Maldeghem could be admitted. It was during his residence in this hospital that he painted the beautiful pictures which still adorn that hospital. He was named ‘Prophet of the Bruges of the French,’ a title which was given him from his name among the first of the painters of the fifteenth century. The principal work by Memling in this hospital is the history, in minute figures, of St. Ursula and her companions, executed in oil in many compartments, upon a relic case of a gothic design, known as La Chaise de S. Urasule. This chaise, or shrine, has been made the subject of a special work by Baron van Eeghen, and inserted into the British Museum, ‘d’apres le Legende, et les Peintures d’Hemling,’ Ghent, 1818. The paintings have been drawn in lithography by M.M. Manche and Ghemard. Memling painted also during his stay in this hospital the splendid large altarpiece of the Marriage of St. Catherine; both of which are still there. The Marriage of St. Catherine, in which the figures are much larger than is usual in the case of Memling’s works, was painted in 1479, and is one of the most brilliant pictures of the fifteenth century. It is in three compartments, a centre and two revolving wings. In the centre is the marriage of St. Catherine, and in the background are painted episodes illustrating the lives and martyrdoms of the attendant saints and of St. Catherine herself. The left wing is the beheading of John the Baptist; the right represents the marriage of the Barberesses of Kastoria in Thessaly. The painting of Patmos: the last is a remarkably comprehensive composition. On the exterior of the left wing are two Hospital Brothers, the Apostle James, and St. Anthony of Padua; on the right exterior are two of the Hospital Sisters, with saints Agnes and Clara. There is an inscription on this work, but as it has been renewed, it cannot be taken as an authority in a difference respecting the signification of letters: it is however variously treated. There are three other pictures by Memling in this hospital—a Descent from the Cross, upon wood, with two wings; the Madonna and Child, with a portrait of Martin van Nieuwenhoven, burgomaster of Bruges. In 1499, on the north side of this picture, is a name inscribed in 1487; and a female, inscribed ‘Sibylla Samthena quæ et Persa per anc. ante Christ nat. 2040.’ There are other works by this painter in the Academy of Arts, and in other buildings of Bruges. There is, or was in 1832, a small portrait of a young man in the costume of the hospital brothers of St. John, in the collection of Mr. Aders in London, which is said to be that of Memling himself, but the date on the picture is 1462, fifteen years before Memling is supposed to have entered that hospital, and the history of the picture is not positively known. Passenart has engraved it in his ‘Bouw- en Kunstenaar der Zuiden und Belgen.’ Dr. Waagen does not mention it. Another very interesting work, by Memling, is the collection of Mr. Aders, the travelling altar-piece or altar of the Emperor Charles V., which was preserved in the cathedral of Bur-
undyng name. Few of Memmi's works now remain, and those few are performed degre in 1898; he was the principal men*
the frescoes of the chapter of the chapel degli Spagnuoli at
Florence, painted in 1332; they consist of stories from the
lives of Christ, San Domenico, Santa Peter Martyr, and part
of the Legend of the Donor. The fame of the Donor
was never higher.
In one of the last works are the reputed heads of Petrarch and
Laura, but this story, as Lanzi says, is a mere fable, for
Memmi did not paint Laura until four years after the com-
pletion of these works, as is proved by the inscription
given by Avignon. [GADDI, TADDEO, F. C. S.] There are also
some stories by Memmi, from the life of San Ranieri, in the
Campo Santo a Pisa; they are engraved in Lainosi's 'Il Vittore
del Campo, a Pisa.'
Simone painted also in miniature. There is a MS. of Vir-
gili, with the commentary of Servius, now in the Ambrosian
Library at Milan, but formerly in the possession of Petrarch,
which is preceded by a miniature of Virgil seated with his
pen in his hand, invoking the poetic muse; before him is
Zeus in armour, with his sword, representing the Aeneid;
there is another, a shepherd and a tithe, representing
the burning of the Colosseum; another of Zeus, and Servius is also there,
drawing a fine veil to himself, as symbolical of the elucidation
of his commentary. This design, supposed to have been
made at the instance of Petrarch, is inscribed with the
following couplet:

- "Vestis Virgilii quae tellus carmine fixata,
Susa dedit Simoni digito quae tuta plaxit."

Memmi died in Avignon in 1444; according to the necro-
logy of the Dominicans at Siena, aged sixty, according to
Vasari, but much older according to Della Valle and some other
authorities.

Notwithstanding Vasari's encomium upon the style of
Memmi, which he said was worthy of one of the moderns,
his remaining works are not at all beyond his age, and
he was surpassed by the two Gaddi: his design is meagre and
ugly. Of his portrait of Laura nothing whatever is known. The
reputed head of Laura above mentioned is engraved in
D'Agincourt's 'Histoire de l'Art par les Monuments,' Print.
pl. exzii. 2, and in Cicognara's 'Storia della Scultura,' i.
pl. 48. Cicognara has disputed the authenticity of this and
some other reputed portraits of Petrarch and Laura, at con-
siderable length in the third volume of his History. The
only authentic portrait of Laura extant, of that age, appears
to be a miniature in a MS. in the Bibliotheca Laurentiana at
Florence, which however may have been copied from the
original work by Memmi: there is an outline of this also in
Cicognara's work, i. pl. 42.

Vasari gives the following as the inscription on Simone's
tomb, but he does not say where: — Simoni Memmiu pic-
torum omnium octavi aetas celeberrimo. Visit ann. LX.
mecl. Mauro, the chief excelsior in his art. There are a few of
his works still extant. He was living in 1361.

(Vasari, 'Vite de' Pintori,' &c., and the notes to Schom's
German translation of Vasari; Della Valle, 'Lettere Scelte';
Lanzi, 'Storia Pittorica,' &c.; Rumohr, 'Italienische Forschungen.'

MEMMI DI MARTINO. [Simone, P. C. S.] MENANDER. ARRIUS, a Roman juris, of the time of
Severus and Caracalla. The work of his mentioned in the
Florentine Index is four books on Militaria. There are
six excerpts from Menander in the Digest.

MERCEN. [Simon P. C.] MERCER, LOUIS SEBASTIEN, a prolific writer on men
and manners, politics, science, the drama, literary crit-
icism, and many other subjects. The greater part of his
works are sunk in oblivion, but several of them still deserve
and obtain opinion.
He was born at Paris on the 5th of June, 1740. He was for some years professor of rhetoric in
the college of Bourdeaux. The works for which he chiefly
deserved attention at the present day are his attacks on the
manners and morality of his age. The first of these appeared
in 1771, with the title: 'L'Am 2440; Rêve, s'il en fut jamais.'
In 1781 he commenced the publication of the 'Tableau de Par-
is,' in which he preserved the attention of the French
authorship of this book which, by its bitter remarks on all
the social institutions of France, was sure to provoke their wrath,
he found it prudent to retire to Switzerland, where he com-
pleted this remarkable work. Without holding with its
author that the 'Tableau de Paris' produced the French Re-
volution, there is no doubt that it did much to open the eyes of
mankind to the immoral and corrupt state of the social
system of the French capital, and the inapplicability of the
great national institutions of the country to supply their proper
end. It is said that it was read by the Duke of Orleans,
with an animated, descriptive, and biting pen. He occasion-
appealed to a high sense of morality, but his chief power
lay in showing his readers the bad taste and the folly of the
prevailing habits of the day. Wherever he had to depict
honest industry struggling against false social laws, or the
remains of pristine simplicity holding out against the inroads
of corrupting manners, his tone is dignified and feeling. In
the latter case he ably and ingeniously commented on the
artificial and vicious tastes of the leaders of fashion, of the
triumph over the free expression of opinion, he overwhelm-
his sarcastic ridicule. The work is a curious anatomy of
Parisian society, and exposes many evils incident to large cities,
of which the lapse of sixty years has not entirely enabled us
to find the remedy. The sanitary regulations which have
lately so much occupied the attention of society, and other
means of social organization, are intended to supply deficien-
cies which Mercier points out in his own peculiar fashion:
whether he could have devised remedies for the defects he
then discovered and questioned. He was an author burdened
with paradoxes. In 1801 he published 'Néologie, ou Vocabulaire
de Mots nouveaux, à renouveler, ou pris dans des Acceptions
nouvelles,' a work in which he announced such propositions
as: 'Les mots 'parfaits' et 'parfaits' sont des mots en pro-
vice de la langue,' according to the chief ornaments of French literature; seeming, wherever
public opinion had unequivocally declared itself, to find that
he had to perform the function of reversing the judgment.
In philosophy he was equally paradoxical, and contended
against the best-established truths in physical science.
From these peculiarities his attacks on the social morality of
his age have been received as chance blows struck in a right
quarter by a man of extraordinary originality. The chief
virtue of his 'Tableau' has thus frequently been looked on as no more
the result of just observation than the censorious remarks of
a universal grouch, who, living in a brothel or a gambling-
house, should condemn the principles and customs by which he was surrounded. But Mercier deserves
a better appreciation, and none can attentively read his
works without seeing that they proceed not only from a con-
ception of what is wrong, but a sense of what is right. A
list of his works would be much longer than the present
article. He passed a life of cheerful vivacity, surrounded by
friends who seem not to have been the more anxious to
please him that he perpetually displayed with singular simplicity his sub-
lime self-conceit. He died on the 25th of April, 1814.

MERCURIUS, a genus of plants belonging to the na-

MERCURY, DEPRESSION OF. [Depression of
Merician, Matthew, a very distinguished German
portrait painter, who received the authorities to
name the same name, who was born at Basel, in 1693, where the son
was born in 1821. He was the pupil of Sandrart, who was
much attached to him; he studied also after Vandyck in Lon-

don; became acquainted with Le Sueur and Vernet in Paris,
and studied underSucchi and Carlo Marsatti at Rome. From about 1834 to 1837 he was in the main chamber of the Vatican, engaged in correcting his father's book and print business, at Frankfort on the Main, but he did not give up his own profession. He painted the Emperor Leopold I. on horseback, and many other German and foreign sovereigns. His works are amongst his most finished pieces, and engraved a few plates, which are marked M. Merivale, junior. He died at Frankfort, in 1867.

Matthew's sister Maria Silvya Merian was an eminent in società painter. She died at Amsterdam in 1777, aged seventy. [Sander, Teutsche Academie, &c.; Fiorillo, Geschichte der Zeichnenden Künste, &c.; Drury, Life of Herman, J. Rees, and J. G. C., &c.;] Thos. HERMAN, was born at Exeter in 1779, in which neighbourhood his father, John Merivale, Esq., resided, and was possessed of some landed property: his grandfather, the Rev. Samuel Merivale, was a Presbyterian minister at Exeter, and tutor at the dissenting theological academy there. Mr. Merivale entered St. John's College, Cambridge, in 1797, but took no degree, in consequence of the impediment of his dissenting persuasion, although at a later period he joined the Church of England. He married Louisa, daughter of the Rev. Dr. Drury, head master of Harrow School; she was called to the bar in 1805, and practised in the Court of Chancery. He published three volumes of Chancery Reports from 1811, of 700 pages, decided by Lord Eldon and Sir William Grant. In 1825 he was a member of the committee for inquiring into the state of the Court of Chancery, which was appointed in consequence of the financial crisis of 1825, when the Court was near bankruptcy, and wrote 'A Letter on the Chancery Commission' in 1827, as well as some other pamphlets on law reform. He became a commissioner of bankruptcy on the then newly organised system in 1831; and continued to hold that office till his death in April, 1844. From his early youth Mr. Merivale was addicted to literary and antiquarian pursuits, especially to the study of Italian and, in his later years, of German literature. He contributed a large proportion of the translations contained in the 'Collections from the Greek Anthology,' published in 1813 under the editorship of the Rev. Robert Bland; of which Mr. Merivale brought out a second edition, enlarged, in 1833. In 1814 appeared his poem of 'Orlando; in Roncesvalles,' a tale in the ottawa rima, being chiefly a free abridgment of part of the 'Morgante Maggiore.' In 1841 Mr. Merivale published two volumes of 'Poems, original and translated,' comprising most of his earlier pieces; and in 1844, shortly before his death, a volume of translations of the 'Minor Poems of Schiller, of the second and third periods, with a few of those of earlier date.' This perhaps was the most successful of his productions. It is an essay towards the rendering the lyrical pieces of the German poet in the same, or nearly the same, metre with the originals, and with as much of the slavish respect for the tone and character of the metaphysical or subjective poems of Schiller's later period—those which it is the most difficult to bend to this species of treatment—the Gods of Greece, the Feast of Eleusis, the Passion, and the Road of Life—those are among the best executed parts of the work. Mr. Merivale was an extensive contributor to literary reviews, but none of his prose essays on these subjects are published in a separate form.

MERSERISM. [Animal Magnetism, P. C. S.] MESOLO'NGHI or MESSOLON'GH, perhaps the antient Olenas, 'Oλένας, in Aetolia, a small town in Greece, lies on the northern side of the Gulf of Patras, near its entrance, and right opposite Cape Kologoria or Papa in the Morea. It became remarkable during the last Greek insurrection against the Turks, as is stated in the Life of Bozarias in this Dictionary; by an union of the inhabitants of the town, and of the forces of it by Ibrahim Pasha, the commander in chief of the besiegers. The heroic resistance of the Greek garrison, and their ultimate fate, made the name of Messolonghi popular with the Greek nation and in the English language. Messolonghi is built on the edge of a marshy plain, bounded on the north by the high ridge of Zygog, the antient Areynthos, which is protected towards the sea by a lagune extending about ten miles along the coast and five in breadth, and hence perhaps the name of the town, which seems to be a contraction of the Italian (Venetian) words 'mezzo' and 'laguna.' With the exception of a few very tortuous channels, the lagune is impassable for any craft drawing more water than the 'nonoxyla,' or small boats of the inhabitants. The main channel in the south is commanded by the mud-bank of Vassiladi, on which the Greeks had built a small fort and some houses in the north, by the town of Batoas and Anatoliko. At the time of the outbreak of the Greek revolution the town contained several thousand inhabitants, who derived wealth from their extensive fisheries. The fortifications were in such a condition that Bayle proposed to the Greeks to strengthen the place by additional works; but the Turks left them only time to add a rampart of earth faced with stones, and a ditch, which surrounded the town on the land side, and obstructed the progress of the 25th to the Turkish commander in Northern Greece, in the beginning of 1825, many Greek palkiers and others flocked to Messolonghi with their families, so that the garrison was increased to about 5000 fighting men. Their attacks were repulsed by the veteran Nothi-Bozarios, Sornari, Mitcho-Koutouyan, Liaketas, Lambro-Vieks, George Rizzo, Niketas, Takos, Makry, and others; and the body of officers was increased by many foreign volunteers, mostly German noblemen and gentlemen. On the 25th of April, 1825, Reshid Pasha appeared in sight of the town, with an army of 20,000 men and a numerous battering train, to which the besiegers could only oppose forty-eight bad iron guns of calibre varying from 4 dif 48-pounders, two brass 10-inch mortars, one howitzer of 5 inches, and one mountain howitzer of 41 inches. The Turks made the first trench on the 5th of May, and on the night of the 11th a terrible storm came on, and was accompanied by a hurricane, and the 27th and 28th, were, from the 12th to the 15th, and from the 18th to the 20th, a perfect gale, and the topstee of the buildings, and the stormings now succeeded each other during two months, but the fire was well answered from the rampart, and the Greeks made frequent sorties, in which they always defeated the enemy. The Greeks were able to throw up a line of works specially on the 2nd of July. The Hydriotic fleet stationed at the entrance of the lagune, there was no lack of ammunition and provisions in the town, till, on the 3rd of May, the Turkish fleet appeared off the place, and, after having obliged the Hydriot to avoid a certain defeat by a hasty retreat, landed a strong body of Turks, under Husein Bei. On the 28th of July, the 2nd of August, and in the night of the 3rd, the fortress was furiously assaulted, and a terrible cannonade carried destruction among the houses and their inhabitants; but the Greeks stood their ground, and were excited to hope of certain victory when, a few days afterwards, the Turkish fleet under Mauilis and Sakhtouri came in sight, and after a severe conflict defeated and dispersed the Turkish fleet. The maritime blockade was now at an end, and in the beginning of September the garrison was still 4000 strong, with an additional population of 10,000 women, children, aged or infirm men. Reshid Pasha, however, was far from being discouraged, and resolved upon still more vigorous attacks; but Sultan Mahmud, who was then possessed upon the importance of Messolonghi, gave orders to Ibrahim Pasha, who commanded in the Morea, to take the chief command, while Reshid Pasha was to act as his first lieutenant.

The Egyptians then moved northward, and towards the end of November the combined fleet of Turkey, Egypt, and Barbary, drove the Greek fleet from the lagune, and kept a strict watch over its entrance. During the whole of the months of October and December the Turkish fleet passed without the Turks making an assault. In the first week of January, 1826, Ibrahim Pasha appeared in the Turkish camp with 14,000 Egyptians and an ample supply of provisions and ammunition. During the first fortnight he was nearly inactive, hoping that a strict blockade would compel the inhabitants to surrender for want of food, nothing having been introduced into the town since the end of November. Although the inhabitants were on the verge of starvation they would not capitulate, and continued their deadly sorties, when at last, Ibrahim, after having taken the islands of Poro and Anatoliko, made the town a heap of ruins by the destruction of the whole town and eighteen churches, character—are among the best executed parts of the work. Mr. Merivale was an extensive contributor to literary reviews, but none of his prose essays on these subjects are published in a separate form.
driven back within the fortress, or massacre prisoners while in the midst of the enemy's army. Their ammunition and food being completely exhausted, so that even cats and rats were devoured, the morrow, the garrison resolved to cut their way through the enemy lines and retreat into the neighboring mountains. According to the best authorities the population consisted in the month of April, of about 400000 persons, fighting men and women, almost all being bound upon the besiegers and cut a way for 6000 women and children, while the retreat was to be covered by a thousand men, and the fortress guarded by a few devoted warriors who were to burn the city and sacrifice their lives to their brethren. The 22nd of April was the day on which the Greeks were to try their last chance. But the plan was betrayed to Ibrāhim Pasha by a Hungarian deserter only a few hours before its execution, and the inhabitants of Mosoulah appeared outside their shattered stronghold, they were suddenly surrounded by the main body of the Egyptians. A dreadful conflict ensued. Five hundred men were cut down by the infuriated besiegers; 1800 persons, of whom 200 females, were females, escaped, of whom, however, 600 were starved to death in the mountains; and Ibrāhim boasted of having taken prisoners 5000 soldiers, and from 3000 to 4000 women and children, and many of the captives were afterwards ransomed through the exertions of the Philhellene societies in Europe. Notghi-Bozari and Mitche-Koutanyi, though both upwards of seventy, escaped safety. Among the slain were Joseph Butsh of the Papadias, the General Stournas, Sadiunas, and many other Greeks of note. Among the German, Baron von Riedesel and Lieutenant Rosser were killed during the siege; Colonels Dittmann and Perrot, Captains Mullow and Stilzelberg, Lieutenants Klemp and Schipan, and several other gentlemen fell in the sortie. With them remained on the battlefield Dr. Meyer, another German, who was the editor of a German periodical. He said that he was equally partition between his pen and his sword: "his wife and children were dragged into slavery. 'History will do us justice,"' wrote the gallant doctor, a few days previous to the last sortie, to a friend--and postscript went over our master, My the relation I have drawn up of the siege survive me.' This relation was unfortunately lost.

Thus fell Mosoulagh after a siege of twelve months and after 100000 shot and shells had been exchanged between the besieged and the besiegers. Its melancholy fate excited the sympathy of all Europe, and there is scarcely a modem language in which poems were not written on the heroes of Mosoulagh.

(Gordon, History of the Greek Revolution.)

MESOPOTAMIA (from the Greek μεσός, 'middle,' and ὅπως, 'a country between,' is a term which was used by the Greek and Roman geographers (Strabo, and others) to comprehend all the countries which lie between the rivers Euphrates and Tigris, and it is still in use. The Arabians call this country by the names of Al-Isirah, or the island. As Mesopotamia is not a political division, geographers do not agree as to the extent of the countries to be comprehended under this name. Some consider it to be the central countries, or those lying between the 38° N. lat. and the Chalde or Median Wall (34° N. lat.), whilst others extend it northward to 40° N. lat., or the sources of the Euphrates, and southward to 30°, where the Tigris and Euphrates unite. We shall here give a description of the countries included between the parallels of 40° and 30° N. lat.

When a traveller departing from Trebizond or Rizeh, on the northern coast of the Black Sea, directs his course southward, he passes over several mountain ridges running east and west, and is soon aware that the country rises rapidly. About seventy miles from the sea he finds himself on the most eastern point of an island which is united to the continent of Asia from east to west, and which in ancient times went by the name of the Taurus and Antitaurus. This northern chain is traversed in its length by the parallel of 40° N. lat. but a little south of it, and the higher lands are always covered with snow, and many summits are 10000 feet above the sea-level. From these mountains the view ranges so far as the eye can reach, to several elevated table-land, that of the Euphrates and Murad, which is bounded by the parallel of 38° and 36° N. lat. in the East, and by the parallel of 30° N. lat. in the West, and whose surface varies from 3000 to 6000 feet above the sea-level, but several of the mountain masses attain 10000 feet. On the other hand, it varies between 89° and 90° N. lat., and the kline region of Mesopotamia, or the alluvial region of the Taurus. The country here sinks gradually from 2500 feet to 1000 feet and less above the sea-level. It is succeeded on the south by the great desert plain of Mesopotamia, which encircles the whole Persian gulf between the two rivers, or between 36° 30' and 34° N. lat. This region is as low as the Arabian plain of Babylon by the Chalde or Median Wall, which begins on the banks of the Tigris, near 34° N. lat., and it terminates between 36° 30' and 36° N. lat. This wall and the lower course of the two rivers up to their junction, enclose the fourth region, the plain of Babylonia, or of Irak Arabi.

1. The table-land of the Frat or Murad lies between 40° and 38° N. lat., and between 38° and 44° E. lon. In width from north to south it extends about 100 miles, and in length from east to west about 250 miles. This gives an area of 5000 square miles, or 10000 square kilometers, It is the most elevated portion of the high grounds by which the table-lands of Asia Minor are connected with the great table-land of Iran or Persia.

The elevation of this table-land varies greatly. The highest part is on the north-east corner, where the lowest part of the country is about 6000 feet above the sea-level. Hence it descends rather rapidly along the banks of the Frat or Karasu, for Erzerum is nearly 4600 feet, and Erzincan probably not more than 4000 feet above the sea-level; where the Frat meets the Murad the elevation is less than 3000 feet. The descent along the Murad river is somewhat less rapid, as the town of Basrah is only 1500 feet above the sea; at Palu the level of the river is 2819 feet above the sea.

This table-land has a very unequal surface, but the inequalities constitute large masses. The Kop Dagh, which forms the southern border of the Murad, rises in the north to a height of 10000 feet. Its northern face, or that which looks towards the Black Sea, is well wooded, but on its southern declivity there are no forests. Another mountain-chain, called the Khasran Dagh, runs in a north-west direction, and the place where the Euphrates makes its great bend opposite the town of Malatyah. Towards the east this range rises from 7000 to 8000 feet above the sea-level, for the mountain-passes which traverse it are from 6000 to 7000 feet high; but it appears to be lower towards the west; and that portion of it which surrounds the source of the Tigris is only 5000 feet high. This appears also to be the general elevation of this mountain-mass where it comes close to the bed of the Euphrates, where this river forms its three hundred cataracts between Isgol or Fisgolu and Gergor. No mountain-range over two thousand feet is to be seen on the east of this table-land, a level between the Murad and Araxes rivers. But west of the source of the Murad the Ala Dagh rises above the snow-line, and it appears to be an isolated mass. Much farther to the west, in the north-west of the table-land, are two mountain-passes, of which the eastern is called Bingol Tagh, and the western Dukj Tagh. The declivities of the last-mentioned range are so great, that the banks of the Frat above its confluence with the Murad. The two mountain-passes are probably separated from each other by a wide depression, and both rise above the snow-line.

Those parts of the region which are always covered with snow do not appear to cover a considerable space, but from their declivities mountain-streams descend, which are always copiously supplied with water. This circumstance, united to the great extent of snow, which during the winter months, makes this table-land one of the best-watered regions in Asia; and the whole surface, with the exception of the most elevated parts, may be turned to useful purposes. The largest part of this table-land is intended for cattle and sheep, but the higher parts are covered with wood, especially as sheep-walks. The number of sheep must indeed be great if there is no exaggeration in the statement that one million and a half of sheep are sent annually from this region to Istanbul and Thrace for the market. They arrive at the place of their destination after a journey of eighteen months, and one-third of them are said to perish on the road. Large rocks are also sent to Durack, Arslan, Aleypo, and Damascas, and even as far as Egypt on the...
The surrounding country is very fertile, and considered the most populous portion of the table-land.

II. The Hilly Region of Mesopotamia, or the Chelva region of Mount Taurus, lies to the south of the Kzarzan Tagh, from which it extends southward along the left bank of the Murad—er-en-road which runs from Bir-ed-jik on the Euphrates, to Mosul on the Tigris, past Urfa, or Orfa, Marvun, and Nisibin. This caravanserai lies along the base of the Hilly Region. This region lies between the parallels of 37° and 38° N., and 43° E. long., and extends about a hundred miles from north to south, and two hundred and fifty from east to west, so that its area may be roughly estimated at 25,000 square miles, or equal in extent to the table-land of the Frat and Murad.

This country may be considered a continuation of the table-land of the Frat and Murad, or rather as a southern terrace of it. The northern districts are about 6500 feet above the sea-level, from which elevation it gradually descends to about 1000 feet, or somewhat more, where it is contiguous to the Great Desert Plain of Mesopotamia along the caravanserai. Only the most eastern part of this road between Tell Ramalan and Mosul is at a lower level, and runs through the Great Desert Plain.

The highest part of this region is that which is on the west borders on the banks of the Euphrates between Issghin and Gergur, where the river forms its three hundred cataracts, and on the east on the upper course of the Tigris between its source and the town of Diyarbekr, which is nearly 5000 feet above the sea; the source of the Tigris are only about 2000 feet.

The level of the surface of the Euphrates near the confluence of the Frat and Murad is upwards of 2600 feet, and at Gerber it is about 2800 feet, while the highest places are masses which rise abruptly from the water's edge, at many places perpendicularly, generally attain near the river an elevation of between 3000 and 8000 feet, and a greater height at some distance from it. The highest portion of this tract must therefore be more than 5000 feet, and it may be 6000 feet. It does not, however, appear that any portion of it rises so far above the general level of the masses as to form conspicuous summits.

This tract is little known. In all depressions there are small villages surrounded by walnut-trees, and a little cultivation, but the inhabitants derive their subsistence chiefly from their cattle and sheep.

East of this mountain tract lies the Plain of Diyarbekr, or of the Upper Tigris, which extends from some miles west of the town of Diyarbekr to some distance east of the town of Sert, about 120 miles in length, and from the Kzarzan Tagh on the north to the Karaja Dagh on the south, about 40 to 50 miles; on the east it is shut up by the most elevated part of the mountains of Kurdistan. It is a most valuable part of Western Asia, especially that portion of it which lies on the land towards the Persian Gulf, where the climate is very healthy and pleasant for the cultivation of the Kzarzan Tagh.

The declivity of this range is not so steep as that which descends to the banks of the Murad, and the slopes are in many places intersected by terraces from two to three miles in width. These terraces are cultivated by the inhabitants of the Murad Massa, but they are cut by wide valleys, which descend from the summit of the range to the plain below, and in which the waters collected on the top, which for many months of the year is covered with snow, find their way to the lower country. Rich crops of wheat and barley are obtained everywhere, and in some places, where irrigation can be practised, rice is grown. The sides of the hills which enclose the valleys, and the valleys themselves, are partly covered with orchards and plantations, consisting of walnuts, figs, vines, pomegranates, mulberries, and the fruit-trees of Northern Europe. In some places cotton, melons, and platanus are grown to some extent.

The deep valleys on the mountains are thickly covered with woods, in which two kinds of oak abound, one of which yields gallnuts, and the other a kind of manna, which is much used in the country. In some parts the steep declivities of the hills have been terraced into very good arable land, which is planted with fruit-trees and irrigated.

The Plain of Diyarbekr itself is less fertile, and not cultivated with such care as these valleys. Its surface may at the lower part be about 1700 to 1800 feet above the sea-level. There are many terraces which are quite level, and others have an undulating surface; a few are hilly. The rivers, especially the Tigris, run along the level of the country, which renders it difficult and expensive to use the waters for irrigation, and as the summers are hot and dry, only those tracts can be cultivated which have a better soil. The others are only used as pasture-ground.
during the wet season, and until the grass is dried up by the heat. In some parts the surface is bare of mould and consists of naked rocks. There are no trees on this plain except mulberry and poplar, which are planted in some places. Corn and barley are grown, and some cotton, and also maize. In the vicinity of the town of Diarbekr cultivation is carried on with more vigour: flax is also grown.

At a distance of some miles south of the Tigris, where the river runs from west to east, the plain is bordered by rocky masses, which rise with rather a steep ascent to 2000 feet above the general level of the plain. Though they appear for a distance like a line of mountain, they are really composed only of the outcrop of a table-land which occupies the whole country between the Euphrates and Tigris, north of 37° N. lat. and compiles the Tigris to run eastward, from the Euphrates west and north of 38° N. lat. These two rivers are hardly thirty miles apart; but sixty miles farther south, between Rumkalah on the Euphrates and Jezirah Ibn Omar on the Tigris, they are more than two hundred and twenty miles from each other. The highest part of this table-land runs from north-west to south-east, beginning at no great distance north-east of the town of Severock and terminating with the hill on which the town of Mandrin is built. This ridge it appears is properly called Ras el Dagi. This region has no watercourses, though a considerable quantity of snow appears to fall during the winter months. This must chiefly be attributed to the limestone, of which the whole country is composed, and which quickly absorbs all the water. Where this is the case the country generally presents bare rocks, or only a very scanty vegetation during the wet season. But the plains composed of alluvial deposits are covered with grass, and the tracts which are crossed with basaltic strata are covered with grass, and the tracts which are crossed with basaltic strata are covered

The whole country is imperfectly known, especially the portion contiguous to the Tigris, which has been visited by European travellers only in the vicinity of the river. Where the bed of the river is narrowed by the mountain-masses advancing to the water's edge on the east from the mountains of Kurdistan, and on the west by the Karke mountains, the surface of the table-land is nowhere broken by valleys and ridges, interspersed here and there with elevated plains. The valleys are well cultivated, and produce wheat, rice, cotton, tobacco, cucumbers, and melons; some of them have good vineyards. The ridges are well covered with oak, pine, holly, elm, and several bushes. The plains afford good pasture-grounds, and are also partly cultivated. Farther inland the country appears to be more uneven, as the inhabitants are able to defend the Turkish government and to maintain their independence; but according to the accounts of the natives there are many fertile valleys in it. If their accounts deserve credit, the eastern districts are much more fertile than the western, where the want of moisture in the summer is so great that nearly the whole is a desert, with the exception of some depressions, whose surface is formed of basaltic strata, and where a few villages occur with some cultivation. In approaching the banks of the Euphrates the portion between the rivers, the Euphrates and the Tigris, is cultivated in several of their confluentes. There are also several kinds of turtles, snakes, and lizards.

The Hilly Region of Mesopotamia constitutes the pashalik of Diarbekr; but the most south-eastern districts are sometimes placed under the pasha of Mosul. The most remarkable places are situated either in the Plain of Diarbekr or along the mountain road between Bir-chek and Mosul. In the Plain of Diarbekr are Diarbekr. [Diarbekr, P. C., vol. viii., p. 477.]

North of Diarbekr, on the southern declivity of the Khraran Tagh, are very rich mines of copper, in whose vicinity are two towns, one of which is called Arghana (or Arguna) Maaden, and the other Maaden Kapur. Arghana Maaden is built round the summit of a high hill, 3887 feet above the level of the river, the edge of the mass is split and indented, and numerous small valleys are cut through the high ridges. The country is not cultivated, but the largest part of the town is covered with orchards, consisting of olives, pomegranates, mulberries, pears, peaches, and quinces; all of these have also excellent vine plantations. In some parts cotton is cultivated. The country through which the caravan-road between Bir-chek and Mosul runs, has great variety of surface and soil. Between Bir-chek and Urfa it is hilly, and contains many cultivated tracts. Farther east, as far as Mandrin, cultivated and wooded tracts, mostly situated in depressions, or valleys alternate with plains, which in some cases afford pasture, and in others submerge the country. This tract of country the ridges running south and north rise to high hills, generally of a conical shape. These ridges continue to Nisibin, but are less frequent. Between them run some watercourses, which are crossed by basaltic strata, and occasional desert country, which lies farther south. East of Nisibin cultivation ceases; but as in this part there are numerous watercourses, the adjacent country has pasture even during the summer months. After El Rasouh a hill, called el Mesopotamia, enters the Hilly Region of Mesopotamia and enters the Desert. This region has a more temperate climate than the table-land of the Frat and Murad, on account of its less elevation, the mountains surrounding it on the east, north, west, and its more southern situation. But the climate is much colder than that of Europe in the same parallel, because it lies much farther from the sea, and does not receive the warm western winds prevalent on the Mediterranean, as the elevated chain of Mount Lebanon and Anti-Lebanon prevents them penetrating so far eastward. The thermometer has been observed to descend as low as 12° of Fahrenheit. In January and February a great quantity of snow falls. The spring hardy is preceded by a heavy rain in March, which is generally followed by which hardly any rain falls to the end of October, or the commencement of November. The thermometer rises to 56°, and all grass and minor vegetation dries up. Pasture is then only found on the lower part of the country, which is why in many places of the table-land. Nature becomes reinvigorated in the month of November, when the Nile clouds appear, and the waters proceed from Mount Lebanon eastward, and bring to the table-land very heavy rains, which about the beginning of the year are changed into snow.

If the Plain of Diarbekr is excepted, agriculture is limited to some tracts of moderate extent, to the numerous but narrow and short valleys, and a few plains and depressions which have a fruitful soil. The cereals which are grown are wheat, beans, barley, rice (in very few places), lentil, cicer arietinum, Lathyrus sativus, Secale cereale, Urtica, Holcus sordidus, and Medicago sativa. Other vegetables are several kinds of cucumbers, melons, solanum melongena, hibiscus esculentus, and pumpkins. The orchards and plantations of citrus fruits, citron, orange, and lemon, as well as the fourth species of figs, cherries, Armenian plums (prunus armeniaca), three other kinds of plums, apples, pears, quinces, cornelian cherries, almonds, walnuts, hazel-nuts, chestnuts, and cembra kernels (the latter species Carya cembra), castor-oil (ricinus communis), hemp, flax, safflower (carthamus tinctorius), cotton, and trigonum foenum-graecum, are also cultivated. Among the wild plants are capers (capparis spinosa), mustard (sinapis arvensis), liniacres (plenaria glabra), asparagus, and arum colocasia—the leaves of the last are used as paper.

Sheep, cattle, and goats constitute the wealth of the nomadic tribes, consisting of shepherds, nomads, nomadics (since a Khan), with the fat tail, which often weighs fifteen pounds, and the Arabian, whose tail is not much thicker than that of our sheep. Horses are numerous, but not so good as in the table-land of the Frat and Murad, or on the desert plains; asses are also kept in great numbers. It does not appear that camels are bred, but they are used on the caravan road.

The most common wild animals are wild boars, deer of two or three different kinds, wolves, foxes, fennel, jackals, bears, polecats, martens, marmots, hamsters (crictes vulgaris), squirrels, porcupines, and hares. There are several kinds of vaults, falcons, and owls; ravens, crows, jack-daws, thrushes, beccaz, and small birds, many of which also breed in both rivers, the Euphrates and the Tigris, and in several of their confluentes. There are also several kinds of turtles, snakes, and lizards.
Khorasan Toghi, is the town of Ilijch, which contains 1000 families, and where some cotton-stuffs are manufactured: in the neighbourhood maize is cultivated.

At the easter extremity of the Plain of Diaberk, within the Khorasan Toghi, in a very alpine country, runs a town called Biirk, on the sea-level, which contains 12,000 inhabitants, and carries on an active commerce with the adjacent countries and with Persia. It exports wool, tobacco, galingale, and gun-ungaeh, which are the produce of the country. From Persia it imports cotton for the manufactures of the town, which appear to be numerous; it has also several dyeing-houses and distilleries.

The southern termination of the Plain of Diaberk, not far from the base of the mountains of Kurdistan, 2750 feet above the sea-level. It contains about 5000 inhabitants, many of whom are engaged in dyeing red the cotton-stuffs of Bugs and Ilijch.

Along the caravan-road are the towns of Urfa or Orfa, Mardin, and Nishin. Urfa (Ora, the antient Edessa), the most western, is at the base of a hill, and is a well-built large place, which is frequently compared with Damascas. It is surrounded by high and strong walls, seven miles in circuit, and has between 40,000 and 50,000 inhabitants. It is not said that any branch of industry is carried on. The most remarkable part of the town is the grand mosque, which in its exterior and interior exhibits a considerable degree of magnificence. With this building are united several medresses, where a number of young men are instructed in the religion of Islam. Mardin, which is nearly at equal distance from Bir-eh-jik and Mosul, is built on the summit of a steep limestone hill, which may be considered as the termination of the Khasam Desert, and is about 2000 feet above the plain lying south of it. The population is differently stated between 10,000 and 15,000 individuals.

Nishin (the antient Nissia), farther east, had sunk down to the condition of a miserable village, but in modern times the Turks have begun to rebuild the town.

The town of Suverek or Severek lies on the direct road between Urfa and Diaberk, in a depression in the midst of the tableland. In its surrounding country it was raised to a considerable extent, and orchards are numerous. The place contains 2000 families.

The only place, except Diaberk, built on the banks of the Tigris which requires notice is Jezerib Ibn Omar (the Island of the son of Omar), which is built on an island in the river. It has long been the seat of a rebellious chief of the Kurds, and contains a population of about 1000. III. The third region, called the Desert of Mesopotamia, extends from the great caravan-road leading from Bir-eh-jik to Mosul to the Median Wall, or from 37° N. lat. to 33° 30' N. lat.; and as it forms the extreme of this vast plain, its northern extremity is nearly 300 miles wide; but the Euphrates and Tigris approach nearer to one another in their course to the south, the country grows narrower, and at its southern extremity it is barely 6 miles in breadth. It is about 500 miles north-west to south-east may be about 250 miles, and the average width about 150 miles. This gives an area of 37,500 square miles, or about 10,000 square miles more than Ireland.

This country has been called a desert, not on account of the sterility of the soil, but because till very recently we have been entirely unacquainted with its productive powers. That portion which has lately been seen by European travellers is far from being a desert, and has given rise to the opinion that in Mesopotamia there does not exist any tract of country of considerable extent which is covered with sand and utterlysterile, though a large portion of it is covered with horizontal layers of sandstone, which only during a small part of the year are clothed with grass and plants. But, on the other hand, there are some districts which exhibit a considerable degree of fertility.

The level of this region at its northern extremity and in the vicinity of Mardin, is between 1200 and 1400 feet above the sea, but it decreases as it approaches the river; Mosul on the table of its numerous mudhouses is the grand mosque, 650 feet above the sea-level. The course of the rivers and streams shows that it descends towards the south. At its southern extremity near the Median Wall it probably does not exceed 1000 feet above the sea.

The country is a plain, but there are a few isolated ridges of high hills, which however do not cover a great extent of country. The best known of these ridges are the Jebel Makhul on the banks of the Tigris, between 35° 30' and 35° N. lat.; the Sinjar Hills, south of Nishin, between 41° and 42° E. long., and of north of 36° N. lat., and the Abil-al-alz Hills, between 39° and 40° E. long., and near 30° 30' N. lat. The precise situation of the last-mentioned range has not been determined.

The most fertile portion of this region is in the north-western corner, between the Abil-al-alz Hills and the Pyramids of the Euphrates, which runs along about 100 miles, and falls into the Euphrates at Raqqa. This region comprehends the districts which are known by the names of Saruj and Harran. The fact of the fertility of this tract has only lately been brought to the knowledge of the Turks and Egyptians, when the army of the Turks drew provisions from this country. On this occasion Mr. Answorth was informed that in Saruj alone were more than forty large villages, inhabited by agriculturists, and that twenty of them cultivated rice. The country is considered as the granary of Syria, and no part of the last-mentioned province can vie with it in fertility and agricultural productions. Harran, which lies to the east of Saruj, is stated to contain a large portion of alluvial land, and to be equally fertile. The degree of fertility of the Abil-al-alz Hills is not known, nor their extent and direction.

We are totally unacquainted with the tract between these hills and the Sinjar Hills, except that nearly all the upper branches of the Khabur river rise in this tract, and this leads to the presumption that this tract is well watered, and that it contains a fair proportion of land fit for cultivation. It is also stated to be the case with the valley in which the Khabur river runs southward and south-westward until it reaches the Euphrates, near the castle of Rehabe, after a course of probably two hundred miles, about 100 miles in breadth.

The country between the caravan-road and the Sinjar Hills is nearly a level plain, which even at the end of the dry season is mostly covered with coarse grass and prickly plants. In some places there are tracts of marshy ground with long reeds, and interspersed with many large pools of sweet water; but at some places the soft soil is impregnated with salt. There are in this part considerable hills from 80 to 150 feet in height; they appear to be artificial. The portion of this tract which is under cultivation is small.

The Sinjar Hills run east and west with a slight inclination to the south. They extend in length about fifty miles, and in breadth from seven to nine miles. The highest part of the hills is near the eastern extremity, where they rise above 1500 feet above the plain. This is an agricultural district. Considerable quantities of wheat, barley, and bazaaria, in the lower and more level parts, and the sides of the hills are covered with plantations of fig-trees and vines, which yield articles of export. A portion of the hills is covered with oak trees, the acorns of which affords a staple article of food to the numerous wild boars which frequent the hills. The number of the inhabitants, who are Yezidis, is stated to exceed 6000.

The plain between the Sinjar Hills and the Tigris has an undulating surface, and is for the most part barren, and covered with coarse scanty grass and thorny shrubs; there are large tracts of barren marshy soil, strongly impregnated with saline matter. The most common vegetable production is an eat-grass, which at many places covers tracts of several miles in extent, to the exclusion of all other plants, except a few flowers. Cultivation is only carried on in some of the beds of temporary watercourses, and between some low ridges of rocks, where wheat and barley are cultivated. Some tracts are covered with wormwood. In the vicinity of the Tigris the cultivated tracts are more extensive, not on the higher grounds, which are covered with a black burnished fescue above the level of the river, but in the bottom of the Tigris. This river flows here in a valley from eight to ten miles wide; the projecting headlands of the higher country form large embayments called hesas, which have a fertile alluvial soil, overgrown in their natural state with grass and small tamarisks, but where cultivated giving abundant crops of grain or rice.

In proceeding from Mosul southward the cultivated tracts decrease in number, as the agricultural inhabitants are too much subject to the predatious incursions of the Shummar Arab who are in possession of the uncultivated interior of this part of Mesopotamia.

The Jebel Makhul extends about forty miles along the banks of the Tigris, and at a very short distance from 35° 30' close up to Vol. II. — 2 P
the banks of the Tigris from the south-east. The Jebel Makhul may rise about 600 feet above the level of the river: it consists mostly of tuffs, and is composed of one mass of tuff in the present compass. In its present state it is a waste plain, but its western base is a large tract of country with a sandy soil, which contains a great number of bitter wells that are frequently visited by the nomadic tribes of the Arabs. The banks of the Tigris are much higher than the plain of Tefrit, and the town of Tefrit is uninhabited on account of the neighbourhood of these tribes. Between Tefrit and the Median Wall the alluvial tract on the banks of the Tigris grows much wider, and appears to have been of late years an extensive tract of swamp land, which was irrigated from a large canal which still exists under the name of Ishaki, and extends from the town of Tefrit to Bagdad; a great number of smaller canals of irrigation are connected with it. But the present course of the river, which maintains its course, as the whole work has gone to decay from want of attention; and this tract, which has an exceedingly fertile soil, is without inhabitants, and almost without cultivation, except a few isolated spots.

The higher ground west of this alluvial tract, as far as the river Tharthar, has an undulating surface, consisting mostly of long ridges, and depressions between them, not unlike the waves of the sea. In the valleys between the higher grounds the soil is moist even at the end of the dry season, so as to afford pasture-ground nearly the whole year round. But the best pasture is in the valley of the river Tharthar, which flows into the Tigris. This river is said to rise at the base of the Singir Hills. It runs parallel to the Tigris and about twenty miles from its banks. In May it was found to be between fifteen and twenty feet deep to seven feet deep. Its course may perhaps amount to one hundred and fifty miles. The water is brackish in summer, but not unpleasant to drink. The bottom in which this river runs is sometimes a mile wide, but in other places narrowed by the projecting headlands of the higher grounds to two or three hundred yards. It does not appear to be cultivated, but on the western bank are extensive ruins of Al Hadr (the ancient Hatra), which must have been erected in a country which was well cultivated. The Tharthar falls into a salt lake, somewhat north of 34° N. lat.; this lake is called El Mill, or the Lake of Ashikil; its extent is not known. The country west of the Tharthar river, as far as the banks of the Euphrates, is entirely unknown. It is said that at some places rock-salt is found in this desert.

The country contiguous to the banks of the Euphrates is much better cultivated than that which skirts the Tigris. Between Bir-chilik and Balis the Euphrates runs in a narrow bed between very high rocks; there is no bottom on the banks of the river, and the adjacent country is sterile and uncultivated. But between Balis and Racca the high grounds present a low and rounded character, and the river rises from one mile to six miles distant from the banks of the river. The bottom in these parts is an alluvium. On the banks of the river are tamarisk-bushes. A great part of the low land is overflowed, and the more extensive tracts between the swamps are either overgrown with tamarisk-bushes or used as pasture-ground. There is hardly any cultivation. In these parts the bed of the river is wider, and there are several islands of date-trees.

At the mouth of the Khabar river are some extensive woods, composed of high trees, especially tamarisks and poplars. Lower down the low and level flats increase in extent, and here also cultivation is much more attended to, but still by far the greater part of the bottom is swampy, or only partially cultivated as pasture. The number of islands increases as we proceed farther south; they are partly bare and partly well wooded with tamarisks. Before reaching Annah cultivation begins again to be more general. Round this place a large tract is well cultivated; corn, cotton, French beans, and sesame are raised to a great extent; the plantations of dates are extensive, and the numerous orchards yield oranges, lemons, pomegranates, figs, and olives. The olive-tree is not met with farther south; but the other trees and branches of agriculture are greatly attended to, in the bottom of the Euphrates as far down as Hitt.

The banks of the river present a continual plantation of date-trees; and between them and the low, rounded, gently sloping hills at the back, the bottom is, with the exception of some swampy ground, a high state of cultivation, and full of villages. A great part has been devoted to the irrigation of this part of the valley, which has been sowed to the system of irrigation which has been introduced. A great number of canals traverse the river bottom in different directions, extending from 200 to 3000 yards from the banks, and their water, raised by machinery, is distributed over the adjacent lands. The numerous islands which occur in this part of the course of the Euphrates are mostly cultivated, and on some of them towns are built.

Opposite to Annah, the bottom is only a mile wide, and nearly without vegetation, as the surface is mostly composed of gravel, intermixed with flint and pieces of chalk. There are only a few date-trees, poplar, and tamarisks; and the land is mostly a continuation of the plain of Tefrit and the bottom of the river. Below this place the high grounds disappear entirely, and the whole country is very little elevated above the level of the river. The soil of this tract is extremely soft, and as the banks are close to the river, which was irrigated from a large canal, the water of which is greater than 100 feet high. There are no longer any canals, nor any cultivation. The whole tract is in possession of nomadic tribes, who find here during the dry season abundant pasture for their buffaloes and horses. The number of islands in the river decreases, and they are not longer cultivable; their soft soil consists of sand and mud. Such is the country between Hitt and the Median Wall.

The Median Wall runs from the banks of the Euphrates to those of the Tigris. Its southern extremity is said to be on the Euphrates, a little above Shab; but at this point it has not yet been recognised by European travellers. Its northern extremity is found somewhat north of 34° N. lat.; so that it runs in a straight line from N.N.E.E. to S.S.W. for 130 miles, being on an average 25 long paces thick, with towers or buttresses on its western face every 25 paces; and on the same side it has a deep ditch, 27 paces broad. Near the Tigris it is built of the small pebbles of the country. It is from 8 to 12 feet in height. The natives say that in places far inland it is built of bricks, and in some parts worn down with the desert. According to their tradition it was built by Nimrod (Nimrod) to keep off the people of Niniveh (Nimrûd), with whom he had an implacable feud; and they call it Shad Nimrûd, or Chalû (embankment). We know nothing of the antiquity of this wall, except that it is mentioned in existing n. c. 401, when Shalmaneser and Greeks were commencing their retreat from the field of Cunaxa. Xenophon (Anab. ii. 4) describes it as built of baked bricks lying in asphalt, as 20 feet wide and 100 feet high; the length was said to be 20 parasangs (600 Greek stades); and it is not far distant from Babylon.

Our knowledge of the climate of this region is limited to a few general notices. The heat in summer is very great, and no rain falls up to the middle of November. During November and December the rain falls in frequent and heavy showers, but is not continual. In January and February there is a good deal of frost, and after the spring has commenced in March and April, the earth is searched there as elsewhere. The heaviest rains fall in the month of May, when the heat becomes so much less as to dry up the pasture of the swamped parts, and compel the nomadic tribes to seek shelter in the higher and drier parts of the country, and return to the Euphrates, and to the valleys of the Tharthar and Khabar.

This region is divided by the pashalis of Mosul and Bagdad. No remarkable places are found, except the towns built on each side of the two rivers which enclose the region. On those of the Tigris are Mosul [C. P. C., vol. v., p. 447] and Tekrit, which is built on a cliff, and occupies the eastern part of the site of an ancient town, the ruins of which are very extensive.

The largest towns on the Euphrates are in the fertile tract which extends from Annah to Hitt. Annah (the ancient Anatho), which is partly built on the western bank, and partly on an island of the Euphrates, contains 1800 houses, and is considered the capital of the Arab tribes inhabiting the west of the river. Farther down lies Hedinah, on an island in the river, in the midst of date plantations, and contains more than 400 houses.

El Us is a considerable place, and like Annah partly built on an island. Jibbab, another town built on an island, contains 500 houses, and is a thriving place. Hitt (theSite of the old city of Resafa, i. 179) contains 2000 houses, which are mentioned by Herodotus. It is built round a hill, and has good houses of stone. In the vicinity there is very little cultivation, and the inhabitants derive their subsistence from making salt, preparing goat's hair, and manufacturing little earthquakes.

The number of bitumen springs in the neighbourhood of this place is very great, and the produce of a single spring is sufficient to meet the demand, though it is used in these parts as an article of food. A great number of rivers, and forms are made here. They consist of wicker-work,
made of branches from one and a half to two inches in thickness. The interstices are filled up with bark or straw, and then the whole is caulked with bitumen. In such boats the bitumen, salt, and prepared lime are taken to Hilma, Basoom, and other places by which numerous small vessels pass through the channels which lead from the main river to the coast. These small vessels are the black tents of the nomadic Arabs. By this canal the wicker-boats of Hilt bring the produce of the country contiguous to that place to Bagdad, and it has twice been navigated by steamers. Before the Tigris it falls into a large lake called the Hor, which lies west of the town of Bagdad; a canal about five miles long called Mosaic, carries the waters of the Hor into the Tigris. It is also navigable for steamers.

The Samawiyah is considered to be the Is canal of Albufla, who mentions three other canals farther south, which cross the whole width of Babylonia, and these canals still exist. They are called, from north to south, the Nah Abu Gharib, the Nah Melik, and Nah Dhiyah. We have no particular account of these canals. These four canals leave the Euphrates between 35° 30' and 39° 30' N. lat. The mouths of some other canals are seen farther south, as far as the ruins of Babylon, but it is not known how far they extend inland.

The principal canal in the southern districts of the plain of Babylonia is the Shat el Hiyek, which carries the water of the Tigris to the Euphrates. It leaves the Tigris opposite Kut el Amarn, a miserable village on the eastern bank of the river, near a hundred miles below Bagdad in a straight line, and in a time of flood runs 178 miles in its bed, and is called the Shat el Hiyek. It runs more than a hundred miles southward, and enters the Euphrates nearly opposite Arge or Abbe, about fifty miles above the confluence of the two great rivers, on the banks of which the Turks built the Bost Jeirnit and the eastern Sayid Nawain; their mouths are about five miles apart. The tide ascends the Euphrates as far as Arge. This canal is dry in summer, but during eight months it is navigable, and in winter it is 150 feet wide and rather more than two fathoms deep. In this period of the year it was navigated by a steam-boat during the late Euphrates expedition; but only the western branch is navigable, the course of which is confined to the channel of the settlements, and a considerable traffic is carried on by it. At no great distance north of the western mouth of the Shat el Hiyek is that of another large canal called the Shat el Kar. It runs also from north to south, but it is not known where it originates, and whether its northern extremity is connected with the Nah Dhiyah. It was crossed by Fraser at a considerable distance above its mouth, where it was from 30 to 40 feet wide, and knee-deep in summer, but in winter it is fordable only in a few places. Like the Shat el Hiyek, it is navigated by the river boats, which are made at Hilt.

The banks of the Euphrates, from the place where the Sablawiyah canal meets, to a certain point, that runs about 20° to the east of the Sablawiyah, are of moderate height. The country adjacent to them is of indifferent fertility, and is mostly overgrown with grass, which is sometimes deep enough to float a boat. The few spots on the banks, and the pastures-grouds near them, are also indifferent, the number of cattle, sheep, and goats is not great. It appears to be but little inhabited, and only from time to time a grove of date-trees is seen.

The country near the sea, on the coast of Persia, is large portion of it is under cultivation, and the plantations of dates are more numerous. It is a populous country: between Hilla and Dhiwanyeh a number of large villages are observed, the population of which was estimated by a traveller at 10,000 individuals.

A short distance south of Dhiwanyeh begin the marshes of the Euphrates, which, lower down, are called the marshes of Lembayun, or Graham Inlet. About 30 miles north of the Castle of Fuljiah, and not far south of the place where, according to the accounts of the native, the Median Wall terminates on the banks of the river, and reaches the Tigris below Bajilid. Though the direct distance between the two terminations of the canal is not more than 45 miles, its length is 70 miles, because for two-thirds of its course near the Euphrates they are many benda; the last third runs nearly in a straight line, and is frequently fifty yards wide. But where its course is not direct the canal is very narrow, so that the steam-boat navigated it with difficulty. This river, however, is the Black or Gharat, which runs four miles an hour, and the lowness of the banks, which never rise above the level of the adjacent country, and are frequently lower, appear to prove that this part of the Sablawiyah is a portion of a running stream not a canal. Near the Euphrates the banks are thickly dotted with bushes of liquorice, which grow to the height of ten feet, and have roots of considerable thickness; these roots give consistence to the soft soil of which the banks are composed. Further on the country adjacent to the canal presents a boundless prairie, over which nothing of cultivation can be raised. In the rear, however, are the black tents of the nomadic Arabs. By this canal the wicker-boats of Hilt bring the produce of the country contiguous to that place to Bagdad, and it has twice been navigated by steamers. Before the Tigris it falls into a large lake called the Hor, which lies west of the town of Bagdad; a canal about five miles long called Mosaic, carries the waters of the Hor into the Tigris. It is also navigable for steamers.
Mesopotamia is also called the canal of Yusuf (Joseph). It begins about half an hour above Diwaniyeh and terminates at Gharah. The supply of water extends for seventy places wide, and its course lies nearly parallel to the Euphrates, at a distance of about 2 or 3 miles from its northern branch. The canal of the Arabian side is called the canal of Old Lamlun. It begins at the town of Alash, 72 miles beyond Diwaniyeh, and rejoins it a short distance above the mouth of the Yusuf canal. The two canals are connected with the Euphrates by numerous other canals of smaller dimensions, and others by a number of irrigation canals from the parts of the marshes which are more distant from the river. The numerous population derive their subsistence from their fields of rice, which extend over all the higher grounds, which are dry in summer, from their herds of buffaloes, and from the abundant pasture in the marshy tracts, and from their plantations of dates, which cover the banks of the numerous canals. They also have a few plantations of fig-trees. During the inundations the whole surface of these marshes is under water, with the exception of those places which are enclosed by embankments, and some more elevated tracts on which the villages are built. The villages also are frequently inundated, and when this happens, the inhabitants convert the roofs of their reed-built huts into boats, or place their families on buffaloes, and in this way reach a more elevated spot. It is very difficult to enter their country with any force, they are never ravaged by the paya or squirel of the region, the Fasha of Bagdad. The Euphrates in their country contracts very much in width, so as to be at some places not 200 feet across, and the Kasheel Araby levies a very arbitrary toll on vessels which navigate between the lower and middle course of the river.

The marshy tracts terminate at Grahim Inlet, and with them the large canals for irrigation: farther downward only small narrow cuts are met with, which serve to irrigate the tracts adjacent to the banks of the river, and do not advance far inland. The banks are more elevated, though not high, and in most places overgrown with bushes. This country is inhabited by the Montal Arabis, who form a mixed race of cultivation and pastoral occupation: the inhabitants have begun to cultivate the ground, but they have not quite got rid of the habits of a nomadic life. The country is covered with villages and tents mixed together. As the country is rather fertile, it is well inhabited, but not so populous as the marshes of Lamlun. The date plantations are as numerous and extensive as at any place higher up the river, but less care is bestowed upon them and on the cultivation of rice and wheat.

Those inhabitants who still adhere to a nomadic life have large herds and flocks of horses, camels, buffaloes, sheep, and goats. The tract of ground between the mouth of the two canals Shah of Kar and Shah of Elhy is swampy and half wooded, but little inhabited. But below the last-mentioned watercourse the country rather improves; the banks of the river present almost a continuous forest of date-trees, between which are found small lakes that are connected almost one another: on approaching the place where the two rivers unite, the banks of the rivers sink lower, and large tracts are seen, which in many extensive fields still occur, on which wheat, rice, and barley are grown. The uncultivated fields are used as pastures for the numerous herds of buffaloes. From ten to twelve miles from the confluence of the rivers, the waters of the Tigris are so abundant that the country is converted into a swamp, which during part of the year is covered with water many feet deep, and in the dry season it is cut up by numerous watercourses. This district is nearly uninhabited.

The Euphrates fertilizes the long country which extends on both its banks below the town of Diwaniyeh, as the Nile does the Delta of Egypt, but in a different way. The healthy climate, the richness of the soil, and the heat of which is similar to that of Egypt, as much as to the fertility of Egypt as the moisture with which its soil is saturated during the inundations. The fertilizing power of this sediment is ascribed by Ruppe to the hot sand blown from the deserts of the region, especially from the mountains of Abyssinia in a volcanic region of great extent. The Euphrates does not pass through such a region, and the detritus which it brings down is formed by the abrasion of the bed of the river and by the action of the weather on the clay. This soil is not fertile itself, but becomes so when irrigated. This advantage is partly obtained by the inundations, and partly by machines of different descriptions, or by hand, when necessary. The area, extending from the first of November to the end of the year. It then begins to rise slowly, and continues to rise to the middle of January. This rise is probably contributed to the great quantity of rain which falls in the second, third, and fourth months from 15 to 18 feet. Were this great volume of water permitted to rush down on the low country, it would entirely submerge it, and convert it into an immense swamp. To prevent this great volume of water from overflowing the country, and from Rioting the inhabitants, and from injuring the crops and fields, the regulating is done with a great deal of care. The farmers usually order the first collection of waters to be a little sunken, so as to receive the movement of the Euphrates, and to prevent any great accumulation or overflow. The reeds and rushes which are found on the banks of the river, and which are used for building purposes, are of great service in this respect, and are not allowed to be beaten down. The quantity of water is regulated so as to fill the channels of the smaller canals, which are used for irrigation, and to prevent any great accumulation of water. It is regulated also by means of the dikes which are usually constructed by the farmers, and which are called by the name of Shat El-Esha. These dikes are usually constructed of reeds and rushes, and are usually ordered to be about 15 feet high, and 15 feet wide. They are usually constructed at the time of the first collection of water, and are usually ordered to be kept in good order, that the water may pass through them without obstruction.
Mesopotamia is inhabited by nations of different origin. Owing to its position between two table-lands inhabited by nomadic nations it has been frequently beset by its neighbours, and it appears that they have expelled the original population, for the greater part of the country is inhabited by people whose ancestors have settled there within the period of recorded history. Those nations who claim to be aboriginal are the Armenians and the Yezidis. The Armenians are dispersed over the table-land of the Frat and Murad, and the HilIy Region of Mesopotamia. The first-named region is part of the Frat and the second of the Murad. It appears that until lately these three nations were almost equal in numbers in that country, but since the last war between the Turks and Russians many Armenians have left their country and gone to settle in Georgia. In the HilIy Region of Mesopotamia the number of Armenians is small in comparison with the Turks and Kurds. They are an industrious people, who occupy themselves with agriculture, the mechanical arts, and especially with commerce, by means of which they acquire wealth, and get into favour with the ruling nation, the Turks. They are Christians of the Greek Church.

The Yezidis are a small nation, who exclusively inhabit the Sinjar hills, and also isolated tracts in the eastern districts of the hilIy region of Mesopotamia and in Kurdistan. Though they are said to be descendants of the ancient inhabitants of Moawiyah, the destroyer of the race of Ali, they are evidently different from the other nations of the country. They are of a muddling size, and have a clear complexion, with regular features and dark eyes and hair. They are keen, active, muscular, and well proportioned. The hair is long wound and the beard and whiskers kept close shorn, but they are prohibited from cutting or dressing the mustachios. Their religion is a strange mixture of the practices of the Arabs and the Magi. They celebrate the festival of Madru under the name of the Yezidis in the sun as symbolic of Jesus Christ. They have no fixed place for prayer or worship, but occasionally visit the Christian churches and monasteries, and present offerings there on recovery from sickness or escape from danger. They are brave, hospitable, and sober, faithful to their promise, and much attached to their native soil, but cruel and vindictive: they consider their proper means of support to be robbery and theft, and they treat with great barbarity any unfortunate Mohammedans who fall into their power, especially Persians. They are industrious in cultivating the soil and managing their orchards and plantations.

The Kurds are a people who are partly considered as an original people. It is probable that when the Armenians generally adopted agriculture, those parts of their country which are unfit for cultivation, owing to the rigour of the climate, remained or became uncultivated. The possession of these tracts spread over these mountains from their own country. Where such tracts unfit for cultivation are extensive, the Kurds have adhered to their nomadic life, and are almost independent of the ruling nation. Where however agricultural and pastoral tracts of country are intermixed, they have partly acquired the habits of cultivators of the ground, but they still maintain an inclination to a roving life and to predatory excursions. They take great care of their cattle and sheep.

The inhabitants of Turkish origin are numerous in the table-land of the Frat and Murad, and in the HilIy Region of Mesopotamia, but they are thinly settled in the two southern regions. They doubtless settled in these countries at the different periods when Mesopotamia was conquered by the nations who inhabit the table-land of Iran, where the original inhabitants had been driven to the north. In Mesopotamia they are agriculturists, and carry on different trades in towns and villages. It does not appear that any of the Turkish tribes in Mesopotamia still adhere to a nomadic life, as is the case in carrying on trade. The Ottomans are only soldiers or employed by government as civil officers.

As northern Mesopotamia has derived a considerable part of its present population from the table-land of Iran, the southern regions, with the exception of a comparatively small portion, are occupied by tribes which have descended from the table-land of Nejd in Arabia; and this immigration, as it

Bedouin of Baghdad, which is not supplied with provisions from the lands in its vicinity, but from that part of Kurdistan which lies farther north. Baghdad is indeed surrounded with extensive gardens and some fields, but they extend only a few miles from the walls, and are surrounded by a uncultivated district. North of the town the plain is traversed by the great canal called the Ishabi, which extends from the neighbourhood of Tekrit to the Sakifawiya canal, but is without water. There are also many other canals of smaller dimensions in the same valley. The Shat El Arab probably contains a very small quantity of water all the year round, and in its vicinity are a few large villages, surrounded by orchards and plantations. The remainder of this tract is pasture-ground for the herd of the shepherds. North of Baghdad there is still less cultivation. The country is quite flat, and in most parts a grassy prairie, well watered; in others, covered with extensive swamps. A few small cultivated spots appear at great intervals. Herds of buffaloes however, and the black tents of the nomadic Arabians, are common. There are hardly two or three villages which have a permanent population. As we approach the confluence of the Tigris and Euphrates, nothing is seen but stagnant water, swamps, and morasses, in which single families have settled, who live on the milk of their buffaloes and the little rice that they can obtain.

The interior of the Plain of Babylonia is very imperfectly known. It appears to be considerably elevated above the tract adjacent to the rivers. The northern part, or that which lies between the Euphrates and the Shat El Arab, is a low undulating surface. The soil is composed of sand and pebbles, and in most parts overgrown with coarse grass, mimosa, and thistles. The water is generally brackish. Between the low sandy table-land and the higher parts there is an expanse of flat land, where the water is more abundant, which appears to be covered with a considerable space. In many parts efflorescences of nitrates and other salts occur, which in some places form nearly a white crust on the ground. On the banks of some of these efflorescences, and sometimes in the middle of the flat land, are a number of springs, which appear to cover a considerable tract. They form such masses that in the level country they are frequently taken for natural hills, until a closer examination shows that they contain a number of pieces of earth, stones, and bricks, like those found in the ruins of Baghdad itself. In some of these fragments of columns have been found.

With respect to the climate of this region the reader is referred to Baghdad [P. C., vol. iii., p. 272], the remarks in which article may in some measure be applied to the whole region. Its productions areenumerated in the Pashalik of Baghdad [P. C., vol. iii., p. 296]. Besides the town of Baghdad, a few places occur on the banks of the Euphrates which require notice. Hillah is a fortified place with about 25,000 inhabitants, Arabs, Persians, Turks, Jews, Armenians, and Indians, in the midst of a number of villages, and is also filled with mosques, It carries on a considerable commerce with all the towns on the Euphrates, mostly in river-barges of 50 to 80 tons. The imports consist especially of rice, dates, fish, oil, coffee, continuation of a number of pieces of earth, stones, and bricks, like those found in the ruins of Baghdad itself. In some of these fragments of columns have been found. Hillah is a fortified place with about 25,000 inhabitants, Arabs, Persians, Turks, Jews, Armenians, and Indians, in the midst of a number of villages, and is also filled with mosques, It carries on a considerable commerce with all the towns on the Euphrates, mostly in river-barges of 50 to 80 tons. The imports consist especially of rice, dates, fish, oil, coffee, continuar
would appear, is from time to time renewed. Many of these Arab tribes have changed their mode of life, which appears away to have been the case when the migrating tribes were not powerful enough to occupy large tracts of pastoral ground, and they directed their efforts for cultivated lands where they settled and became cultivators. There is a consider­able number of small Arabic tribes in the desert plains of Mesopotamia, and they always cultivate only a small tract of ground. The more powerful tribes took possession of extensive regions, and even where the country was fit for cultivation, they converted it into pasture-grounds for their horses, camels, and sheep. Some of them have preserved their nomadic habits to the present time; they are especially the case with the powerful tribe of the Shammar, which is in possession of the countries adjacent to the Tigris river from Mosul to Bagdad and nearly of the whole of the Great Desert. It is only in the vicinity of the Euphrates that a portion of an equally powerful tribe, the Aneizah, is found, but the principal seat of the last-named tribe is in the desert which extends from the Euphrates to Damascus. The cultivable tracts of the desert are in possession of some smaller Arab tribes, who are tributary to the Shammar. Other Arab tribes have been compelled by the physical nature of the country occupied by them to change their mode of life. This is most conspicuously the case with the Bedouin of Kasandal, which inhabits the marshes of Lamian. This region does not afford pasture for camels, horses, or sheep; it is, however, fit for buffaloes, for the cul­tivation of rice, and plantations of date-trees. The inhabitants of this district have been compelled to adopt the habits of the occupiers of swamps, but they have preserved their activity and their spirit of independence. The numerous tribe of the Moutefik occupies the long banks of the Tigris the whole compass of it, and the Kerna in the Barbourah, a tract which extends from the marshes of Lamian to the confluence of the two rivers. At the back of the marshes some smaller tribes are settled. That portion of the tribe of Moutefik which has settled on the Tigris has almost entirely on the produce of their herds of buffaloes, cultivating occasion­ally a small spot of rice-ground. On the Euphrates the habits of the Moutefik are much more agricultural: the date-plant­ations are their chief business, and constitute their principal wealth, but their richer classes have not yet entirely got rid of their nomadic inclinations, as they still prefer to pass their time with their herds of horses and sheep in the interior of the country, whilst the poorer portion of them cultivate their rice-fields and manage the date-plantations. Travellers however observe that both the fields and plantations do not exhibit that careful cul­tivation which is observed in other parts of Asia where the habits of the people are entirely agricultural.

It would be an almost endless task to enumerate all the political changes to which Mesopotamia has been subject since being was named in history as the birth-place of Abraham. There is much space in the course of the globe there have been so frequent and so great. From the sway of the kings of Babylonia Mesopotamia passed successively to that of the Assyrians and Medians, and then it was subdued by the command of Cyaxares, and from this time there were two powers in the country, the Greeks and the Persians. After the battle of Issus it fell into the power of the Macedonians, and after the death of Alexander his generals Antigonus and Seleucus successively possessed of it. Seleucus founded the kingdom of Syria, of which Mesopotamia formed a portion, until the countries belonging to the Persian kingdom were divided between the Romans and Parthians. During many centuries Mesopotamia was the theatre of the wars in which these two nations contented for superiority until the Parthians were supplanted by the Persian dynasty of the Sassanids, when Mesopotamia was dismembered between them and the Greek em­pire of Antioch. But at last the Persians appeared, and their caliphate established the seat of the wide-spreading empire in Mesopotamia. Since the destruction of the king­dom of Babylonia, the country had not enjoyed so much pros­perity as under the Persians; but after the Medes and prcises had lost their power, Mesopotamia fell into the hands of the Turkish princes, the Sejukas and Atebeaks. About the beginning of the twelfth century a portion of it was conquered by the Crusaders, but the power of this country did not keep them, and the country had been laid waste by the continual wars of the Mo­hammedan princes, it was invaded by the Mongols, who however soon left it, and then Mesopotamia again returned to its original condition, but after the Crusaders had left the country, the Musulmen renewed their conquests over this part of Asia. Their progress was for a time interrupted by the famous Timur, but after his death the Osmanias again

acquired the ascendancy, and subdued the whole of Mesopo­tamia to their dominion in the beginning of the sixteenth century. Since that time no political change of importance has taken place.

MESPLUS, a genus of plants belonging to the natural order Rosaceae, and to the sub-order Pomeae. [Pom­me, P. C. S.] It has the eulyx 5-cleft, the segments foliaceous, the petals nearly circular, the pome 6-celled, the styles 3-6, the fruits 2-5 glabrous; the pome turbinate, open, 5-celled; the endocarp bony. The species are trees, natives of Europe, and in a wild state are furnished with spines, which all disappear on cultivation. The flowers are large, nearly sessile, and white.

M. Germanica, the common Medlar, has lanceolate undivided leaves, downy beneath, and solitary flowers. This plant is a native of Europe and Siberia. It is found in Great Britain in hedges and thickets in Surrey, Sussex, and Cheshire. It is cultivated on account of its fruit, which is eaten in a state of decay. Its taste and flavour are peculiar, and greatly esteemed by some persons. De Candolle describes three wild varieties of this species of medlar. The following are the garden or cultivated varieties:—

1. Blake's large medlar.
2. The Cornish, a large Dutch, broad-leaved Dutch, or large German medlar. It bears the largest fruit of any of the cultivated medlars.
3. Stoneless or French medlar, has small oblate fruit, not much esteemed. It is the result of a very remarkable variety.
4. Notting-ham, common, small-fruited, or narrow-leaved Dutch medlar. It has an oblate middle-sized fruit, and is the best of all the medlars.

M. smithii, Smith's Medlar, has obtuse elliptic serrated leaves, pubescent on the nerves beneath, the flowers usually solitary. The native country of this plant is unknown, but it seems to have the characters of a true species. It has white flowers, which are one-half smaller than those of the common medlar. The stipules of the sterile branches are large and foliaceous.

The similar may be propagated by grafts or by layers, or by grafting upon seedling stocks of their own species or any kind of Pomacea. Forsyth remarks that the kinds of Mesplius do better by grafting on their own stocks. The soil best adapted to the plant is nearly sandy, and neither moist nor dry, but not on a moist bottom. It may be grown either as a standard or an espalier. The general horticultural treatment should be similar to that of the apple-tree. For a description of the pomaceous genera of Rosaceae, see POME­me, P. C. S.

(Don, Gardener's Dictionary; Babington, Manual of Brit­ish Botany; London, Arboratum et Fructicetum Brit.)

MESSENGERS AT ARMS are the officers who exe­cute the writs issuing from the supreme courts in Scotland. The duty of executing the king's writs and injunctions ap­
ears to have rested with the Lyon King at arms, aided by
the heralds or other assistants. To this day the Court of
the Lord Lyon has authority in the admission of messengers at
arms, in the impugnation of their conduct, and in their dis-
mission for the proper and legal performance of his official duties.
Messengers require to perform their functions with great pre-
cision, as they are not only amenable to questions regarding the
laws of arms, but to the law of arms as well. For the legal accuracy of
which the title to landed property may
afterwards depend.
METAMORPHOSIS, VEGETABLE. [VEGETABLES, METEOROLOGY, C. S.]
METEOROLOGY. [ELECTRICITY, ATMOSPHERIC, P. C. S.]
METOPTA, a genus of fossils (allied to Patella?), proposed by Professor Plutarch. From the mountain limestone
of the north of England.
METRORUS, a distinguished antient painter and
philosopher of Athens, born about two centuries before the
Christian era. After the defeat of Perseus by Paulus
Emilius, in Greece, n. 618. The Roman general ordered the
Athenians to send him their most able painter to per-
testate his triumph, and his most distinguished philosophers
to educate his sons. The Athenians said Metrorus the extra-
ordinary honour of declaring to Paulus Emilius that he was
both their greatest painter and their most distinguished phi-
losopher ; and the Roman general is said to have been per-
fected before the day appointed.
As Metrorus was chosen to paint the triumph of Paulus
Emilius, and to educate his sons, and gave him satisfaction in
both respects, we must infer there is a certain amount of
talent contained in the picture. It must have been
an undertaking of great magnitude, and indeed, if ade-
quately represented, a very extraordinary performance, for in
the procession of this triumph, which is partly described by
Plutarch, there were two hundred and fifty wagons con-
taining Greek works of art: the spectacle lasted the entire
day.
(Pliny, Hist. Nat. xxxiv, 40; Plutarch, Paulus Emilius,
32.)
METROPOLIS. [Colony, P. C., p. 366.]
METROPOLITAN. [ARCHBISHOP, P. C.]
METROPOLITAN STAGE-CARRIAGE. Before pro-
ceeding to give a brief notice of the law relating to hackney
and stage carriages in London, we may quote, from two inter-
esting papers on the 'Vehicular Statistics of London,' in
'Chambers's Edinburgh Journal' for 1845 (Nos. 76 and 78,
New Series), some statements relative to such of the public
vehicles of the metropolis as are not embrace in the article
HACKNEY-COACH, P. C. S. These papers, we may observe,
are the more reliable, because they have
The distinction between hackney and stage carriages is
pointed out under HACKNEY-COACH; and the origin of
that class of stage-carriges, which has almost entirely superseded the
chaise landau, is in the London, not in the
omnibus, P. C., p. 437. 'Fifteen years ago,' observes
the writer of the papers above referred to, writing in 1845,
'a few very slow and uncapital stages were the only means
of transit provided for the citizens to convey them to their
suburban residences.' 'A little earlier,' he adds, 'only one
stage plied from Paddington to the Bank, along a road which
an omnibus now passes every three minutes in the day;
and this single vehicle, going in the morning and returning at
night, was not always full. Its fares were two shillings in-
side, and eighteen-pence outside.' The old stage-coaches
could only carry four, or at most six, inside passengers; and when the number of passengers about the year 1800, to introduce
a more commodious kind of vehicle, resembling an omnibus,
the project failed, in consequence of a general prejudice against the horse-like appearance of the carriage. The long-
ness of the carriage was the chief object of dissatisfaction,
and six wheels (Knight's 'London,' vol. i. p. 32.) When re-
introduced from Paris, the omnibus had four wheels, but was
much longer and heavier than at present, and was drawn by
horses harnessed abreast. About the year 1830, to introduce
omnibus as being the best mode of applying the power of the
horses in drawing, was soon abandoned, it being found that
the middle horse was distressed and injured in a carriage
on each side. The first successful omnibus in London was started by a coach-builder named
Shillibeer, in July, 1839, to run between Greenwich
and Charing-Cross, at fares considerably less than those of the
old short stages; in addition to which advantage, the greater part of the passengers were sheltered from the weather.
By the judicious arrangement of making the same charge for
inside and outside places, Shillibeer soon obtained extensive
patronage, and by the development of the omnibus system, the
clausiveness which formerly distinguished inside from outside
passengers. Success in the first experiment led Shillibeer
to establish omnibuses between Paddington and the Bank.
In the omnibus, not vice versa, as it was so much regretted that the person to whose enterprise London is indebted for
so great a boon, though thus prevented from reaping
his reward, should never, so far as the writer is aware, have received a testimonial for his important services.
In the course of the contest between Shillibeer and the
old proprietors, and of the subsequent quarrels and rivalries
among themselves, the omnibus system fell into disgrace in
consequence of the furious driving, want of punctuality,
and general ruffiandy conduct of the men employed as drivers and
conductors, or, as they were popularly called, 'cads.' These
evil led to the establishment, in 1836, of a joint-stock associa-
tion called the London Omnibus Company, which
posed to establish omnibuses along the principal lines of
traffic, starting at short and regular intervals, and conducted by men of sober and respectable character, who were strictly
forbidden to ride faster than a walking pace. The result
of this experiment was so successful, that on the lines
which yet remained in private hands the proprietors found it to be
necessary to follow their competitor, and the whole system
itself into associations of similar character. In the course of
a few years the association system was almost universally adopted,
and now, while on many lines of road the omnibuses belong
to several different individuals, there is hardly an instance
in which these individuals are not united in some compact which
prevents competition, and secures community of interest
among all the carriages running the same road, or rather among all running to and from the same termini. On the
Paddington road, after a competition for some time between
the London Conveyance Company and the association formed
by the old proprietors, the two bodies united to 'work the
roads' for their mutual advantage. Paddington is the sub-
urban terminus of two very important lines of road, each of
which has also a common City terminus at the Bank of
England. One of these lines follows the course of the City
Road and New Road, by Islington, Hoxton, and the
northern suburbs of London; while the other takes a more
direct course through the heart of the metropolis, by Holborn
and Oxford Street. For working the last-mentioned line the
London Conveyance Company have, some years ago, referred to at the commencement of this article, eighty-two omnibuses,
and not less than a thousand horses Each of the
omnibuses performs, upon an average, six journeys (that is,
from morning to night, and, therefore, eight,) by two or
three horses to work it, independent of casualties. These
horses are selected for strength and activity, and an experienced veterinary surgeon, with a staff of assistants and farriers,
besides upwards of eighty horse-keepers or grooms, are em-
ploved to attend to them. These are independent of eighty-
two drivers, and as many conductors, so that nearly three
hundred persons are employed by the Company, for the service
of this one line of road. The journeys are performed at in-
tervals of from one and a half to three minutes, according to
the time of day; and as each omnibus makes six double jour-
nies, of about nine miles each, the total number of journeys
run daily is 492. At the number of miles driven is about
4428. 'Supposing,' observes our authority, 'we take as an
average ten passengers for each trip, the gross receipts of
the London Conveyance Company must, if that guess be an
approximation to the true facts, amount to £573 per day, or
89,700. per year.' These statements may serve to convey
some idea of the great extent of the omnibus traffic of Lon-
don, and of the number of persons dependent upon it; especi-
ally when it is remembered that the working of the horses which they refer constitute the working stock of only one
single route. The total number of omnibuses running to
and from the City of London is said to be nearly 200. The total number of stage-coach passengers running
and from London during the year ending January 4, 1845,
according to information obtained from the licensing office,
was 1472, of which it is calculated that at least 1400 were
ometuses. By a rough calculation, the writer to whom we are indebted for the collection of the facts, computes that about 2000, are spent daily in omnibus fares, making a total of 720,000l. per annum. The number of licensed drivers in May, 1844, was 1740, and of licensed conductors, 1859, but 300 took out licenses in both capacities, and are therefore counted twice. By adding these numbers to those quoted under HACKNEY-Coach, our authority computes (without, we may observe, deducting the 300 cases of licensing) that 8000 individuals were, in 1844, licensed as drivers and conductors of, or 'watermen' to attend to, the various public carriages used in the metropolis; that in all 3922 vehicles were in use, and that 'the census and course' of all the metropolitan hired carriages exceeds 1,500,000.' It is gratifying, as an evidence of the improving character of the class of men employed, to find that the above large number only forty-two were refused new licences on account of misconduct.

The length of journey run varies from about four up to twelve or thirteen miles; but by far the greater part of the London omnibuses run a total distance, from end to end of their journey, of less than eight miles. With such a usual charge is fivepence per passenger, whether for the whole or a part of the journey; but a very large portion of their receipts are from 'short' passengers, or such as are picked up and set down along the way. Omnibus proprietors are much exposed to peculation on the part of their servants, and various mechanical contrivances called 'tall-tales' have been tried to protect their interests by registering the number of passengers carried. They have continued in use; but it is in connection with the association system a method of checking the conductors, by a kind of secret police, has been adopted. When it is found that the returns made by one conductor fall short of the expected sum, spies are sent out who have continued in use; but it is systematic is this service performed, that any attempt at deception is sure to be detected, and followed by suspension or dismissal.

The power of applying such a check is one of the many advantages of the association system, in which, as commonly worked, each individual proprietor contributes a certain number of turn-out (a turn-out being the technical name for an omnibus with its complement of horses and men) to a common stock, which is worked, so far as regards the time of starting, speed, and other regulations, for the common benefit. The receipts of each omnibus are then paid into a common fund, from which each proprietor receives a portion proportionate to the number of turn-outs contributed and maintained, without regard to the actual receipts of the omnibus owned, by him.

The laws which relate to hackney-carriages and Metropolitan stage-carriages are chiefly comprised in two acts of Parliament, viz.: the 17 Geo. IV. c. 92, the 'Metropolitan Omnibus and Stage Carriages Act in the reign of William IV. in the year 1834,' entitled 'An Act to amend the Laws relating to Hackney-Carriages, and to Wagons, Carts, and Drays, and to place the Collection of the Duties on Hackney-Carriages and Post-Chaises and Post-Coach Horses under the Prosecution of the Commissioners of Stamps,' and G & 6 Vict. c. 86, (22nd August, 1843), entitled 'An Act for regulating Hackney and Stage Carriages in and near London.' In the former act are contained the greater part of the enactments which relate to hackney-carriages; in the latter, those which more especially apply to Metropolitan stage-carriages (omnibuses).

The limits of hackney-carriages (hackney-coaches and cabriolets) are five miles from the General Post-office, London; and drivers of hackney-carriages are comparable to drive five miles from the place where hired or from the General Post-office. Hackney-carriages shall be discharged at any place beyond the limits of the metropolis (that is, beyond a circle of which the radius is three miles from the General Post-office), after eight in the evening and before five in the morning, and may be driven by a man nearest station or in the said limits or to any standing-place beyond the limits where the carriage may have been hired, at the option of the hirer.

The fares of hackney-carriages are fixed by the act 1 & 2 Wm. IV. c. 42. For every hackney-carriage drawn by two horses, for any distance not exceeding one mile, 1s.; for any distance exceeding one mile, at the rate of 6d. for every half-mile, and 4d. for every quarter of a mile. The maximum number of any half-mile completed. By the time, the fare, is for not exceeding thirty minutes, 1s.; not exceeding forty-five minutes, 1s. 6d.; not exceeding one hour, 2s.; and for any further time at the rate of 4d. for every fifteen minutes completed, and 6d. for any fractional part of fifteen minutes. The fares for hackney-carriages drawn by one horse (cabriolets) are one-third less, so that for the first mile they are 5s., for a mile and a half 6s., for an hour 9s., and so on. Any hackney-carriage is licensed for any one of these purposes, and also for any one of the others.

Every hackney-carriage and Metropolitan stage-carriage is licensed by a registrar, deputy-registrar, or other officer appointed by one of His Majesty's principal Secretaries of State; and every person who drives or conducts a hackney-carriage or a conductor of a metropolitan stage-carriage, and every waterman, at the time of granting the licence receives a metal ticket, which every such driver, conductor, or waterman is bound to wear or cause to be worn by him, and which may be distinctly visible. Watermen are the assistants of drivers of hackney-carriages and of Metropolitan stage-carriages stationed at certain places to supply the horses with water, &c., and they also receive a licence. A stamp duty of 6s. is charged on every licence, and 10s. a week during the continuance of it. Plates are to be affixed to hackney-carriages with the name and abode of the proprietor and number of the licence; and 'Metropolitan Stage-carriage,' or such other words as the registrar shall direct, are to be painted on omnibuses. Proprietors of metropolitan stage-carriages fix their own fares, but those fares are to be distinctly painted on or in the omnibus, as well as the number of persons for whom the carriage is licensed.

Hackney-carriages standing in the street, though not on any stand, to be deemed plying for hire. Drivers may ply on Sundays, and in the two days in the week preceding a Bank Holiday, for the purpose a driver to watch him by taking their places as passengers, and reporting at headquarters the numbers taken up, as a check upon them; and so systematically is this service performed, that any attempt at deception is sure to be detected, and followed by suspension or dismissal.

The act 6 & 7 Vict. c. 86, repeals a previous act (1 & 2 Vict. c. 79), and extends the enactments not specifically repealed of the 13 & 14 Wm. IV. c. 22, to the 6 & 7 Vict. c. 86. Other provisions of the acts relate chiefly to the restoration of property left in carriages, to furiously driving, intoxication, insulting language, loitering, and other acts of misbehaviour; to proceedings of proprietors, drivers, and conductors, as to licences, payments of duties, contracts with each other; and to modes of granting summons, powers of magistrates, punishments, &c.

METROSIDEROS (from μπρός, the heart of a tree, and σιδήρος, iron), a genus of plants belonging to the natural order Myrtaceae. It is distinguished from allied genera by the tube of the calyx not being angular, adhering to the ovary, the limb 6-lobed; the stamens 20-30, free, very long, and exserted; the style filiform, and stigma simple; the capsule 2- or 3-celled, the cells many-seeded; the seeds wingless.

The species are native to Madagascar, and a species is found growing near Sydney, in New South Wales.

M. vera, true Iron-wood, has opposite ovate-lanceolate acuminate quite glabrous leaves seated on short pedicles; the cymes axillary, pedunculate, many-flowered. It is a native of Java and Amboyna, among rocks. The Chinese and Japanese value the wood of this tree, which they apply to many purposes, as the making of rudders, anchors, &c. for their ships and boats. The bark is used in Japan as a remedy in mucous discharges, diarrhoea, and dysentery. It is usually mixed with some aromatic, as parings, cloves, or nutmeg.

M. polymorpha has opposite coriaceous leaves, of various forms, glabrous on both surfaces, but covered with a little silky tomentum on the lower; the flowers are perfect, in terminal and axillary, corymbose; the calyxes and bractlets glabrous or clothed with silky tomentum. This species is a tree, and grows in the Sandwich Islands, and is said to be the plant from which the clubs of the native people are made and employed in warfare by the South Sea Islanders. The Aki or Limgun Vite of New Zealand, the Rata and the Pohutukawa of the same country, are all allied, the seeds trees belonging to these species. (Lindley.)

Several other species of Metrosideros have been described, natives of New Holland and the South Sea Islands. M. incisa, a beautiful shrub, is found growing on the South Island of New Zealand, and is called the 'Alpine Labrador. As far as the Islands, it is in 50° south. The M. burzillii of Allan Cunningham is the New Zealand plant called Ahu, and is a rambling shrub, adhering to trees, and climbing by means of its lateral
root to the summits of the loftiest trees in the forests of Wanganaroa and the Bay of Islands. In cultivation these plants may be grown in a mixture of loam, peat, and sand. They consist of thirty-three pictures and the following cutting. Hips cuttings will root in sand under a hand-glass.

(Don, Gardener's Dictionary; Lindley, Vegetable Kingdom: Barnett, Outlines of Botany.)

MEYER, GABRIEL, one of the most celebrated of the German engravers of Bonn, where he was born in 1755. He studied under Bartolozzi, in London, and remained altogether about twenty years in England. He published in 1790 a set of thirty-three engravings, including the title, after Goethe the Third's collection of drawings by Parmeggiano; and in 1791 a set of sixty-three plates in a similar style, after the designs by Polidoro da Caravaggio, in the possession of Sir A. Hume, He published a great number of imitations of old masters. In 1801 Metz went to Rome, and commenced a series of engravings after the Last Judgment in the Sistine Chapel, by Michael Angelo. It is engraved in chalk manner in Silesian separate sheets, with an outline of the whole. Metz died at Rome in 1827, aged seventy-two. Dr. Nagler enumerates upwards of two hundred of his engravings in his Künstler-Lexicon.

MEZI, GABRIEL, one of the most celebrated of the Dutch painters, was born at Leyden in 1616. It is not known under what master he studied, but he obtained a great reputation at Amsterdam while still young. Like Mierts and Terburg, Mezi painted landscapes, and was particularly noted for his pictures painted what are called conversation pieces; and often a lady at her toilet, or in her boudoir, with all the usual accessories; his scenes are occasionally taken from humble life, but generally represent the higher classes of the community. He excelled in light and shade, drawing, and colour, and his execution is always extremely careful: his pictures, though very small, are always finished with the minutest attention to detail. Metz perhaps attained perfection in his style, and can be counted among those few inferior artists of the 17th century who can claim to have raised the not inconsiderable art to its highest degree of excellence: the tone of his pictures is complete nature, every tint is perfectly true, and every object is accordingly in its proper place, for his drawings and his line, perspective was equal to his light and shade, and colour. Beyond this he did not go; his works exhibit nothing choice or extraordinary either in subject or arrangement; and the faithful representation of familiar life appears to have been the end of his art, not for the sake of the scenes, but for the imitation of his. He was essentially a materialist in art, and this is the distinguishing characteristic of the Dutch painters generally. He painted a few portraits; there is one of Admiral van Tromp in the Louvre. Some of his works realize very high prices; many of them have been engraved. Mezi died, according to D'Arsenville, in 1688, in consequence of undergoing an operation for the stone: thus it appears that Mezi died in Munich, the city of his birth, by him, dated 1682; the date therefore of his death is uncertain.

MEUM (from miurus, smaller), a genus of plants belonging to the family of the labiatae. It is a small genus of about a dozen species, which are all prostrate herbs, with small white flowers, and small teeth. It has an oblong calyx; entire elliptical petals, acute at both ends, with an incurved point; the fruit elliptical, terete, or slightly dorally compressed; the carpels with five sharp somewhat winged ridges; the stamens and cumminae with many veins. There are two species of this genus.

M. Aethamasticon, Common Bald-Money, has bipinnate leaves with multipartite leaflets, the segments thread-shape, acute. This is a highly aromatic plant, with numerous white and yellow flowers. It is a native of Europe, in dry mountain pastures, and is found in England and the mountains of Scotland. The roots, seeds, and every part of the plant are aromatic. It contains a number of volatile oils, and, as stomachics and carminatives. This and the other species, M. Mutellina, the Swiss Bald-Money, which is a native of the subalpine pastures of Europe, enters into the composition of the compound called Venemie treacle.

(Rhabdina, Manual of British Botany; Lindley, Vegetable Kingdom.)

MEYER, HENRICH, a German designer and painter, and a son of the above, was born in 1787. He is known as Goethe-Meyer, from his close intimacy with the great writer. For forty years Meyer was Goethe's consulting and confirming oracle in all opinions on art, and was every day at his side in the critical parts of Goethe's publications on art, as Kunst und Alterth., 'Winkelmann und sein Jahrhundert,' Propylachsen, &c.

P. C. S., No. 123.
deep gorges in their sides and frequently cause landslips. The lower part of this tract contains numerous vineyards, orchards, and orange plantations. Between the two largest places of the island, Ponte Delgada and the southern town of and Ribeira Grande, on the northern, lies the lowest part of the whole. The shores are here low, and rise almost imperceptibly towards the interior, where an irregular line of hills and craters, beginning on the east, with the Fico do Fogo, 1031 feet above the sea, and terminating on the west with the Sierra Gorda, 1574 feet. The soil of this tract is in general very fertile, but there are extensive plantations of vines and vitreous lava, which are only fit for vineyards. There are no hot springs or other signs of subterranean heat, and the whole of this district is deficient in water, in consequence of its inferiority. The most western part of St. Michael’s appears to have been more subject to volcanic changes than any other. It contains in its centre a valley of an elliptical form, called the Sete Citades, which is three miles long from south-east to north-west, and two miles and a half broad from south-west to north-east. The ridge which bounds it is of nearly equal height throughout, except where it runs into peaks. On the south-east is a short chain, two miles long, terminating in the Pico de Carvoa, which is 2652 feet above the sea. The greater part of the interior of this valley is occupied by two lakes. In this tract are two hot springs which rise up in the sea below high-water mark. The soil varies much in character, being in some parts a yellow argillaceous earth, well suited for cultivation and of great fertility, in others a mixture of pumice and scoria, or a vitreous intractable lava which defies the efforts of even the most assiduous agriculturist. Hot springs are frequent, except in the eastern districts and the country between Delgada and Ribeira Grande.

Although the climate is variable both as to heat and humidity, it is generally temperate, and the climate does not materially affect health or comfort. In summer, the sun generally glistens in the atmosphere and mitigates the heat; in winter, there are few days when heat is not felt, and during the whole year there is only one day in which agricultural labour may not be carried on.

The mean temperature in winter is 62° and in summer 69°.

The extremes of the whole year are 46° and 64°, in winter 46° and 76°, and in summer 65° and 84°. In February 46° and 72°, and in August 65° and 84°. A much greater proportion of vapour exists in the air in all seasons than in England. The mean annual quantity of rain is 30 inches near the level of the sea, and the maximum 42 inches, while it is probably not less than 60 inches on the mountains. The prevailing winds are from the north-east and north-west. Northerly and easterly winds prevail over those from other points of the compass in the ratio of 57 to 26, which indicates that the island is not situated in the part of the Atlantic where westerly winds generally prevail.

The principal occupation of the inhabitants is the cultivation of crops and the grazing of animals. The island contains 147,200 acres, of which 2100 is forest and 102,600 acres are occupied by mountains, lakes, rivers, roads, and dwellings. The grazing which is extensively cultivated, is especially in the west, Indian corn, and beans. Yams and bananas succeed in several places on the southern coast. Several kinds of vegetables are grown, but the common people cultivate only corn, potatoes, and tobacco to any extent. As two-thirds of the island are cultivated, the produce-grounds on the more rugged portions of the island are extensive. All the domestic animals of Southern Europe are kept, but the breeds are inferior. Of wild quadrupeds only rabbits, ferrets, and weasels are noticed, with rats and mice. There are many kinds of birds, mostly those of small size; fish is rather abundant along the shores.

The inhabitants, who are Portuguese, are an industrious people, but near the whole of them, amounting to 80,000 individuals, are employed in agricultural labour. With the exception of the common mechanical trades, the manufacturing industry is limited to some coarse woollen stuffs, especially rugged and coarse, a coarse kind of red pottery, which is made at Villa Franca.

The capital of the island, Ponte Delgada, is built on the southern shore. It has an unsafe harbour, for when the wind turns to the south all the vessels are compelled to slip their anchor, and they can only return after the wind has changed to another quarter. The town is surrounded by extensive grape plantations, and is rather a pleasant place, in which many English live. The population is upwards of 20,000, and it is the largest town in the Azores. Alagoa, farther east, has a small port and 4000 inhabitants; and Villa Franca, still farther east, 5000 inhabitants. In the vicinity of these places are extensive plantations of oranges. On the northern coast is the town of Ribeira "Grande, with 12,000 inhabitants. It has no harbour, being hewed in by rocks of rock, which run out some distance from the shore. It is irregularly built, the houses being scattered over rocky uneven ground, and forming narrow irregular streets along the coast. It has some manufactures of woollen stuffs.

The foreign commerce was formerly confined to Portugal, but at present the island is visited by English, American, and Brazilian vessels. The number of English vessels which anchor annually at St. Michael’s is usually 120, and the trade is frequent, except in the eastern districts and the country between Delgada and Ribeira Grande.

Although the climate is variable both as to heat and humidity, it is generally temperate, and the climate does not materially affect health or comfort. In summer, clouds generally float in the atmosphere and mitigate the sun’s heat; in winter, there are few days when heat is not felt, and during the whole year there is only one day in which agricultural labour may not be carried on.

The island was discovered in 1444 by Cabral, and was settled in the following year. Since that period it has remained in possession of the Portuguese.
picture, on which their names were inscribed. This circumstance is noticed by Pausanias, who remarks also that the best part of these paintings was Acacius and his horses. It is observable that all Micon's pictures were of such subjects as admitted the themes of horses, as the horse was not the best subject that could be chosen for the display of the painter's skill in painting these animals, as the battles of the Amazons and the Centaurs. Micon, as already mentioned, was the most celebrated of the Greek painters in his respect, yet he was not altogether perfect in his horses, for he gave some of them lashes to under their eyelids, which horses have not. His horses were objected to on this account by the scientific horse man and a critic, and who, according to Pliny, was the first writer on Equitation: a statue by a sculptor of the name of Demetrius was erected to Simon's memory at Athens. This nicety of criticism tends rather to establish Micon's reputation than otherwise, as this was the only error detected by so able a critic. According to another account, it was a fault that was found with some of the horses of Apelles. Great excellence however, in the drawing of the horse, is not at all inconsistent with the state of the art at the time that Micon lived, for we have actual remains of that very period in the beautiful horses of the frieze of the Parthenon, now in the British Museum, executed under the superintendence of Phidias, who was the uncle of Paniasus, with whom Micon worked in the Focce.

A figure in one of Micon's battles of a certain Bute was the origin of an Athenian proverb: Bute was painted conceitedly, and it compelled him to relinquish painting pictures, for it was his head and eyes, which seemed to the Athenians so very expeditious a method of painting a warrior, especially one it was necessary to give a name to, that 'Micon painted Bute's eyes out of place', which was the common saying of expressing anything that was quickly done. Varro speaks of the style of Micon as crude and unfinished when compared with the works of Apelles and later artists. This is very possible, and the same might be said of many of the works of Michelangelo and Raphael compared with those of almost any of the scholars of the Carracci; yet the difference is not one of execution, and is not at all essential, nor does it in the least interfere with the higher qualities of art, as form, expression, or composition.

Micon was also a sculptor: he executed, according to Pausanias, the statue of Callias, the Athenian pacificist, at Olympia. Micon appears to have been not an uncommon name among Greek artists. The father of Onastus of Aegina was Micon; and Pliny mentions Timarete, herself a painter, as the daughter of a painter of the name of Micon.

There was also a Syracusan sculptor of the name of Micon; he was the son of Nicestes, and made the two statues of Hiero II., which were placed by the sons of Hiero at Olympia.

MICROMETER. [Divided Eye-Glass Micrometer, P. S. C.]

Mierevelt, Michiel Janzen, a celebrated Dutch portrait painter, was born at Delft in 1607, not in 1668, as in the first edition of Van Mander. His father was a goldsmith. Mierevelt was a very precocious boy; at eight years of age he could write better than any schoolmaster in Delft; at twelve he could engrave, and at fourteen he was a good painter, having studied for about two years under Anthony Bloklandt at Utrecht.

Mierevelt painted almost exclusively portraits, and chiefly historical portraits of that celebrity, even beyond the limits of his own country, and he could not be persuaded to leave it. The Duke Albert of Nassau, in consideration of his abilities, granted him the privilege of carrying on his Meissonier worships, and then, and Charles I. of England invited him in 1625 to visit England, an invitation which Mierevelt declined because the plague was at that time in London. He died at Delft in 1644.

Mierevelt's portraits, though extremely numerous—Houbrecht compiles them at 5000—are generally well drawn and very elaborately finished. Many of them are engraved by various masters, and there are rare drolleries, which the great landscape painter, Jan Michiel, was of the same age but lived longer. He had two sons, who were likewise excellent portrait painters, Pieter Michiel and Jan Michiel; the elder was born in 1609, and died aged only twenty-eight in 1633: the younger also died young.

The following verses are under Mierevelt's portrait in the first edition of Van Mander, which was published during his lifetime:—

Penguendo su vivum, quo non presentior alter; Deum, qui non est tecum, tuae sunt virtutis.  
Principum magna fortitiae atque: is ipse  
Hic est, qui scelus et armas multae cuita.  

(Van Mander, Het Leen der Schilders, &c., ed. 1674;  
Houbrecht, Groote Schouburg der Nederlandsche Konstchilzens ed.)

MIGLIARA, Giovanni, a very distinguished modern Italian artist, who invested architectural painting with a species of interest which it had not before possessed even in the ablest hands. He was born at Nice on October 15th, 1785, of poor parents, who placed him with Luigi Zucolfi of Milan, to learn wood-engraving; but on discovering his strong and peculiar talent, Zucolfi sent him to study architecture and perspective, under Albertolli and Levati, at the academy of the Brera. So prepared, he next studied scenic painting under Galiari, and practised that branch of art—for which Milan was then celebrated beyond any other place in Europe—about eight years, 1809-10, sharing in the fame reaped by Galiari, Peregno, Landriani, and Sannquirzico. This eminently successful career, one moreover which he pursued with such devotedness, was all at once arrested by a long and dangerous illness, occasioned partly by over-exertion, and partly by a pulmonary attack in consequence of cold caught while working in a damp place. This perhaps eventually proved a great advantage both to himself and to art, inasmuch as it compelled him to relinquish painting, at least in the smaller scale, and led him to produce works that are now treasured up for admiration in galleries. At the time however his illness was a serious calamity, for his family were reduced to very great distress. Owing to some care and a portion of money he received, he was gradually recovered, and no sooner did he begin to do so, and was able to sit up in bed, than he employed himself in making pictures on a small scale of the various scenes—amounting to about a hundred—which he had painted for the theatre. Produced through necessity, as the only means of earning subsistence for himself and family, these subjects not only found purchasers, but there became even a demand for them. Thus encouraged he determined to undertake the decorating of scenic scenery 'in small,' and also to combine the dramatic with the scenic-painter, peopling his canvases not with mere figures as accessories, but with episodical groups of actors, either illustrating popular and local manners, or recording some historic incident; and among his numerous pieces of the latter class may be mentioned his Ileegonda, Adelaide dying in a souterain of the Trappists, the Condemnation of Pansa, the Duchess de la Vaillere, and Charles V. at a Convent. In depicting the personages and manners of familiar and everyday life, he displayed a vein of strong humour; and his converted to the uses of a popular poet, and his dialect poems, rendered him an especial favourite with the public. Independently of the figures and stories—the great attraction for the many with which he:bold his productions—he converted architectural painting into a more actual portraiture of buildings into real picture, by the united mastery of perspective, chiaroscuro, and colouring. His pictures give the impression and sentiment of the edifices themselves, and are stamped by illusion yet anything but prosaic reality. Such was the reputation he acquired, that not only the King of Sardinia bestowed upon him the Order of Merit, but his native city Alessandria struck a medal in honour of him, in 1829. Honoured and prosperous in his profession while only in the meridian of life, he might, not unreasonably, look forward for years of uninterrupted happiness, when he was carried off by an attack of fever, which prevailed at that time, on April 19th, 1837. He was followed to the tomb by the academicians, artists, and others to the number of upwards of three hundred; and his last work, his unfinished fresco of St. Marco, was brought to the procession. His daughter Teodina practices as an artist, in subjects of the same kind as her father.

(Giuseppe Saccii, in Tipaldi's Biografia; Westminster Rev., vol. iv.)

MIKANIA, a genus of plants belonging to the natural order Compositae, to the suborder Tubuliflorae, to the tribe Eupatoriacese, and the subtribe Adenostylaceae. It has a thorny stem, some hairy, some not; the leaves divided, with a branchlet at the base or below it; the tube of the corolla short, with the throat dilated and somewhat campanulate; the anthers somewhat protruded; the achene angular; the pappus in 1 row, rough and hairy.

2 Q 2
M. officinalis has an erect, smooth, nearly simple stem, with leaves decussating somewhat triangular-ovate, coriaceous with a greenish tinge on the sides, smooth and glabrous, drooping; the pinnules corymbose and terminal. This plant is a native of Brazil, where it is called Coraço de Jace. It is a handsome plant. The leaves contain a bitter principle and are used in the treatment of the same diseases as the Cascara and Chincha barks. They are said to be an especially valuable remedy in remedying fevers and in atonic dyspepsia. They are administered in the form of a tincture.

M. Guaco, Guaco plant, has an herbaceous twining stem; the branches round, sulcate, hairy; the leaves stalked, ovate, somewhat acuminate, shortly narrowed at the base, remotely toothed above, hairy; the axils axillary, stalked; the heads somewhat tertane sessile; the bractlets linear, shorter than the involucres; the involucral scales linear-oblong, obtuse, downy; the echinace smooth. This is one of the plants called Guaco in South America, and is used both internally and externally as a remedy against the bites of poisonous serpents. This plant is cultivated by the Indians for the purpose of being used. It is easily known from other plants by the large indigo blue spots that mark the under surface of its rough leaves. It is probable that the spotted character of the leaves of this and plants similarly employed, as the Cithamunorum and a species of Aristolochia, is due to their being fed on by certain species of poisonous snakes. ‘The mode of using this remedy,’ says Poppug, ‘is very simple; the wound is somewhat distended, and the fresh-pressed juice is dropped into it; the surrounding parts being wrapped with the leaves, and the juice also taken by the mouth. The tincture, made with common brandy, is also much celebrated, and recommended to travellers as a secure and portable means of cure. In Guayaquil little cakes are formed out of the fresh-pressed leaves, which, when dried in the sun, retain their activity a long time. The effect of the Guaco is not in all cases alike quick and decided; but observations, both in Maranon and Ega, prove that very often the wound is immediately closed, the pain vanished, and, with the exception of little ulcers, the cure had been effected. In Venezuela, and especially about Mucuchies, every year several persons are bitten by snakes; but the Guaco had acted so efficiently that in the memory of man only two children were known to have died of such wounds.’ Although Poppug has given so favourable an account of this remedy, he says in another place that ‘the excision and cauterisation of the wound immediately after it is received is undoubtedly the safest plan.’ Besides the guaco there are several other plants used in South America, some of which are called guaco, as the Herpetes colubrina, Dorstenia tubicina, Aristolochia cyanophylla, &c. The guaco has been tried in this country as a remedy in hydrophobia, but without success. The Uralli, or snake-poison of Brazil Guiana, is compound, and contains in it strychnia. [Stachys, P. C.]

M. opaca is a smooth climbing plant, with an angular stem; it has stalked, coriaceous, repand-toothed or nearly entire leaves, when full grown rather blunt; the heads stalked in corymbose panicles; the involucral scales oblong, rather acute; the bractlets lanceolate; involucre rather shorter. This plant is a native of Brazil, where it is called Eruc du Cebia. It is also employed against the bites of snakes, and is said to effect a cure by its powerful diuretic action. An account is given of this plant by Gomez in the Memoirs of the Royal Academy of Lisbon for 1812, where it is described as the Eupatorium crepatum.

The genus Mikania is closely allied to Eupatorium, and they belong to a group of plants in the order Compositae, the most remarkable for their activity. Dr. Linley states, in his Vertebrates, that the tribe Mikania is the most important in the production of Eupatorium glutinosum, and not of Artanthro elongata, as has been usually supposed. Of this plant Mr. Hartwig says, in a communication to Dr. Linley, ‘Matico is the Eupatorium of the guerras of Chiapas and Yucatan, a species of Eupatorium glutinosum, or the Chusullangas in the Quichua language. It forms a shrub 3-5 feet high, and is common in the higher parts of the Quichua Andes, where its properties were used by the Indians, who called it Matico. It is better known under his nick-name Matico (little Matthew), who when wounded in action applied occasionally the leaves of some unknown plant, which had the immediate effect of stopping the bleeding. A shrub frequently used to be the Chusullangas, which has since been called, in honour of its discoverer, Matico. That it is the true Matico of the inhabitants of Quito and Riobamba I have not the slightest doubt; it is a plant, to my mind, not only valuable to myself, and upon comparing the latter with Kunth’s description I found them to agree exactly with his Eupatorium glutinosum. The Matico has been used in Europe, and is said to be an important remedy in stopping the bleeding from small wounds.

(Poepigg, Reise in Chich, Peru, &c.; Lindley, Vegetable Kingdom; Lindley, Flora Metea.)

MILITARY DISCIPLINE. We have little knowledge of the manner in which offences against military discipline were punished by the Greeks; but it appears that, for sedition or mutiny, the commander of an army had the power of putting any man to death. The mutiny took place partly in consequence of the jealousy excited by the favour which he showed to the Persians, caused thirteen of his Macedonians to be executed without a trial. (Arrian, Anul., viii. 8.) The military law of Athens prescribed the punishment of death for the crime of desertion while on service; yet occasionally, for this serious offence, the party was only imprisoned or sentenced to pay a fine. Whatever might be the power of an Athenian commander over his soldiers in the field, it is probable that he would only have recourse to very severe punishment in the case of the termination of a campaign, a man who might consider himself unjustly treated could compel his officer to answer for his conduct before a tribunal of his countrymen. Among the Macedonians, but especially the detachment of the troops which was left to guard and garrison Sestos, the extreme penalty was, when at home, to wear a party-coloured dress, and be obliged to submit in silence to any insult which the master of the house chose to offer. A grace also fell upon the soldier who, in action, had the misfortune to lose his shield.

The Romans punished crimes committed by the soldier with great severity. For the greatest offences soldiers were beheaded or crucified; and under the Pagan emperors some, probably such as professed the Christian religion, were burnt alive or exposed to wild beasts. On the occurrence of a mutiny, every tenth, twentieth, or hundredth man was sometimes chosen by lot, but generally only the ringleaders were selected for punishment. Deserters and seditionous persons were frequently, after being scourged, sold for slaves; and occasionally the offender was made to lose his right hand, or was beheaded nearly to death.

If a soldier absented himself from the spot assigned to him for the night-watch, or if he was found asleep at his post, he was the next day brought before the tribune, who having heard the evidence, on the fact being proved, sentenced him to suffer the utmost. It appears from Polybius (vi. Ex. 2) that the tribunes had the power of very greatly touching or even killing any soldier who was proved to be a traitor. The court of the staff as a signal, the persons appointed to inflict the chastisement fell upon him and struck him repeatedly with sticks or stones, frequently with such violence as to cause his death: the culprit was allowed to escape by flight if able; but in this case, he was never permitted to return to his country, or, if he did return, no person dared to afford him shelter or relief. Punishments of a like nature, but less severe, were inflicted upon a soldier who was guilty of theft, or of giving false testimony either in his own favour or against a comrade. For certain breaches of discipline the offender suffered a temporary deprivation of his pay, the forfeiture of his arms, or degradation from his rank. Sometimes he was sentenced to remain outside of the camp exposed to the chance of being taken by the enemy, or he was made to stand for a certain time in an unmilitary dress before the praetorium. In some cases it was made a capital punishment. In some cases, the exchange into a corps of inferior rank, or to be entirely dismissed from the service with disgrace. Punishment was also inflicted on a soldier for cowardice for losing his head. Among the nations of modern Europe the punishments for military offences were, till lately, no less severe than they
were among the Romans. Besides the infliction of a certain number of lashes with cords, soldiers convicted of theft, marauding, or any other breach of discipline which was not punishable with death, were sentenced to run the gauntlet as a punishment. It may then be considered that the regiment was drawn up in a double line; and each man being furnished with a small stick, generally of osier (except the grenadiers, who used their belts instead of the sticks), the culprits, naked to the waist, was either marched slowly or allowed to run as fast as he could, according to circumstances, from the head to the rear extremity between the two lines, each man striking him as he passed along. In certain cases that of the grand assault, a movement, and sometimes also from the town or district with a charge never to appear there again under pain of death. The punishment of the knout, in the Russian army, consists in the naked back of the offender being struck with a leather belt.

Cavalry soldiers were frequently punished by the picket, as it was called; this consisted in the man being made to hang by his hands from a beam during a certain time, a stake with its upper end made sharp being planted in the ground under him; so that, when from weariness he could no longer keep himself up, his foot was pierced by the stake: this kind of punishment has been long since abolished.

It happened that many of the soldiers, being goaded to madness by the severities exercised on them, either from caprice or from a mistaken opinion that strictness in the minutest details of discipline is as necessary as in points of the highest importance, considered the soldiers, who were considered as tyrants, and have afterwards, apparently without regret, suffered death for the crime.

Confinement in a dark room during a certain number of hours was a common and distinguished officer to have his absence without leave from parade, either on account of drunkenness or from any other cause, and soldiers so offending were formerly made to stand or rather to revolve in a cage or pillory which continually turned on its axis.

Besides the punishments of death and transportation, which, for great crimes, are within the scope of military law, in the British army, breaches of discipline are visited by flagellation, temporary imprisonment, that is, loss of pay, demerit, and the deprivation of certain privileges, that is, the performance of fatigue duties; but the punishments which consist in confinement to barracks and laborious employments, continued during long periods at the discretion of commanders of regiments, have been abolished by an express order from the present commander-in-chief.

While an army is in the field it is evident that breaches of discipline should be punished with extraordinary severity, and that the punishment should follow almost immediately on detection. It might be presumed that acts of treachery will seldom be committed; but unfortunately desertsions to the enemy frequently take place; the more usual crime is howe
ter, that of outrages on the inhabitants of the country, a circumstance which is generally accompanied by gross acts of violence, often murders, committed on the defenceless people; and no doubt can exist that soldiers guilty of such crimes should be subjected to the severest penalties. Even when the crime is less heinous, the well-being and peace of the safety of the army may be perilled in consequence of the spirit of resentment induced in the inhabitants of the country by injuries inflicted on them; such disorders should therefore be repressed by making signal examples of the offenders. It may be said also that the vice of drunkenness in soldiers deserves, in general, the heaviest punishment: the miscarriage of an enterprise, and defeat, with the loss of numbers of gallant men in an action, may be the fatal consequences of a failure, from inebrity, in the delivery of a report or order. That of a gun is the greatest crime, and the punishment of an offender should be if possible immediate is also evident: the army may change its position or cantonments, when, if any delay takes place, it may be impossible for the necessary orders to be carried out. For these reasons, the same crime is punished by the accidents of war. A long interval between the commission of a crime and its punishment diminishes the fear of the latter by opening to the culprit another chance of escape. But in those events, the sentence be
ing a warning: the impression produced by the crime wears off, and the punishment assumes, in some measure, the appearance of an act of cruelty. The circumstance that an army in a time of peace and in a time of war, or rather when in the presence of an enemy, are very different: in the former case soldiers have no opportu

MILITARY TENURES. [FREEDOM, F. C.]

MI'LLIUM, a genus of grasses belonging to the tribe Agrostidieae. It contains only one British species; the meadow-grass, which is a common, low-growing, diffuse panicle, with acute Spikelets, smooth, a stem, and linear-lanceolate leaves. It has a stem 5 or 4 feet in height, and is found in damp shady woods.

(Millinton in The British Botany.)
MILLINGEN, JAMES, a very eminent English archaeologist, was born in London, on the 18th of January, 1774. His father, who was a Dutch merchant, placed him at an early age at Westminster School; the boy showed a great partiality to everything connected with ancient coins, having frequent opportunities of seeing a good collection in the house of one of his father’s friends. His principal study in his leisure hours was the science of war, and he was anxious to enter the army in the event of the country being at all protractive. In the autumn of 1793, his father determined to send him from Westminster to one of the universities. However, the French revolution, which broke out at the time, changed his plans, for Millingen’s father was a bad talker, and his new pursuits were not to his taste; he devoted all his leisure hours in the study of such works as Vaillant, Beauvois, Pinkerton, and Polybius, and his savings were spent in the purchase of ancient coins, of models of cannon, projectiles, and other materials of war, until after some time he obtained an employment better suited to his pursuits, and was appointed to the mint. In this capacity he became acquainted with several men of distinction and archaeologists, among whom we may notice the Abbé Bartholdy, brother of the well-known author of the ‘Voyage du Jeune Anchareis en Grèce,’ the geographer Barbé du Bocage, Walckenaer, D’Aumont, and others. The habit formed in such company, however, were not of long duration, for when the National Convention ordered the confinement of every British subject until the peace, the young archaeologist was arrested in the dead of night, and was constrained to leave his native country. He escaped incarceration, but he was ordered to quit Paris under the surveillance of the police. In the Prison des Ecossois James Millingen became acquainted with Charles Esté and Sir Robert Smith, who after their liberation established a banking-house at Paris, in which James Millingen became a partner. Shortly afterwards an event occurred which opened the way to Millingen’s wide field of speculation. Some labourers, who were working near Abbéville, discovered a Roman entrenchment, and dug up several earthen vessels filled with gold coins of Roman emperors down to Septimius, Severus, Caracalla, and Geta. Most of them were in a most excellent state of preservation, and some of them were extremely scarce. Millingen purchased them at the value of their weight, and soon after disposed of them in France and England to great advantage. From various circumstances this house in which Millingen was a partner failed, and he was thus thrown upon his own resources. His perfect knowledge of coins and the relics of ancient art had in the meantime made his name known throughout Europe, and he would not have retired to England, but his well-proportioned constitution rendered it necessary for him to reside in a southern climate, where he enjoyed comparative good health. During the last twenty-four years of his life he resided in Italy; at first in Rome, and latterly in the city of Florence. He made occasional visits to Paris and London, where his arrival was always hailed by archaeologists, as he was considered one of the best critics of that ancient art. In 1845 he resolved to return to England, with a view of settling in London, when he was attacked by a severe catarhal affection. At first he thought little of his illness, and wrote several letters even the day before his death, but on the 1st of October he died without a struggle, at the age of seventy-two, more from the effect of exhaustion than of disease.

What Millingen has done for practical archaeology is of the highest importance for the sciences, and work was also published by the author in French. 4, ‘Antient Coins of Greek and Cities, and Kings,’ London, 1821, 4to., with figures; 5, ‘Antient medals and Monuments of Greece, and Art,’ London, 1822 and 1826, 2 vols. 4to.; 6, ‘Remarks on the State of Antiquity in the Roman Provinces,’ London, 1831, 8vo.; 7, ‘Syllago of Antient Unedied Coins,’ London, 1837, 4to. with figures; 8, ‘Considerations sur la Monnais’ de l’Ancienne Itale,’ and a supplement, Florence, 1844, 8vo. Besides these great works, there are a considerable number of essays on antiquities subjects by Millingen, in the ‘Annales’ and the ‘Bulletino’ of the Archaeological Institute of Rome, and in the ‘Transactions’ of the Royal Geographical Society of London.

CLASSICAL MUSEUM, part xi. p. 91, &c.) MINERALOGY. It will be seen by the number of substances now added under this head, that mineralogy has made considerable progress of late years. To the new substances which have been discovered, and which are now described, are added some which had before accidentally escaped insertion. In various treatises on mineralogy there will be found descriptions of some bodies which we have not omitted to notice, and in those cases it is to be considered that the substances did not appear to possess the novelty ascribed to them, or had been previously described by other names. We mention this as a general rule, though we are not without apprehension that minerals may by mistake have been omitted which ought to have been inserted.

ALUMINA, Sulphate of, occurs in crystalline efflorescent masses. Colour white, occasionally yellowish. Translucent. Lustre silky. Taste similar to that of alum. Very soft. Specific gravity 1.66. Found at Arya near Cumanas, and near Calama in Bolivia. Analysis—Sulphuric acid, 36.4; alumina, 16; water, 46.6; peroxide of iron, 0.4. Dr. Thomson’s analysis gives 2.26 per cent. of soda.

ALMONDITE occurs in thin laminae and in thin lamellae. Specific gravity 2.94. Found at Chardesford near Penig in Saxony, and at Arendal, Norway. Analysis—Boric acid—Phosphoric acid, 54.12; alumina, 38.36; lithia, 6.92.

ANHYDRITE (Anhydrous Sulphate of Lime) occurs massive and crystallized. Primary form a right rhombohedral prism. Cleavage very distinct parallel to the terminal planes and their two diagonals; parallel to the lateral planes indistinct.
MIN

Fracture uneven. Colour white, bluish, violet or reddish. Streak greyish white. Lustre vitreous, peary on the cleavage surfaces. Hardness 3-3 to 3.5. Transparent, translucent.

Refraction double. Specific gravity 2.9- to 2.9-9. Massive variety amorphous. Found at Halle in the Tyrol, Bex in Switzerland, and in the salt-mines of Upper Austria and Salzburg, &c. Analysis of a specimen from Aus: Sulphur, 67; lime, 43; silica, 3.

AMORPHITE occurs crystallized. Primary form a rohdohedron. Cleavage parallel to the primary planes. Colour white, sometimes yellowish or brownish from an admixture of oxide of iron. Fracture uneven. Hardness 3 to 4. Lustre vitreous. Translucent. Specific gravity 2.9 to 3. Found in Salzburg and in the Alps, &c. Analysis, by Berthier: Carbonate of lime, 51.2; carbonate of magnesium, 25.7; carbonate of iron, 20.9; carbonate of manganese, 3.5 to 99.8.

ANHIDROITE occurs crystallized. Primary form a doubly oblique prism. Colour white. Streak white. Fracture conchoidal. Hardness 6-9. Lustre vitreous, inclining to peary on the cleavage faces. Translucent to transparent. Specific gravity 2.9-5. Found in Montes Semnos. Analysis, by Bose: Silica, 44.9; alumina, 34.46; lime, 16-86; magnesia, 5-25; oxide of iron, 0.74.

ANTHOPHYLLITE occurs in crystalline masses with a fibrous columnar structure parallel to the long axes of a rhombic prism, and to both its diagonal. Colour brown and yellowish brown. Streak white. Fracture uneven. Hardness 5 to 5.5. Lustre pearly and inclining to metallic. Translucent to transparent. Specific gravity 3 to 3.5. Found at Kongbog and Modum in Norway, and in the United States, &c. Analysis, by Gmelin: Silica, 56; protoxide of iron, 15; magnesia, 23; protoxide of manganese, 4; lime, 2.5.

ANTHROXITE [ZOLLER, P. C.]

ARGUSITE occurs amorphous. Cleavage parallel to the lateral planes and both the diagonals of a rhombic prism. Colour blue. Fractal uneven. Hardness 3-5. Lustre vitreous. Opal. Specific gravity 3.4 to 3.5. Found in Norway and Greenland. Analysis, by Dr. Thomson: Silica, 96.6; protoxide of iron, 30-164; sesqui-oxide of manganese, 4.9; lime, 15.9; magnesia, 4.56. Anal., by Bottger: Oxyde of oxide of iron, 28.19; oxide of zinc, 45.64; carbocid acid, 16-68; water, 9.98.

AVACHINITE [ZOLLER, P. C.]

BARITE occurs crystallized. Primary form a doubly oblique prism. Colour green or greyish black. Fracture fibrous, with a fibrous structure. Analysis, by Fross: Muriate acid, 16-6; oxide of copper, 76.6; water, 12-8.

BDEREGITE occurs amorphous, sometimes granular, or in massive masses. Colour white, green, or greenish grey, transparent. Hardness low. Found at Lektowsk in the Ural Mountains. Analysis, by Bottger: Oxyde of copper, 28.19; oxide of zinc, 45.64; carbocid acid, 16-68; water, 9.98.

BISMUTHITE [ZOLLER, P. C.]

BAHMATITE occurs crystallized. Primary form a doubly oblique prism. Colour black or greenish black. Fracture uneven. Hardness 5 to 6. Lustre vitreous. Faintly translucent. Specific gravity 3.5. Found at Arendal in Norway, the Shetland Isles, and United States at Charleston, Mass. Analysis, by Arpe, of a specimen from Arendal: Silica, 54.4; protoxide of iron, 12.8; lime, 18-6; magnesia, 2-2; protoxide of manganese, 1.6; alumina, 0.98; volatile matter, 0.9.

BALTICITE is composed of longitudinal fibres adhering to each other. Lustre silky, opaque, but in thin pieces transparent on the cleavage. Colour black, green, or greenish black. Fractal uneven. Hardness 5-6. Lustre vitreous. Faintly translucent. Specific gravity 2.6. Found at Baltimore, U.S.A. Analysis, by Dr. Thomson: Silica, 40:95; magnesia, 34-7; protoxide of iron, 10:05; alumina, 1-50; water, 12-60.

BAROINTOMITE [SHOTTEN, P. C.]

BEZERKITE occurs crystallized in masses confusedly lamellar, or composed of distinct elongated prisms. Cleavage parallel to the axis of the prism. Colour dark steel grey, inclining to brown. Lustre metallic. Found at Chaselles in

Austere, and at Braunsdorf, near Freyberg, Saxony. Analysis, by Berzelius: Antimony, 52.0; sulphur, 30-5; iron, 16; zinc, 0-8.

BERZELITE occurs massive. Colour silver-white. Streak shining. Lustre metallic. Soft, and admits of being smoothed with a small iron ball and polishes a colour of tin. When exposed to the air, undergoes decomposition and becomes black, and frequently occurs of this colour in detritic forms and thin seams. It is found at Smalund in Sweden. Analysis, by Berzelius: Carbonate of tin, 64 = 104.

BERZELITE [LEAD, P. C.]

BERZELITE [MAGHISAN PHARMACOLITE.]

BOLTONITE [FICHEMERITE.]

BORISPOKTOITE [BROKTOITE, P. C.]

BORBORITE occurs crystallized. Primary form a cube. Cleavage parallel to the planes of the octahedron, imperfect. Colour yellowish, greyish or greenish white; streak white. Fracture uneven or imperfectly conchoidal. Hardness 7-0. Lustre vitreous. Transparent, translucent. Specific gravity 2.9 to 3. Found at Segeberg near Kiel in Holstein, Lamberg in Brunswick, and near Turpaca in Peru. Analysis, by Arfwedson: Boricate acid, 69.70; magnesia, 30-30.

BOULOGHRITE (Sulphate of Lead and Antimony) occurs massive. Colour grey. Fracture exhibits a crystalline structure. Lustre metallic. Specific gravity 5.97. Found at Molieres in France and at Nertschinsk. Analysis of the ore from Molieres, by Boulangier: Lead, 53.9; antimony, 25-4; sulphur, 18-4; iron, 2-9; copper, 0-8.

BOURJONITE, compound of the sulphates of lead, antimony, and copper. Colour massive and crystallized. Primary form a right rhombic prism. Cleavage parallel to the primary axes and to both the diagonals of the prism. Colour steel or blackish grey; streak similar. Fracture uneven, conchoidal. Hardness 2-5 to 3-0. Lustre metallic. Opal. Specific gravity 5-79 to 5-83. Found in Cornwall, Cluasthal Pfaffenberg, Mexico, and Peru. Analysis, by Hatchett, of the mineral from Cornwall: Sulphur, 17; lead, 49.28; antimony, 24-28; copper, 12-90; iron, 1-20.

BRAUNITE [MAGNASE, P. C.]

BREitelITe occurs crystallized in delicate capillary crystals of a reddish-brown or chestnut-brown colour, bent and ground like wool. Fibre flexible. Lustre metallic. Found at Veum and Capo di Bove, near Rome, forming woolly coatings in the cavities of the cavities. It contains silica, alumina, and oxide of iron, but in proportions which have not been determined.

BRENNERITE, Bakelite (Carbonate of Magnesia and Iron) occurs crystallized. Faintly translucent, upon an obtuse edge. Colour perfect, parallel to the primary planes. Colour yellow of different shades, and black; streak white. Fracture flat conchoidal. Hardness 4-0 to 4-3. Lustre vitreous, sometimes inclining to pearly. Transparent, translucent. Specific gravity 8-0 to 3-2. Found at Zillertal in Salzburg and other places in the Tyrol. Analysis, by Stromeyer: Carbonate of magnesia, 86-05; carbonate of iron, 15.82; carbonate of manganese, 0-87.

BRENNERITE [ZOLLER, P. C.]

BROCHANTITE (Sulphate of Copper and Water) occurs crystallized. Primary form a right rhombic prism. Cleavage obtained with difficulty, and at the direction of the base of the primary form. Colour emerald-green. Fracture uneven. Hardness 3-5 to 4-0. Lustre vitreous. Translucent, translucent. Specific gravity 3-79 to 3-87. Found in Siberia. Analysis, by M. L. Scopoli: Sulphure acid, 47-17; water, 66-93; oxide of tin, 8-14; oxide of lead, 1-04; water, 11-91.

BROGNIONITE [GLAUCASTERITE, P. C.]

BROGNIONITE occurs in massive aggregations of columnar crystals. Cleavage obtuse to the base of the prism, and both diagonal of a rhombic prism. Colour brown, ash-grey, or dark green; streak lighter. Fracture uneven. Hardness between 4-0 and 4-3. Lustre vitreous. Pseudo-metallic on cleavage planes. Transparent in thin laminae. Mass. Specific gravity 3.3. Found in Upper Styria, the Hartz, in Bayersuth, the Tyrol, the Lizard district of Cornwall,
MIN 304  MIN

Analysis, by Kohler: Silica, 57.19; magnesia, 32.87; lime, 1.29; protocatechuic acid, 7.46.

Brookite. [TITANIUM, P.C.]

Brookite is a black, translucent, opaque mineral. Its crystal structure is monoclinic. The formula is TiO

Cacholong. [OPI, P.C.]

Cadmium, Sulphate of. [CROMBERGERITE]

Cadmium occurs naturally as a by-product of the electrolytic refining of copper. It is extracted from solutions of cadmium sulfate.

Cadmium occurs crystallized. Primary form a rhombohedral prism. Cleavage parallel to the cleavage planes, and the cleavage direction of the prism. Color greenish yellow; streak black; fracture uneven. Hardness 3.5 to 5.0. Luster vitreous to resinous. Transparent, translucent. Found near Taviostock, Devonshire, and at Criniss, Cornwall. Analysis, by Wollaston: 70% of cadmium, 25% of lead, 5% of copper, 4% of zinc, 2% of arsenic, 1% of manganese, 1% of iron, 0.1% of sulphur, and 0.5% of water.

Cobaltite. [ZIEGLER, P.C.]

Cobaltite occurs crystallized. Primary form a rhombohedral prism. Cleavage parallel to the cleavage planes, and the cleavage direction of the prism. Color greenish yellow; streak black; fracture uneven. Hardness 3.5 to 5.0. Luster vitreous to resinous. Transparent, translucent. Found near Taviostock, Devonshire, and at Criniss, Cornwall. Analysis, by Wollaston: 70% of cobalt, 25% of lead, 5% of copper, 4% of zinc, 2% of arsenic, 1% of manganese, 1% of iron, 0.1% of sulphur, and 0.5% of water.

Color: greenish yellow.

Congo Rutile. [TITANIUM, P.C.]

Congo Rutile is a black, opaque mineral. Its crystal structure is monoclinic. The formula is TiO

Copper. [CROMBERGER, P.C.]

Copper is a metallic element with the symbol Cu. It is a ductile, malleable, and corrosion-resistant metal. Copper occurs in nature as native copper and as copper minerals.

Copper occurs crystallized. Primary form a rhombohedral prism. Cleavage parallel to the cleavage planes, and the cleavage direction of the prism. Color greenish yellow; streak black; fracture uneven. Hardness 3.5 to 5.0. Luster vitreous to resinous. Transparent, translucent. Found near Taviostock, Devonshire, and at Criniss, Cornwall. Analysis, by Wollaston: 70% of cobalt, 25% of lead, 5% of copper, 4% of zinc, 2% of arsenic, 1% of manganese, 1% of iron, 0.1% of sulphur, and 0.5% of water.

Cork. [TITANIUM, P.C.]

Cork is a natural, renewable material obtained from the bark of the cork oak tree. Cork is a popular insulating material and is used in a variety of applications.

Criniss. [TITANIUM, P.C.]

Criniss is a town in the county of Cornwall, England, known for its association with the mining of copper and tin. The town has a long history of mineral production.

Crombergerite. [TITANIUM, P.C.]

Crombergerite is a mineral that occurs in the form of crystals, typically in a prismatic habit. It is a black, opaque mineral. The crystal structure is monoclinic. The formula is TiO

Crombergerite occurs crystallized. Primary form a rhombohedral prism. Cleavage parallel to the cleavage planes, and the cleavage direction of the prism. Color greenish yellow; streak black; fracture uneven. Hardness 3.5 to 5.0. Luster vitreous to resinous. Transparent, translucent. Found near Taviostock, Devonshire, and at Criniss, Cornwall. Analysis, by Wollaston: 70% of cobalt, 25% of lead, 5% of copper, 4% of zinc, 2% of arsenic, 1% of manganese, 1% of iron, 0.1% of sulphur, and 0.5% of water.

Crossite. [TITANIUM, P.C.]

Crossite is a mineral that occurs in the form of prismatic crystals. It is a black, opaque mineral. The crystal structure is monoclinic. The formula is TiO

Crossite occurs crystallized. Primary form a rhombohedral prism. Cleavage parallel to the cleavage planes, and the cleavage direction of the prism. Color greenish yellow; streak black; fracture uneven. Hardness 3.5 to 5.0. Luster vitreous to resinous. Transparent, translucent. Found near Taviostock, Devonshire, and at Criniss, Cornwall. Analysis, by Wollaston: 70% of cobalt, 25% of lead, 5% of copper, 4% of zinc, 2% of arsenic, 1% of manganese, 1% of iron, 0.1% of sulphur, and 0.5% of water.

Cyanobium. [TITANIUM, P.C.]

Cyanobium is a mineral that occurs in the form of prismatic crystals. It is a black, opaque mineral. The crystal structure is monoclinic. The formula is TiO

Cyanobium occurs crystallized. Primary form a rhombohedral prism. Cleavage parallel to the cleavage planes, and the cleavage direction of the prism. Color greenish yellow; streak black; fracture uneven. Hardness 3.5 to 5.0. Luster vitreous to resinous. Transparent, translucent. Found near Taviostock, Devonshire, and at Criniss, Cornwall. Analysis, by Wollaston: 70% of cobalt, 25% of lead, 5% of copper, 4% of zinc, 2% of arsenic, 1% of manganese, 1% of iron, 0.1% of sulphur, and 0.5% of water.

Cyanobium occurs crystallized. Primary form a rhombohedral prism. Cleavage parallel to the cleavage planes, and the cleavage direction of the prism. Color greenish yellow; streak black; fracture uneven. Hardness 3.5 to 5.0. Luster vitreous to resinous. Transparent, translucent. Found near Taviostock, Devonshire, and at Criniss, Cornwall. Analysis, by Wollaston: 70% of cobalt, 25% of lead, 5% of copper, 4% of zinc, 2% of arsenic, 1% of manganese, 1% of iron, 0.1% of sulphur, and 0.5% of water.

Fracture conchoidal. Hardness 5 to 5.5. Lustre vitreous.
Transparent, translucent, opaque. Specific gravity 2.4.
Found in a thin limestone quarry near Waldheim in Saxony. Analysis, by Ficinus: Silica, 35.85%;
magnesia, 23.70%; prototioxide of iron, 11.33%;
prototioxide of manganese, 2:50; alumina, 0.416; lime, 0.603; water and carbon dioxide, 20.95.
DIALOGUE. [AGOT, P.C.]
DIAPOROS occurs massive and crystallized. Primary form a doubly oblique prism. Colour slightly greenish grey and yellowish brown. Hardness 6 to 6.5. Slightly translucent. Specific gravity 3.43. Found at Kosoibrod in the Orenburg government of Asiatic Russia. Massive variety occurs in slightly curvilinear laminae of a shining nearly lustre and greenish grey colour; also in cellular masses, constituted of slender crystals, which have a pearly lustre and intercrop each other in every direction; of a brown hue externally, but perfectly transparent and colourless when reduced to thin laminae. Colour index 14; luster, 14.46.
The brown variety, analyzed by Children, gave—alumina, 76.06; water, 14.70; oxide of iron, 7.78; loss, 1.46.
DICHROITE (Iride, Pielmo, Steinbeleite, Cordierite) occurs massive and crystallized. Primary form a rhombohedron, commonly crystallized in six- or twelve-sided prisms. Cleavage parallel to the lateral planes. Colour blue in direction of the axis, and yellowish grey perpendicular to it; sometimes dull yellowish in both directions. streak white. Fracture uneven and somewhat conchoidal. Hardness 7 to 7-8. Lustre vitreous. Transparent, translucent. Specific gravity 2.66. Massive varieties amorphous. Structure inchoate. Fracture conchoidal. Portion of a bed of 100 fathoms in thickness. Analysis, by Gmelin: Silica, 53.16; alumina, 14.03; lime, 14.89; magnesia, 5.2; soda, 2.61; oxide of iron, 7.14; oxide of manganese, 0.64; water, 0.60.
ECCHERNIT (Arzenite of Copper) occurs crystallized. Primary form a rhombic prism. Cleavage indistinct. Colour light greenish grey. Streak white, shining. Hardness 6.5 to 7. Lustre feeble, shining, or dull. Opaline. Specific gravity 3 to 3.1. Found near Eids in the Saxon Eingebolshofen, a bed of 100 fathoms in thickness. Analysis, by Gmelin: Silica, 53.16; alumina, 14.03; lime, 14.89; magnesia, 5.2; soda, 2.61; oxide of iron, 7.14; oxide of manganese, 0.64; water, 0.60.
ECHELORITE occurs massive without any trace of cleavage. Colour brownish black. In thin splinters has a reddish brown transluclency, lighter than the streak. Streak reddish brown. Fracture subconchoidal. Hardness, scratches thorite. Lustre metallic, grey to black; streak white. Fracture uneven. Analysed, in Norway. Analysis, by Scherer: Columbic acid, with some tinic acid, 46-98; tinic acid, 7.94; yttria, 26-69; prototioxide of uranium, 0.14; prototioxide of cerium, 2.18; oxide of lanthanum, 0.65; lime, 2.47; magnesia, 0.28; water, 3.97=98.90.
ECHELORITE. [FAYRIZHE, P.]
ECHELORITE occurs crystallized in the form of a thin octahedron with a square base. Colour white, sometimes brown. Fracture vitreous or uneven. Frangible. Lustre brilliant. Found at Kaisarmuths in Breisgau. Analysis, by Damour: Silica, 49.36; alumina, 10.77; lime, 5.00; soda, 3.04; water, 23.49.
FIBROLITE. [KAINITIS, P.C.]
FIBROLITE. [KAINITIS, P.C.]

FIBROLITE. [KAINITIS, P.C.]
FIBROLITE. [KAINITIS, P.C.]
FIBROLITE. [KAINITIS, P.C.]
granular and conoidal. Colour lead grey. Streak the same. Hardness between mica and calcareous spar. Lustrous metallic.

Oplutens: 4-5. Found in the silver-mine at Alhambra, Mexico. Analysis, by Herrera: carbonic acid, 31-86; peroxide of anhydrous, 12-22; tellurium, 55-58. This mineral is probably a mixture rather than a definite compound.

Heraldine: [Maflente, Ores of, P. C.]

Herlandite: [Zeolites, P. C.]

Hisingerite: [Thraustite, P. C.]

Honey-stone: [Melrite, P. C.]

Horn-stone: [Dumrite, P. C.]

Horn-stone, Fusible: [Fusite, P. C.]

Hornstone, Infusible: [Quartz, P. C.]

Humboldtite: [Sorrelite, P. C.]

Hydronoracite occurs in small needle crystals, which appear to be flat six-sided prism. Colour white, with spots of red from silicified peroxide of iron. Hardness similar to that of pyrophyllite. Specific gravity 2-04. Found in a collection of Caucasian minerals. Analysis, by Hess: Boracic acid, 49-22; lime, 13-74; magnesia, 10-71; water, 26-83.

Hydrohalite occurs massive, investing steatite in foliated masses. Colour white. Streak the same, with a pearly lustre. Translucent, with a soaply feel. Hardness 2. Found at Sarum. Analysis: Magnesia, 30-30; alumina, 12-90; peroxide of iron, 6-50; carbonic acid, 10-54; water, 32-06; insoluble residue, 1-20.

Hydromagnesite: [Magnesite.]

Hydrochlorite: [Greek Iron Earth.]

Hydrochrome: [Greek Iron Earth.]

Hydrocystite: [Hydromagnesite, Ores of, P. C.]

Iron: [Titanous, Ores of, P. C.]

Jasper: [Quartz, P. C.]

Johannisite: [Uralium, Ores of, P. C.]

Johnstonite: [Lead, Ores of, P. C.]

Kammererite: occurs crystallized and massive. Common form of the crystal a six-sided prism. Cleavage perpendicular to the axis only. Cleavage places have a pearly lustre. Colour, that of some crystals, which by daylight is dark that their red colour is scarcely perceptible, appears by candlelight quite red. Rarely, usually composed of fine laminae. Colours sometimes dark violet blue, sometimes yellowish or greenish, or greenish white. Translucent on the edges, particularly after immersion in water. Fracture compact, sub- or non-glistening sublustrary. Irregular variety, usually composed of fine laminae. Found in the Ural mountains. Analysis, by Hartwell: Silica, 37-0; alumina, 14-2; magnesia, 31-5; lime, 1-5; oxide of chromium, 1-0; water, 13-0.

Kerkinite occurs massive and reniform. Structure lamellar or compact. Colour white, yellow, or green. Streak white. Fracture conchoidal. Hardness 2-0 to 2-5. Lustre vitreous or resinos. Transparent, translucent. Specific gravity 2-040. Found in the Ural mountains. Analysis, by Hartwell: Silica, 37-0; alumina, 14-2; magnesia, 31-5; lime, 1-5; oxide of chromium, 1-0; water, 13-0.

Kersite: [Magnetite, Ores of, P. C.]

Kersite resembles sulphur of antimony, but is more

**Kollertite (Hydrous Silicate of Alumina)** occurs massive. Colour white. Fracture earthy. Nearly opaque. Lustre submetallic. Specific gravity 3-5. Found at Schenken in Hungary, and in a load-mine on the bank of the river Oo in the Pyprenees. Analysis, by Berthier: Silica, 19; alumina, 44.5; water, 44.5; oxide of iron, 1-45; oxide of copper, 1-08; ginger, 1-49 to 99.4.

**Lecithnite (Hydrous Silicate of Alumina)** occurs massive. Colour white. Fracture earthy. Nearly opaque. Lustre submetallic. Specific gravity 3-5. Found near Wolschthain in Russia. Analysis, by Berthier: Silica, 19; alumina, 44.5; water, 44.5; oxide of iron, 1-45; oxide of copper, 1-08; ginger, 1-49 to 99.4.

**Lecithnite (Phosphate of Copper)** occurs in small octahedral crystals and in massed masses. Primary form a right rhombic prism. Colour dark green. Streak green. Fracture uneven. Hardness 4-0. Translucent. Lustre resinous. Specific gravity 3-6. Found at Libethen in Hungary. Analysis, by Berthier: Phosphoric acid, 20.7; oxide of copper, 63.9; water, 7-4.

**Ligurite.** Primary form an obtuse rhombic prism. Colour olive green. Streak greenish grey. Fracture uneven. Hardness about 2-0. Transparent. Lustre resinous. Specific gravity 3-0. Found on the banks of the Stura in the Apennines of Liguria. Analysis, by Viviani: Silica, 57-45; alumina, 7-36; carbonates of lime and magnesia, 25-90; oxide of iron, 1-56; oxide of manganese, 0.58 to 0.16.

**Lime.** Occurs crystallized. Primary form an obtuse rhombic prism, and from one to one-fourth of an inch long. Colour fresh yellow. Fracture conchoidal. Hardness rather less than calcars. Very brittle. Lustre similar to that of sulphur of lead. Transparent. Fracture. Specific gravity 1-833. Supposed to have come from Hungary. Analysis, by Sandell: Oxygen composition to be oxalate of lime with one equivalent of water.

**Magnesia Alem occurs massive. Structure fibrous, also compact. Colour white. Streak white. Colour white. Streak white. Found at Cape Verde, in Southern Africa, where it covers the floor of a grotto to the depth of six inches. Analysis, by Stromeyer: Sulphate of alumina, 38-996; sulphate of magnesia, 10-990; oxide of manganese, 4-97; chloride of potassium, 0.205; water, 45-739.

**Magnesia, Hydrate of.** [Shepardites.]

**Magnesite (Carbonate of Magnesia)** occurs in acicular crystals, massive, and in powder. Colour usually white, occ-
casionally greyish and yellowish. The massive varieties are found amorphous, reniform, nodular, and stalactitic. Fracture splintery or flat conchoidal. Hardness exceeds that of calcite.

Specified gravity 2.8. Known in several parts of Europe, as Styria, Moravia, Spain, and Silesia, in India, and at Hoboken in New Jersey, North America. Analysis, by Rammelsberg: Carbonic acid, 52.21; mica, 19.77; water, 24.02.

Malachite occurs in these plates and massive. Fracture uneven or conchoidal. Colour white or yellowish. Streak shining. Soft like wax. Lustre waxy, weak. Streak transparent. Specific gravity 1.6 to 1.8. Known at St. Dorffal between Lohau and Bazzen, and near Bora in Bohemia. Analysis, by Melasmer: Silica, 50.2; alumina, 10.7; lime, 0.2; peroxide of iron, 31; water, 35.6.

Margarite (Pearl Mica) occurs in thin hexagonal crystals, and in masses of small thin shining laminae. Primary form a rhombohedron. Cleavage distinct parallel to the bases, and distinct parallel with the sides. Colour greyish, reddish, and yellowish white. Streak white. Fracture not observable. Hardness 3.5 to 4.5. Rather brittle. Lustre pearly on the terminal faces, vitreous on the others. Translucent. Specific gravity 3.5 to 4.1. Found at Sterling in the Tyrol. No accurate analysis appears to have been made.

Marcelite (Anhydrous Sili cate of Detonix of Magnesia) occurs crystalline in octahedrons with a square base. Colour greyish black. Lustre slightly metallic or vitreous. Forms perfect crystalline, 12 faces. Analysis, by Bernasch: Silica, 15.17; oxide of magnesia, 75.90; oxide of iron, 4.14; alumina, 2.86. The analysis by Berthier gives considerably more silica and less oxide of magnesia.

Marcasite, Ore of Iron (Marcasite, Marcassite, Marcasite Iron Ore) occurs massive. Structure columnar, irregularly intersecting. Columnar portions foliated, having a cleavage in two directions intersecting each other at nearly right angles and giving a pearly and lustrous. Translucent, opaque. Specific gravity 4.27. Found at Hoboken, New Jersey, and the Bare Hills, near Baltimore, United States. Analysis, by Nuttall: Silica, 56; magnesia, 46.8; lime, 1.9; water, 40.1.

Mardagn (Sulfate of Ammonia) occurs stelactitic, pustuliferous, or efflorescent. Colour yellow or greyish. Taste acid, bitter. Translucent, opaque. Found in the fissures of the earth, and among the laves of Etna and Vesuvius, in the Sofia, and near Sienna in Tuscany. Analysis, by Gmelin: Sulfuric acid, 58.98; ammonia, 22.80; water, 23.91.

Mineral [Arsenical Minerals, P. C.] Mica. It is remarked by Brooke that several distinct appearances are included under this name, merely because they may be easily split into very thin shining plates; but they cannot at present be distinguished by any characters which have been hitherto given. He treats of the various substances belonging to this mineral, under the heads of Rhombooidal Mica; Oblique Prismatic Mica; Lepidolite, or Linne Mica [P. C.]; Margarite, Pearl Mica; Rubelians, or Red Mica; Oderit, or Black Mica [P. C.].

Rhombooidal Mica occurs in thin crystals and massive prisms. Primary form a rhombohedron. Cleavage very distinct, perpendicular to the axis. Fracture not observable. Hardness of the cleavage surfaces 2.0 to 2.5, that of the edges 3.5 to 5.5. Colour, usually grey, black, brown, pale red, brownish green. Streak white, grey. Lustre vitreous, nearly on the cleavage surfaces. Transparent, translucent. Massive varieties globular, structure fibrous, foliated. Amorphous, structure foliated, granular, fibrous, or crystalline. Oblique Prismatic Mica. Primary form an oblique rhombic prism, and according to Brooke the preceding descriptions will probably apply to this variety, except as to the form. Frank, by Rose: Silica, 47.19; alumina, 33.98; peroxide of iron, 4.47; oxide of manganese, 2.54; lime, 0.13; fluorite Acid, 0.39; potash, 8.8; water, 4.07 = 100.88.

Marmatite occurs in rounded masses, seldom larger than a pea, or in layers a sixteenth of an inch or less in thickness, between layers of coal. Colour reddish brown by reflected light, and deep red by transmitted. Powder light brown. Translucent in small fragments. Hard and brittle. Lustre resinous. No taste or smell. Blackness on exposure. Specific gravity 1.6. Found about the middle of the main coal or Haigh Moor seams at the Middleton colliers near Leeds; also at Newcastle. Analysis, by Johnston: Carbon, 46.83; hydrogen, 4.47; oxide of iron, 4.27; peroxide of iron, 3.90; oxide of manganese, 1.82; lime, 0.13; fluorite Acid, 0.39; potash, 8.8; water, 4.07 = 100.88.

Mornadrite occurs massive. Cleavage, one distinct, and another imperfect. Colour pale yellowish, verging on red. Hardness nearly that of felspar. Lustre vitreous. Specific gravity 2.63. Found at Jorgs, P. C. Analysis, by Erdmann: Silica, 56.07; magnesia, 31.63; protopside of iron, 8.56; water, 4.04.

Monticellite occurs crystallized. Primary form a right rhombic prism, rarely with a perfect prism, and having a usual axis of quartz. Colour generally yellowish. No cleavage planes have been observed. Hardness 5.0 to 6.0. Sometimes nearly transparent and colourless. Found at Vesuvius. It has not been seen in Britain.

Morandrite occurs massive and fibrous, and crystallized in flat prisms. Cleavage in one direction distinct, in others indistinct. Colour dull reddish-brown. Streak greyish brown. Hardness 3.0. Lustre of cleavage face between vitreous and greasy; of other surfaces resinous. Thin splinters translucent and showing a bright red colour by transmitted light. Specific gravity 2.98 to 2.98. Found at Lammanpokket in Sweden. Analysis according to Erdmann it consists mostly of silica, titanic acid, and the oxides of cerium and lanthanium, with some oxide of manganese, lime, a little magnesia, potash, and water.

Nexite. Oek occurs crystallized in acicular four- or six-sided prisms, indistinctly terminated and longitudinally striated. Cleavage parallel to the axis of the prism. Colour, when first broken, steel-grey or black lead-grey, soon acquiring a yellowish or ochreous tint. Cross fracture often conchoidal with a shining metallic lustre. Hardness 2.0 to 2.5. Opaque. Specific gravity 6.125. Found near Ekaterinburg in Siberia. Analysis, by Friek: Sulphur, 11.58; bismuth, 43.20; copper, 12.10; nickel, 1.58; tellurium, 1.32.

Nuziterite. Occurs in crystals, which are almost lenticular. Primary form a rhombohedron. It is generally found implanted in marmatite and allied to cleavelandite. Colour yellowish white, greyish. Fracture somewhat conchoidal. Hardness 4.0. Lustre greasy, feeble. Specific gravity 6.0415. Found in the mine of Nusselare, near Beauraing, dep. of Luxembourg. Analysis, by Bernasch: Phosphate of lead, 56.4; phosphate of lime, 22.20; chloride of lead, 7.66; arsenate of iron, 6.50.

Greentieite occurs crystallized. Primary form a right square prism, and prolonged parallel to the four edges. Hardness 6.5. Specific gravity 3.628. Found at Arendal, Norway. Analysis: Titanate of zirconia, 68.985; silica, 19.700; lime, 2.612; magnesia, 2.047; protopside of iron, 1.1936; water, 5.352.

OXOCLOSCE occurs crystallized. Primary form an oblique rhombic prism. Colour white, yellowish, and greenish white. For description, see previous. Analyses, by Bernalis: Silica, 56-99; lime, 26-35; water, 16-65. Specific gravity 3.2-4. Translucent. Specific gravity 2.6-4 to 2.97. Found at Davnitzske near Stockholm, Arden in Norway, &c. Analysis, by Bernalis: Silica, 63-70; alumina, 29-95; lime, 9-05; soda, 6-45; potash, 1-20; oxide of iron, 0-50.

ORTORLITE occurs in small rounded brilliant plates, with a perfect basal cleavage. Colour greyish or greenish. Streak pale green. Fracture uneven. Scratches with difficulty. Specific gravity 3.5. Found near Otrers on the borders of Luxembourg. Analysis, by Damou: Silica, 43-34; alumina, 24-83; protolite of iron, 16-72; protolite of manganese, 8-0; water, 8-0.

ORZELICHE (Carbonate of Hydrogen). Colour yellowish brown. Translucent; has a slight bituminous odour, and softens by the heat of the hand, so that it may be knotted. Fusible readily, emitting a stronger bituminous odour; burns with a clear bright flame without residue. Insoluble in water, only slightly in alcohol, but readily in ether and oil of turpentine. Found in considerable masses at Shink in the Buchan district of Scotland, and used for fuel. Analyses, by Carbon, 69-204; hydrogen, 3-876. It appears to be similar in composition to Hatchetine.

PARAGNITE. (Augite, P. C.) PRAEVENTITE, occurring on spherical masses which have a radiating fibrous structure. Colour greyish. Hardness 4-0 to 5-0. Lustre nearly opaque. Specific gravity 3.69. Found in large masses on Monte Bracho, in the Southern Tyrol. Analyses, by Von Kobell: Silica, 51-30; lime, 38-77; soda, 8-96; potash, 1-57; alumina and oxide of iron, 0-90; water, 3-89.

PHARMACOLITE, MAGNESIAN. [MAGNESIAN PHARMACOLITE]

PHARMACOSIDERITE occurs crystallized. Primary form a rhomboid. Cleavage parallel to the primary faces. Colourless; also bright yellow, yellow, inclining to red. Hardness above 5-0. Lustre vitreous. Transparent to opaque. Specific gravity 3.169. Found near Freiburg, Germany. Analysis, by Hartwell: Silica, 55-14; glucine, 44-47; alumina and magnesia, 0-39.

POLYCARITE, a hydrous silicate of alumina, probably similar to HALITEES. PHOSPHOREIT [Apatite, P. C.]

PHYLITE. [GIGANTOLITE]

PIEKAROWSKITE (Magnesia Alum) occurs in masses composed of long parallel fibres of a silky or satin lustre. Colour white, or, viewed in the direction of the fibres, pale rose-red or light green. Compact, but easily divided parallel with the fibres. Brittle. Specific gravity 1-78 to 1-80. Found at Taranipa in Peru. Analysis, by Strecker: Sulphate acid, 36-770; alumina, 11-515; magnesia, 3-690; peroxide of iron, 2-617; chlorid of potassium, 0-205; water, 45-739.

PLACOITE. [Turrite, P. C.]

PLATINE. [Nickel, Ore of P. C.]

POLISHING SLATE (Polier schiefere) occurs massive, with a flat texture. Colour white, yellowish white, or yellow. Brittle. Opague. Specific gravity 0-59. Found near Bilin in Bohemia, at Zwieka in Saxony, and Auvergne, and is supposed to be a volcanic product. Analyses, by Bucholz: Silica, 83-50; alumina, 4-00; lime, 8-90; oxide of iron, 1-50 water, 9-00.

POWERSITE. [Talc, P. C.]

PRASE. [Quartz, P. C.]

PRASEOLITE occurs imperfectly crystallized in prisms of several sides, with the edges rounded. Cleavage in one direction. Colour olive green; streak clear green. Fracture splintery and flat conchoidal. Hardness 3-5. Lustre weak. Specific gravity 2-754. Found near Breivig, Norway. Analyses, by Erdmann: Silica, 40-94; alumina, 28-79; prot-
oxide of iron, 4;06; potassium of manganese, 0;82; magnesia, 13;73; tannic acid, 0;40; oxide of lead, copper, and cobalt with lime, 0;50; water, 7;38.

P. Prasolite occurs massive. Composed of loosely adhering flakes. When dry, it is grey-green and not perfectly clear; on scraping, it is a dirty red-brown and may be crumbled to powder between the fingers. Specific gravity 2;311. Found on the Killpatrick Hills. Analysis, by Dr. Thomson: Silica, 38;55; magnesia, 15;55; peroxide of iron, 14;99; alumina, 6;65; lime, 2;96; oxide of manganese, 1;50; water, 18;00. The loss amounting to 3 per cent. is attributed to an alkali.

Prasolite [MARGANZEE, Ores of P. C.] Found at (Bouquet, N. Y.). Occurs crystallized and massive. Primary form a cube, the faces of which are usually curvilinear. Cleavage parallel to the faces of the regular octahedron, indistinct. Fracture uneven, conchoidal. Hardness 3. Colour purple-brown and reddish brown; tarnishes speedily after being cut. Streak greyish black. Luster metallic. Specific gravity 5;0. Massive variety amorphous, structure compact. Found in Cornwall and most copper mines. Analysis, by R. Phillips: 4 sp. from Bove Island, Lake of Killarney, Ireland: Sulphur, 23;75; copper, 61;07; iron, 14;00; silica, 0;50.

P. Fyrop [GABETS, P. C.] Found in Cornwall. Primary forms a rhombic prism, with one perfect cleavage, and another at right angles to this, imperfect. Colour emerald-green and apple-green; streak white. Fracture uneven and splintery. Hardness 3;0. Luster dull. Translucent. Specific gravity 2;974. Found in the island of Elba, and at Aker in Siderand. Analysis, by Von Kobell: Silica, 37;03; alumina, 18;60; magnesia, 31;62; peroxide of iron, 2;62; oxide of chromium, 1;48; water, 1;00.

PYRRHITE occurs crystallized in regular octahedrons. No cleavage observable. Colour deep orange-yellow. Hardness equal to that of felspar. Luster vitreous, brilliant. Transparent on edges. Found at Alaksesscha, near Murmansk, and at the Azores. It has not been analyzed.

RUSHIT (Soda Sulphate of Magnesia) occurs in flat six-sided prisms, acicular crystals, and needle-like efflorescences. Colour green. Fracture conchoidal to birefringent. Found in the vicinity of Seili and of Socolechus in Bohemia. Analysis, by Reuss: Sulphate of soda, sulphate of magnesia, 31;65; murate of magnesia, 2;19; sulphate of lime, 0;42.

Riolite [ZINC, Ores of P. C.] ROOMER occurs crystallized in square octahedrons, in greenish or yellowish, translucent, Colour blue-green, or honey-yellow. Hardness scratchless. Found at St. Marcel in Piedmont. Analysis, by DANCE: Antimonious acid, 79;17; lime, 16;65; peroxide of manganese, 2;16; peroxide of iron, 1;19; silica, 0;64.

R Priest occurs in small grains, without crystallization. Fracture splintery, and in the larger grains somewhat foliated. Surface of the fracture shining. Colour fain rose-red to brownish red; the former more common. Subtranslucent. Hardness 2;5. Specific gravity 2;72. Found in Siderand. Analysis, by Svenberg: Silica, 44;901; alumina, 31;506; peroxide of iron, 2;688; oxide of manganese, 0;191; potash, 0;028; lime, 3;592; magnesia, 2;499; soda, a trace; water, 6;333.

RUBELLAN (Red Mica?) occurs in small hexagonal plates, mica-like and optical. Colour greenish-brown. Hardness 2 to 2;5. Luster pearly. Transparent, opaque. Specific gravity 2;8 to 3;1. Found at Schams in the Mittelgebir ge, Bohemia. Analysis, by Klaproth: Silica, 45; alumina, 10; oxide of iron, 2;9; oxide of manganese, 0;15; of volatile matter, 5;4.

Rutile [TITANIUM, Ores of P. C.] SAULITE [PYROXENE, P. C.] SAPHIRINE occurs granular disseminated in anthophyllite. Colour olive-brown; streak greenish-brown. Fracture un- even, conchoidal. Hardness 7 to 8;0. Luster vitreous. Translucent. Specific gravity 3;42. Found at Akulke in Greenland. Analysis, by Stromeyer: Silica, 14;50; alumina, 7;11; magnesia, 16;85; lime, 0;28; oxide of iron, 3;92; oxide of manganese, 0;58; water, 0;49.

P. Fyrop [GABETS, P. C.] Found in Cornwall. Primary forms a rhombic prism, with one perfect cleavage, and another at right angles to this, imperfect. Colour emerald-green and apple-green; streak white. Fracture uneven and splintery. Hardness 3;0. Luster dull. Translucent. Specific gravity 2;974. Found in the island of Elba, and at Aker in Siderand. Analysis, by Von Kobell: Silica, 37;03; alumina, 18;60; magnesia, 31;62; peroxide of iron, 2;62; oxide of chromium, 1;48; water, 1;00.

PYRRHITE occurs crystallized in regular octahedrons. No cleavage observable. Colour deep orange-yellow. Hardness equal to that of felspar. Luster vitreous, brilliant. Transparent on edges. Found at Alaksesscha, near Murmansk, and at the Azores. It has not been analyzed.

RUSHT (Soda Sulphate of Magnesia) occurs in flat six-sided prisms, acicular crystals, and needle-like efflorescences. Colour green. Fracture conchoidal to birefringent. Found in the vicinity of Seili and of Socolechus in Bohemia. Analysis, by Reuss: Sulphate of soda, sulphate of magnesia, 31;65; murate of magnesia, 2;19; sulphate of lime, 0;42.

RIOLITE [ZINC, Ores of P. C.] ROOMER occurs crystallized in square octahedrons, in greenish or yellowish, translucent, Colour blue-green, or honey-yellow. Hardness scratchless. Found at St. Marcel in Piedmont. Analysis, by DANCE: Antimonious acid, 79;17; lime, 16;65; peroxide of manganese, 2;16; peroxide of iron, 1;19; silica, 0;64.

ROSETE occurs in small grains, without crystallization. Fracture splintery, and in the larger grains somewhat foliated. Surface of the fracture shining. Colour fain rose-red to brownish red; the former more common. Subtranslucent. Hardness 2;5. Specific gravity 2;72. Found in Siderand. Analysis, by Svenberg: Silica, 44;901; alumina, 31;506; peroxide of iron, 2;688; oxide of manganese, 0;191; potash, 0;028; lime, 3;592; magnesia, 2;499; soda, a trace; water, 6;333.

RUBELLAN (Red Mica?) occurs in small hexagonal plates, mica-like and optical. Colour greenish-brown. Hardness 2 to 2;5. Luster pearly. Transparent, opaque. Specific gravity 2;8 to 3;1. Found at Schams in the Mittelgebirge, Bohemia. Analysis, by Klaproth: Silica, 45; alumina, 10; oxide of iron, 2;9; oxide of manganese, 0;15; of volatile matter, 5;4.

Rutile [TITANIUM, Ores of P. C.] Saulite [PYROXENE, P. C.] Saphirine occurs granular disseminated in anthophyllite. Colour olive-brown; streak greenish-brown. Fracture uneven, conchoidal. Hardness 7 to 8;0. Luster vitreous. Translucent. Specific gravity 3;42. Found at Akulke in Greenland. Analysis, by Stromeyer: Silica, 14;50; alumina, 7;11; magnesia, 16;85; lime, 0;28; oxide of iron, 3;92; oxide of manganese, 0;58; water, 0;49.
Specific gravity 6.2 to 6.4. Found at Lead-hills, in Scotland. Analysis, by Brooke: Carbonate of lead, 72.5; sulphate of lead, 27.5.

**STANNITE** (Barystannomolybdate). [SYNTHETIC, P. C.]

**TELLURIAN SPAR.** [WOLLASTONITE, P. C.]

**TELLURIBORITE** (Tellure of Bismuth). [TETRACUIUM, Ores of, P. C.]

**TETRAPHYLLITE** occurs crystalized and massive. Primary form a right rhombic prism. Massive variety has a closely lamellar or crystalline structure, with cleavages parallel to the planes of a right rhombic prism. Colour greenish grey. streak greyish white. Hardness 5-5. Translucent in thin pieces. Specific gravity 3.6. Found at Bodenmais in Bayern. Analysis: Phosphoric acid, 41.47; protopside of iron, 48.57; protopside of manganese, 4.70; lithia, 3.40; silica, 0.53; Anal.

**UMBASAITE** (Columbite Garnet) occurs crystalized in rhombohedral crystals. Colour emerald green. Hardness 7-7. Fracture transgranular. Specific gravity 3.81. Found at Beaserek, in the Urals mountains. Analysis, by Kornesien: Silica, 37.11; alumina, 5.88; oxide of chromiun, 29.94; protopside of iron 2.44; lime, 30.44; magnesia, 6.10; water, 0.91.

**VAUQUELINEITE**. [CHROMIUM, Ores of, P. C.]

**VILLASITE**. Primary form a rhombohed prism. Colour yellowish green. Fracture granular. Hardness 3-3 to 3.5. Brittle. Translucent to transparent. Specific gravity 3.11. Found in Spanish Cusco, Peru. Analysis, by Dufresnay: Silica, 36.61; magnesia, 43.37; protopside of iron, 3.39; protopside of manganese, 2.42; lime, 0.58; potash, 0.58; water, 5.30.

**VOLBOVOLITE** (Vanadinite of Copper) occurs in small clusters of olive-coloured crystals, sometimes united into globular masses. Streak green, almost yellow. In thin splinters, transparent, with a vitreous lustre. Hardness, scratches calcareous. Specific gravity 4.05. Found on examining some Siberian copper-ores. Von Volbort, who examined it, has not given an exact analysis.

**WOLFAITE** (Iron Alum) occurs crystalized in regular octahedrons. Colour bronze black. Found at the Solfatara near Naples. Analysis, by Dufresnay: Sulphuric acid, 45.67; protopside of iron, 28.69; alumina, 3.27; potash, 5.47; water, 17.30.

**WAGNERITE** (Fluoride of Titanium and Iron). Primary form an oblique rhombic prism. Fracture uneven. Colour yellow, or different shades; often greyish. Streak white. Hardness 5 to 5.5. Lustre vitreous. Translucent. Specific gravity 3.11. Found in the valley of Holgabren in Salzburg. Analysis, by Fuchs: Phosphoric acid, 41.73; hydrofluoric acid, 6.50; magnesia, 48.66; oxide of iron, 5.00; oxide of manganese, 0.5.

**WAGNERITE** (Fluoride of Titanium and Iron). Primary form an oblique rhombic prism. Cleavage parallel to the longer diagonal, perfect. Colour dark brown brown to iron grey, and often with a copper-red tinge on the face of perfect cleavage. Decomposing crystals are nearly iron black, with a faint tinge of purple. Fracture uneven. Hardness 5.5 to 6.0. Brittle. Lustre metallic-pearly on the cleavage surface; of other surfaces, vitreous or subvitreous, often nearly dull. Specific gravity 3.3 to 3.32. Found near Amity and Enderville, in the State of New York. Analysis, by Shipheard: Titanium, 64.71; iron, 2.14; yttrium, 0.80; fluorine, 27.33.

**WASHINGTOITE** (Lithianite). [TITANIUM, Ores of, P. C.]

**WILLMERITE** occurs in oblique rhombic prisms. Colour ash-grey or brownish. Presents only feeble traces of cleavage. Fracture even or coarse granular. Hardness, scratches glassy, by the unaided eye. Translucent to transparent. Specific gravity 2.60. Found at Fabien, Sweden. Analysis, by Wachtmeister: Silica, 58.69; alumina, 21.70; magnesia, 8.99; protopside of iron, 1.43; protopside of manganese, 0.63; potash, 4.10; soda, 0.68; oxide of zinc, 0.3; water, with a little ammonia, 3.20.

**WILLEMITE** [SCOFIELDITE, P. C.]

**WILLEMITE** occurs in angular grains, and in tabular crystals; form indeterminate. Cleavage distinct in one direction. Colour light yellow, wine-yellow, honey-yellow, brownish yellow. Streak yellowish white. Fracture more or less conchoidal, splintery. Hardness 2-2. Lustre vitreous. Subtranslucent. Transparent. Specific gravity 3.41. Found in an island near Brevig in Norway. Analysis, by Schercher: Silica, 30.62; columbic acid, 14.47; zirconia, 15.17; iron, 19.12; soda, 7.78; oxide of iron, 3.12; protopside of manganese, 1.55; magnesia, 0.40; water, 0.54.

**WORTHITE** occurs in rolled masses, having a foliated crastalline structure, and sometimes presenting very small apparently detached prisms. Colour white. Lustrous, metallic. Hardness 2-2. Lustre vitreous. Translucent. Specific gravity 3.1. Found near St. Petersburg, and on the shores of the Bay of Finland. Analysis, by Dr. Heuss: Silica, 40.79; alumina, 53.06; magnesia, 0.58; water, 4.68.

**YELLOW COPPER-ORIE (Copper Pyrites) occurs crystalized and massive. Fracture forms a square prism. Common form a tetrahedron. Fracture conchoidal. Colour brown yellow, frequently with a violet and purple tints on the surface. Streak greenish black. Lustre metallic. Hardness 2-4 to 4.5. Specific gravity 3.57. Found in Cornwall, and in most copper- mines. Analysis, by Rose: Copper, 33.12; iron, 30; sulphur, 36.59.

**YTBRODITE**. [YTTRIUM, P. C.]

**YTTRVANTHALITE**. [YTTRIUM, P. C.]

**ZAAGANITE** [PHILLIPSITE, P. C.]

**ZENITE.** [EPIDOTE, P. C.]

**MINES.** Mines are properly openings in the ground from which any thing is dug. Until an opening is made, the name is not properly applied, though the term is now generally used to signify coal, lead, iron and so forth, before an opening is made for digging out.

Mines belong to the tenant in fee-simple of the land, with the exception of gold and silver mines, which belong to the king by his prerogative, but by 1 W. & M. c. 80, a mine of copper or tin is not to be considered a royal mine, though silver be extracted from the ore. The owner of land in fee-simple is the owner of everything which lies in a perpendicu- lar direction under the surface to any depth. A tenant for life, unless his estate is without impeachment of waste, cannot dig earth, lime, clay or stone, except for the repair of buildings or the manuring of the land. In fact the general principle is that the land, which term comprehends everything in its or that is permanently attached to it, cannot be taken away by any other person than the tenant in fee- simple or a tenant in tail. Accordingly a tenant for life cannot open a new mine, but he may work mines which are already open, and he may open new shafts for working veins of coals which have been already worked. A tenant in tail has an estate of inheritance, and incident to it the power of commit- ting waste, as by cutting down timber or opening mines.

If a man who has a right to a mineral in fee-simple, open the mines upon it, the lessee is thereby empowered to dig for the minerals; and if he leases lands on which mines are already open, the leasees may work them.

The freehold interest of lands is vested in the lord, and it is a legal consequence that he has the freehold of the mines. In some cases a copyholder of inheritance has by the
custom of the manner a right to the timber, and the lord has no right to dig mines, unless there be a custom which gives him the right.

A partnership for working a mine is subject to the same legal rules as any other partnership. [PARTNERSHIP, P. C.]

MITCHELL, THOMAS, was born on the 30th of May, 1783, in London, and was the son of a riding-master. At the age of seven he was admitted into Christ's Hospital, where he remained until the year 1802, when he went to Pembroke College, Cambridge, on one of the exhibitions of the College. In 1806 he took his degree of B.A., and the distinguished manner in which he acquitted himself at college induced the governors of Christ's Hospital to present him with a handsome silver cup. He did not however obtain a fellowship, as he had hoped, for no more than two persons educated at the same school are allowed to hold fellowships in Pembroke College at the same time. This regulation, which was then made and carried into effect for the first time, deranged all Mitchell's schemes, who had determined to devote himself to philologous pursuits. A few years afterwards however he obtained a scholarship as a fellow of Pembroke College, Cambridge. Mitchell never married, and if he had taken holy orders he might have remained in the enjoyment of that fellowship for life, and would have added many more volumes to the Eddystone stone, after which he was afterwards exposed. But he never took orders from a fear of the great responsibilities of the pastoral office, and consequently, after a limited number of years, he was obliged by the statutes of the college to vacate his fellowship. He afterwards earned his livelihood by private tuition and by writing for the press; he was engaged for ten years as tutor in private families. In 1818 he commenced a series of essays for the Quarterly Review on Aristotle, and on Athenian manners, and this led him to translate some of the plays of Aristophanes into English verse; his translation appeared in 2 vols. 8vo., 1820-22. His articles in the 'Quarterly Review' impressed the patrons of a vacant Greek chair in one of the Scotch universities with so much respect for his classical attainments, that they invited him to accept the situation; but as he would have had to sign the Confession of the Scotch Kirk, which was to him an insurmountable obstacle, he declined the lucrative office, notwithstanding his poverty. During the last twenty years of his life Mitchell lived with some of his relations in the county of Oxford, and occasionally superintended the publication of some portion of the Greek works which he himself had time printed at the Clarendon press. During the years 1834-38 he edited, in separate volumes, five of the plays of Aristophanes, with English notes; and in 1839 he began an edition of Sophocles, likewise with English notes; but after the first three tragedies had appeared, the publication was suspended in 1842, because English notes were thought objectionable; and Mitchell now had no other employment but what the Clarendon press might casually offer. The almost entire cessation of literary income not only caused him great pecuniary difficulties, but broke down his health and spirits. His friends became alarmed about him, and made his condition known to Sir Robert Peel, who immediately placed at his disposal the sum of 150l. from the royal bounty fund. In 1848 the publication of Sophocles was resumed, and the remaining five of the Greek plays were like so many editions with briefer notes than the preceding three. In 1844 he undertook the publication of a minor edition of a 'Pentalogia Aristophanica,' with short Latin notes, and had nearly completed his task when he died suddenly, on the 5th of March, 1846, at his house at Steeple Aston near Woodstock. His health had long been in a weak state, but his death was unexpected.

The works which Mitchell edited and commented upon contain evidence that he was a Greek scholar of considerable eminence; but his notes are often irrelevant, and the text of his author is seized upon to furnish opportunities of showing his critical opinions and a passionate attachment to the Athenian democracy and democratic forms of government in general. [CLASSICAL MUSEUM, vol. iii, p. 213, 3rd.]

MITE. [ARABS, P. C.]

MITFORD, WILLIAM, the eldest son of John Mitford, Esq., of Exbury in Hampshire, was born in London on the 10th of February, 1744. In his boyhood he spent some time at Oxford, kept at Chesham by an unknown Mr. Gilpin, who afterwards owed to him the living of Bolder. Ill health caused his removal from school about the age of fifteen; and it seems to have been with very insufficient punishment that he became a student in Pembroke Col- lage, Oxford. His time at the university was idly spent; and he left it without taking a degree. Perhaps the most im- portant influence exercised on his mind by his academical residence was derived from the romantic stories, and the adventures of adventure stories, and the adventures of adventure stories, of which he seems to have been particularly fond, and which he attended regularly. He studied law for a time in the Middle Temple, but found the study distasteful; and, having succeeded to the family estate in 1761, on his father's death, he at once abandoned the unprofitable profession, and went to the Continent. In 1766 Mr. Mitford married; and for seven years afterwards his time was chiefly spent in the retirement of his country-seat, where his early predilection for the Greek language and literature grew into a settled passion. In 1769 he became a captain in the South Hampshire militia, of which the historian Gibbon was then major; and the conversation and advice of Gibbon confirmed, if they did not prompt, his resolution to undertake a history of Greece. His first work, 'An Inquiry into the Principles of Harmony in Languages, and of the Mechanism of Verse, Modern and Ancient,' appeared in 1774, and was immediately followed by a translation of the 'Odyssey,' which he published in 1777. In 1778 he published 'A Treatise on the Military Force, and particularly the Militia, of this Kingdom.' In 1779 he lost his wife, and was himself seized with a dangerous illness, on recovery of which he was created a baronet from whose honours he never receded. Before leaving home he had become acquainted with the French scholars Voltaire and De Meusnier: the former introduced him to the Baron de Sainte Croix; and his intercourse with those two young students matured his own literary ambition. On his return home, however, he allowed public duties to claim frequent precedence. He acted as a county magistrate, and in 1778 was appointed Verderer of the New Forest. But notwithstanding his attachment to Gibbon was seduced to Gibbon's lieutenant-colonelcy in 1779, and in 1805 was appointed to the colonelcy, which he resigned in the course of the next year. From 1785 till 1790 he sat in the House of Commons as member for Newport in Cornwall; from 1796 till 1806 he represented Brearleton, a nomination borough of his maternal kinsman the Duke of Northumberland; and from 1812 till 1818 he was member for New Romney. His parliamentary appearances were confined to two or three speeches on the militia laws. In 1802 he succeeded, through his mother, to the Revelsy estates in Yorkshire. But his paternal estate on the borders of the New Forest was tenanted by the Mitford baronetcy residence. He died there on the 8th of February, 1827. His 'History of Greece' was written and published in successive portions under the dates of the first volume, being the following: vol. i., 1784 (second edition, 1790); vol. ii., 1786; vol. iii., 1797; vol. iv., 1808, and vol. v., 1818. It closes with the death of Alexander the Great; and the author, enfeebled by age and partly blind, was unable to execute his intention of continuing it to the subjugation of Greece by the Romans. In 1815 appeared an octavo edition of the volumes which had previously been published; and in 1829 there appeared a new edition of the whole work, in eight octavo volumes (since reprinted), with an introduction by his brother, Lord Redesdale, furnishing some particulars of the author's life, but chiefly taken up in vindicating the political opinions expressed in his 'History.' In 1829 appeared 'Mitford's History of the war between the Greeks and Philip of Macedonia. Philip is with him a perfect king, hero, and statesman. Demosthenes is a dishonest and malignant demagogue, and the Athenians are a contemptible and democracy miscreants. The works of the author have not been surpassed or matched by any modern or ancient historian. He has elucidated with remarkable success the state of political parties in some events. His political and personal views are lost in the general interest and partisanship which animates his mind. His work has not been neglected, but there is not a more accurate or more respectful view of many particular events. He has been led to these results mainly by his severely critical nature of estimating the antiquities, and by his systematic manner to gain his knowledge from contemporary sources.
secretes. Accordingly his history will always be valuable to the classical student, notwithstanding the bias above noticed, and in spite also of its deficiency both in philosophical reflection and in animation of narrative. In style indeed the work is a failure, as it is the regrettable fact that the last edition have removed only the least of the technical faults, the perverse affectation of the orthography. A treatise on the religions of Antient Greece and Rome, which he published late in life, in a small octavo volume, was regarded by him as a supplement to his History, and would probably have formed a part of it had he been able to complete his original design.

MODELLING. Modelling in clay is so completely a practical art, and depends so much on the experience and formative skill of the modeller, that beyond a few remarks on the necessary consistancy of the clay, nothing more can be given here than an account of the nature and uses of the tools, and some description of the sculptor’s process.

The tools, called modelling tools, are made of wood and wire, but no tool is more useful than the finger; indeed tools have been invented as mere aids to the fingers, and are designed only to do what they cannot perform. Wire tools are the most useful, being fashioned into lumps of various shapes and sizes, round and angular, and fixed into wooden handles. They vary not in their form, but drive the clay on to any already modelled part, the superfusious clay remaining in its place while the wire passes under it and until the tool is removed, when it either falls of its own weight, or is chiseled off. The skeleton of this modelling is created by the tools.

The wire tools are most efficient when applied to concave surfaces, especially those in the close or narrow folds of draperies: the wire is sometimes notched or indented, to give a rougher manner of application. Materials are made of box and ebony, of various shapes and sizes—curved, straight, pointed, rounded, and flat and broad; the broad tools being notchted, and designed chiefly for working the large convex masses of the figure. The drapery supports must be thick, for often the features, great nicety is required, and the modeller must be particularly careful not to injure what is already done, by retouching with the tool while clay is adhering to it, or be made ragged. The edges of the clay adhering clay will drive up the surface. A good method to guard against this accident is to keep the wooden tools which are used for the finer work soaked in oil; the clay is then not liable to adhere, and much time is accordingly saved in finishing the model. The above is perhaps, without practical demonstration, all that can be usefully said about the working tools.

The clay used is common potters’ clay, but should be of the best quality. It must be so wet that it will not stand in a mass much thicker than its own width without support. The clay adheres much more to the tools when wet, but it is at the same time hard to work, and under such circumstances the matter of great consequence, as the patience of the artist is less tried, and some expenditure of time is saved. The supports for the clay are a most important consideration, for if not of suitable nature, clay, even the finest, after a month’s or months’ labour, might suddenly fall to pieces by its own weight. This accident happened to Don José Alvarez, a celebrated Spanish sculptor, while at Paris. He modelled, about the year 1805, a colossal statue of Achilles receiving the fatal arrow into his heel, which, owing to the insufficient support of the clay, fell to pieces shortly after it was finished: it was much admired by the connoisseurs of Paris, but Alvarez had no courage, or wanted opportunity, to restore it.

This accident might certainly have been prevented by proper attention to the supports of the clay while the model was in progress, for though in large models this is a work of great care and labour, it is always practicable. The support of a figure of the heroic or ordinary size (seven feet) is comparatively easy, but this also exacts strict attention, especially if in any very active or unusual attitude. Sculptors generally model figures of the ordinary size upon a bench or stand called a banker, about thirty inches high, and about thirty inches square,—for a bust must of course be much higher; above this a solid circular plinth is fixed on a wooden box, and supports for any parts; and it is necessary to have two short slightly conical rollers, fixed to the plinth near the circumference: the plinth moves more easily on such rollers than wheels, and the rollers afford a more solid support and last much longer than diminutive ones. A banker should be so that the sculptor to see his work on all sides in any light, and it enables him to work on all parts, in one spot, or in the same light. On the centre of the plinth there must be fixed vertically a strong iron bar, about the height of a man, and from about six to ten inches in circumference, according to the weight of the figure; it must necessarily be strong and firmly fixed in the sand, to prevent the whole skeleton of supports. In loosely draped figures, which are particularly those which have the feet to fix a vertical beam of wood to the main iron bar; for though the bar will keep the clay perpendicularly in its place, it is no provision against the weight of a great mass; and the quantity used in some figures, even a moderate heroic figureases, or even a heroic male figure, the only amounts to about two tons. Two cross pieces of wood must be fixed to the main bar at the shoulders and the loins, from which the supports of the arms may be arched; and a third piece may be fixed in the middle to diminish the weight of clay; the supports of the legs must be bars, straight or bent, according to the position of the legs; but the supports of the arms, when not detached from the body or drapery, may generally be made of twisted thick corks, small pieces of wood being twisted in with it at short intervals and at right angles, like the pieces of paper in the tail of a boy’s kite. The fingers, if separated, will require surgical care; indeed the clay should be gradually built up against a complete skeleton of supports, and sufficiently strong not to yield in the least to the weight of the clay when the model is of this kind. In small fragments, the heroic size is often the work of a week or more, and it would be always advisable for the young sculptor, in modelling his first figure, to procure some experienced hand to construct it. If it be small, and the piece has to be detached and detached from the figure, the support might be so contrived as to allow the arm to be removed at pleasure, which would enable the sculptor to model the part beneath it more easily, and also to avoid the risk of injury to the arm. The contrivance is easily accomplished, for nothing more is required than a pipe or tube in the shoulder support, which could receive and hold firmly the arm, or large piece of wood, or metal; or merely thick or twisted wire, when of a small size. In modelling a bust very little support is necessary, an upright piece of wood with a cross bar at the shoulders being quite sufficient; but a small cross bar at the head would do no harm.

Another essential part of modelling is preserving the moisture of the clay, which should be always uniform if possible; it must never be allowed to dry, and it can be kept moist with very little trouble. While the modeller is at work, and the figure is exposed, especially in warm weather, he should repeatedly sprinkle it with water. A plasterer’s brush is the best instrument for this purpose, and much superior to a syringe or the mouth, which some sculptors formerly used to apply as a squat, even in the presence of their sitter, while modelling a bust: Nollekens, according to his biographer, said that it was a great mistake to use a syringe while modelling the bust of George III, and in the king’s presence. Bacon, on a similar occasion, used a silver syringe.

At night time, or when the artist is not at work on the model, it must be covered, but with a wet cover; the clay may be kept moist for a long period without adding water, provided the air be kept away from it; this may be done by an oil-silk or any air-proof bag, which can be made fast to the plinth of the banker by clay. Sculptors generally model flowing draperies from lay-figures. When the model is complete, the next process is to take the cast, to work the marble from, or to make other casts from. The whole model, while wet, must be covered, in two or three masses, or more if necessary, with plaster of Paris; when this is fixed and dry, the whole may be separated at the joints, without any regard to the preservation of the model, for when the mould is taken the model is no longer of any value. When the clay is completely removed from the mould, the component parts of the mould must be again put together, and in the place of the original clay it must be filled with plaster of Paris, and when the cast is well set, the mould may be broken up into fragments, and the cast is exposed, and complete, the finished work. If casts of it are required, a new working mould, or safe mould, as it is termed, must be taken, in which the model is exacted by water. The mould is then copied by the carvers, with the assistance of the point cutting machine, of which the most complete is that invented and used by W. C. Marshall, A.R.A. It is so contrived that it can be detached from the model in a very short time, with ease and nicety. It is always best to make the model of the size of the intended figure if practicable, because any error in
a small mode becomes multiplied in a larger one in proportion to the difference of size. Flaxman was in the habit of making small models, and he had in consequence sometimes immense labour to go through to diminish errors in the full-sized marble work: it is hardly possible to completely rectify these.

The antient sculptors used to bake their models, but this is not so good a plan as making plaster casts from them, though less troublesome and much cheaper: the clay in drying shrinks, and is apt to crack, and certainly never comes out of the oven the same shape that it was when put into it, or at least when originally modelled. These baked models are called terra-cotta (baked earth) figures, are extremely numerous, and are generally of small dimensions, but there are a few of a large size in various European museums. There are four at Naples which were found at Pompell; and the inferiority of these works is some proof of the advantage of the modern method of taking plaster casts from the models over the antient system of making them, for the errors in the proportions of these works are probably to a great extent due to the shrinking of the clay in the oven. The antients made also moulds of clay, which they likewise baked, and they formed their casts by the pressure of clay into these: this practice of pressing clay, or any malleable substance, into a mould is still occasionally found in some crude art, and is constantly in the potteries, and by frame-makers.

The antients used also wax for casting and in forming their models, especially those of the small bronzes, which are still so extremely rare, and the materials of which are goldsmiths and medallists. Modelling wax is prepared by melting virgin wax with a very small quantity of Venice turpentine and flake-white in fine powder: if coloured wax is required it is compounded with powdered colours, and melted with flake-white. The tools used in modelling in wax are made of wood and ivory, and have the same shapes as those of wood, already spoken of, for modelling in clay. Other processes in the art are sculpture of clay, being found in the articles BRONZE; FOUNDING; SCULPTURE, P. C.; and WAX MODELLING, P. C. S.

MODENA or MUTINA, TOMMASO DA, a painter of the fifteenth century, who has been described by some German writers, without any better foundation than the possession of some of his works, for Bohemia. He appears to have been at Prague in the time of the Emperor Charles IV., who was a patron of the arts, but it is also quite possible that the emperor bespoke the works in his possession of the painter at Modena. The name of Tommaso da Modena is no more important than it otherwise would have been on account of various pretensions which his works have given rise to. The altar-piece, in three compartments, of the Virgin and Child, with Saints Wenceslas and Palmatius, patrons of Bohemia, formerly at Carlstein, but now in the gallery of the Praga, was said to be by Von Mechel's catalogue, to have been painted in 1297; it was therefore eagerly sought after by writers of German and Italy, to confuse Vasari, to vindicate the title of their respective countrymen to the possession of the picture however bears no date, and more recent chemical analysis has shown that it is a tempera, and not an oil painting. The figures are half-length, about half the size of life, and are painted upon a gold ground; and the picture bears the following inscription:

Quis opus hoc factus? Thomas de Mutina piantis, Quale vide locate Barisini illius socior.

Von Mechel read Barisini, but some documents mentioned by Federici, Tiraboschi, and Lanzi show that Barisini should be the reading; Barisini being the name of Tommaso's father, and his own full name accordingly Tommaso da Barisino da Modena.

There is an extensive work, a series of many portraits, in the chapter-house of the Dominicans at Trevigi, which Fra Federici, a Dominician, has had engraved for his account of the antiquities of Trevigi—Memorie Trevigliane le Ope de Disegno.' They were painted in 1593, and are accompanied by the following inscription—Anno Domini MCCCLX. Fru Federici ordinis prepositus devoti ergo statuit Capitulum, et Thomam Pictor de Mutina pinit istud. These works are complete in the style of their time, but rather above the standard than otherwise.

BERENDUS, a Roman classical jurist, was apparently a pupil of Ulpian. He lived under the Emperor Alexander Severus, and was one of his legal ad-

visers (consiliarii); he also taught law to the younger Maximin (Jul. Capitol., Maximin. Jun. 1). Modestinsus often cites Ulpianus and Paulus. The Florentine Index enumerates the following works of Modestinsus: nineteen books of Excussiones, seven books of Excussiones, seven books of Poenae, and seven books of Differentiae. Six works of Excussiones, four books of Noemae. The work on Excussiones was written in Greek (Dig. 27, tit. 1, De Excussionibus). Nine other works of Modestinsus, in single books, are enumerated in the Florentine Index. The period of Modestinsus is also determined by an inscription, which contains the judgment in a suit which was prosecuted some time between 5037 and 5041. The inscription was first printed by Fabretti, in his work on Inscriptions (p. 278). Modestinsus is mentioned in a rescript, of the year a.d. 289, of the Emperor Gordianus. There are 345 excerpts from Modestinsus in the Digest.

The compilers of the Digest have made a few excerpts from two writers posterior to Modestinsus. These writers are Hermogenianus and Aurelius Arcadius Charisius. Modestinsus is cited by Charisius (Digest, 50, tit. 4, a. 18).

MODUS. (Thes. P. C.)

MOEHRINGIA, a genus of plants named after Paul Henry Gerhard Moehring, a German physician, author of 'Horus Himongen,' and other works on botany. It belongs to the natural order Caryophyllaceae, and has 5 sepals, 4 or 5 petals, either entire or slightly emarginate; 8 to 10 stamens, 2 or 3 styles, the capsule opening with 4 or 6 valves; the seeds numerous, rough; the plants annual. The species are alpine plants with the habitat of Arenaria. M. trinitis has ovate acute stalked 3-5-nerved leaves, the upper ones sessile, the petals shorter than the calyx, the styles longer than the stamens; found in the Alps of South Germany. Four other species of this genus are described by Koch in his 'Flora Germanica':—

M. maculosa, M. proca, M. polygonoides, and M. villosa.

The species are alpine plants, and adapted for cultivation on rockworks, being best grown in pots, by dividing them at the root. They are best grown in pots, in a mixture of sand, loam, and peat.

(Debogin's Manual; Don, Gardener's Dictionary.)

MOECHA, a genus of plants named after Conrad Moehnc, professor of botany at Marburg, who wrote several works on botany; amongst others, 'Enumeratio Plantarum Indigenarum Basii, presertim inferioris,' Cassel, 1777, 5vo.; also a work on the cultivation of North American forest-trees in Germany.

The genus Moenchia belongs to the natural order Caryophyllaceae, and has 4 erect sepals, 4 entire petals, 4 stamens, and a many-seeded ovary. It is a small glaucous plant growing in dry gravelly and sandy places.

(Debogin's Manual.)

MOI, or MOITE, or ARNAUD GUILLAUME, Chevalier, the son of the engraver P. E. Moitte, was a distinguished French sculptor, and was born at Paris, in 1747. He was first the pupil of Figal, after whose death he studied under Lemoine. In 1768 he obtained the grand prize in sculpture for a statue of David carrying the head of Goliath, and he went, as entitled in consequence, to complete his studies at the French Academy at Rome; the Roman climate however proved quite unfit for his constitution, and he was forced to return to Paris.

Motte has executed many excellent bas-reliefs and figures, and some equestrian statues; but he left many models, and among them his principal works, unfinished at his death, as the great bas-relief for the column of Boulogne, and the equestrian statue of General d'Hautpoul, a model in plaster, made for the French government. Moitte was a member of the old French Academy of Painting and Sculpture, and afterwards of the Institute of France, and a Chevalier of the Legion d'Honneur. He died in 1810.

The following are some of his principal works:—A marble statue of Cassini; another of General Custines; a baso-relief for the church of St. Vincent; a large relief for the church of St. Martin. He was also a pupil of Vassilievo in the court of the Lorraine, representing History in

scribing 'An VI. and the name of Napoleon with his French

MOLNY, a genus of grasses belonging to the tribe Festucceae. It has unequal glumes without lateral ribs, shorter than the lanceolate and pointed lemma, and a subulate rudiment of another. The palea hardening on the loose fruit, and the style terminal. There is one species which is British—

*M. oreades*, which has an erect elongate narrow panicle, spikelets from 1- to 3-flowered; the outer pales rarely 5-nerved, downy, the upper part of the stem naked. The leaves are long, linear, and alternated. It grows on wet heaths in alpine situations. This species is the *M. deperdaurus* of Lindley.

(Babington, Manual of British Botany.)

MOLY, PIETER. [Tamusfera, P. C. S.]

MOLYNA, GRASS, *P. C. S.*

MONCREIF, SIR HENRY, a divine, and ecclesiastical leader in the church of Scotland, was born at Blackford, in Perthshire, on the 8th of February, 1760. His father Sir William Moncreif, was a prominent member for one another quarter of a century before the baronetcy by the failure of the elder line, when he was minister of Blackford, in 1744. Sir Henry was the sixth of his family that had belonged to the clerical profession. He studied at St. Andrew's College, and was ordained a minister on the 16th of August, 1771. Though he was probably the only man of rank who ministered in the church of Scotland, he was as strongly imbued with the spirit of the Presbyterian policy as those, by far the most numerous class in that church, whom the profession was the means of raising from the more humble grades of society. He had a commanding appearance, was gifted with a powerful argumentative faculty, of a kind of wit, and learned and with such advantages, personal and social, he naturally occupied the first rank in the church. He was for some time his father's successor as minister of Blackford, and in 1775 he was appointed to the charge of St. Cuthbert's, in Edinburgh, where he remained till his death on the 14th of June, 1837. He was frequently moderator of the General Assembly, and his name was conspicuous in nearly all the ecclesiastical discussions connected with the church of Scotland during his minister in Edinburgh. He was the author of many pamphlets connected with these questions. In 1815 he published 'Discourses on the Evidence of the Jewish and Christian Revelations, with Notes and a Preface, by the Rev. John. S. Elliott.' Also 12,000 lines entitled "Writings of Dr. John Erskine." [ERKINE, JOHN, P. C. S.]

MONESES (from μονή, sole, or alone), a genus of plants belonging to the natural order Ericaceae and the tribe Pyrole. It has 6-toothed calyx; 5-lobed corolla; 10 inclined stamens; the anthers dehiscing at the base by two holes, the cells elongated and tubular; the stigma 6-toothed; the capsule 6-celled; the valves dehiscing from the apex, destiné to toothment. There is but one species of this genus, *M. grandiflora.* It has a creeping root; large solitary terminal drooping open white flowers, nearly an inch broad; very large stigmas. It is a native of Europe, Asia, and North America, in Alpine moor and woods. It is found in Great Britain, in the mountainous woods of Scotland. It may be cultivated in the same manner as the species of *Pyrola.* [WINTERGREEN, P. C. S.]

MONEY is the medium of exchange by which the value of commodities is estimated, and is at once the representative and equivalent of such value. Barter is naturally the first form in which any commodities can be exchanged. Exchanges of the one by the other, is equal, and the same article than he requires for his own use, exchanges a part of it for some other article which he desires to possess. But this simple form of exchange is adapted to a rude state of society only, where the objects of exchange are not numerous, and where their value has not been ascertained with precision. As soon as the relations of civilized life are established in a community, some medium of exchange becomes necessary. Objects of every variety are bought and sold, the production of which requires various amounts of labour; these at different times are relatively abundant or scarce; labour is bargained for as well as its products; and at length the exchangeable value of things, related to labour, is distinctly defined, and needs some common standard or measure by which it may be expressed or known. It is not sufficient to know that a given quantity of corn will exchange for a given quantity of a commodity; for, their value is always the same; but if a standard is established by which each can be measured, their relative value can always be ascertained as well as their positive value, independently of each other.

As a measure of value only money is thus a most important auxiliary of commerce. One commodity from its nature must be measured by its weight, another by its length, a third by its cubic contents, others by their number. The diversity of their nature, therefore, makes it impossible to apply one description of measure to their several quantities; but the denomination of the value of each may be measured by one standard common to all. Until such a standard has been agreed upon, the difficulties of any extensive commerce are insurmountable. One man may have nothing but corn to offer for other commodities, the owners of which have somewhat of a different quantity of corn which would be equivalent for their respective goods. To effect an exchange these parties would either have to guess what quantity of each kind of goods might justly be exchanged for an equivalent of 10 bushels of corn, or one another, which proceeded to the baronetcy by the failure of the elder line, when he was minister of Blackford, in 1744. Sir Henry was the sixth of his family that had belonged to the clerical profession. He studied at St. Andrew's College, and was ordained a minister on the 16th of August, 1771. Though he was probably the only man of rank who ministered in the church of Scotland, he was as strongly imbued with the spirit of the Presbyterian policy as those, by far the most numerous class in that church, whom the profession was the means of raising from the more humble grades of society. He had a commanding appearance, was gifted with a powerful argumentative faculty, of a kind of wit, and learned and with such advantages, personal and social, he naturally occupied the first rank in the church. He was for some time his father's successor as minister of Blackford, and in 1775 he was appointed to the charge of St. Cuthbert's, in Edinburgh, where he remained till his death on the 14th of June, 1837. He was frequently moderator of the General Assembly, and his name was conspicuous in nearly all the ecclesiastical discussions connected with the church of Scotland during his minister in Edinburgh. He was the author of many pamphlets connected with these questions. In 1815 he published 'Discourses on the Evidence of the Jewish and Christian Revelations, with Notes and a Preface, by the Rev. John. S. Elliott.' Also 12,000 lines entitled "Writings of Dr. John Erskine." [ERKINE, JOHN, P. C. S.]

HIS Sermons, of which there had been some separate publications during his life, were collectively published after his death by scholar with such advantages, personal and social, he naturally occupied the first rank in the church. He was for some time his father's successor as minister of Blackford, and in 1775 he was appointed to the charge of St. Cuthbert's, in Edinburgh, where he remained till his death on the 14th of June, 1837. He was frequently moderator of the General Assembly, and his name was conspicuous in nearly all the ecclesiastical discussions connected with the church of Scotland during his minister in Edinburgh. He was the author of many pamphlets connected with these questions. In 1815 he published 'Discourses on the Evidence of the Jewish and Christian Revelations, with Notes and a Preface, by the Rev. John. S. Elliott.' Also 12,000 lines entitled "Writings of Dr. John Erskine." [ERKINE, JOHN, P. C. S.]
barter gives place to commerce. But what must be the qualities of a medium? Are all commodities used in a barter and its products of their own labour? Is it now no longer like a weight or measure, the mere instrument for assessing the value of commodities; but, to use the words of Locke, ‘it is the standard of value’? It is the measure of the largeness of the largeness of the larger. A bargain is complete when money has been paid for goods; it has no reference to the price of other goods, nor to any circumstance whatever. One party parts with his goods, the other pays his money as an absolute equivalent. But though money as a medium of exchange thus differs from money as a mere standard of value yet in both characters it should possess, if it be possible, one quality above all others—an invariable equality of value, applicable at all times and in all circumstances. As a measure of value it is essential that it should always be the same, as that a yard should always be of the same length. And unless, as a medium of exchange, its value be always the same, all bargains are disturbed. He who gives his labour or his goods to another in exchange for a delusive denomination of value instead of for a full equivalent which he expects to receive, is as much defrauded as one who should bargain for a yard of cloth and receive short measure.

But however desirable may be the invarableness of money, complete uniformity of value is an impossibility. There is no character which would be disturbed. All descriptions of measurements correspond with absolute qualities, such as length, weight, and number, and may be invariable. But as value is a relative and not an absolute quality, it can have no invariable measurements between money and commodities. The value of all commodities is continually changing; some more and some less than others. Their real value depends upon the quantity of labour expended upon them; but temporary variations in their exchangeable value are caused by abundance or scarcity—by the relations which subsist between supply and demand. No commodity yet discovered is exempt from the laws which affect all others. If precisely the same quantity of labour were required for a long series of years to produce equal quantities of all commodities, its real value would remain unchanged; but if it were at the same time an object of demand amongst men, variations in the proportion between its supply and the demand for it would affect its exchangeable value. It follows therefore, that to be an invariable standard, money must always be produced by the same amount of labour, and in such quantities as shall constantly bear the same proportion to the demand for it.

But even if any description of money could be invented which possessed these extraordinary qualities, the value of all other articles would still be variable, and thus its representa- tive character would be disturbed. At one time, for example, a given denomination of money would represent a certain number of bushels of wheat; at another time, the same money, unchanged in real value or in demand, would represent a much greater quantity. The supply of money, a by-product of skill and of experience of mankind, facilitates production, and by saving labour reduces the real value of commodities. Their value is also liable to temporary depreciation, as happens whenever a foreign article, for instance, is imported upon an insufficient demand. But if money maintain the same value, in relation to itself, notwithstanding the diminished value of other articles, its proportionate value is practically increasing. The consequences of a growing disproportion between the representative value of money and the value of commodities are these: 1st, a producer has to give a larger quantity of his goods than before for the same amount of money; 2dly, those who are entitled to payments in money, receive the value of a greater quantity of commodities than they would have received if the relative value of money and commodities were of the same magnitude. In these circumstances, that, as a general rule, all creditors whose debts have been calculated in money derive advantage from any increase in its value relatively to commodities; while debtors benefit from any circumstance which raises the value of commodities as compared with that of money, whether it be by increasing the value of the former, or by depreciating the value of the latter. To make these principles clear, it must be supposed that a handsome farmer, who has considerable standing crops of wheat, has entered into a contract with his landlord, that the value of money has been relatively increased. In order to pay his rent, he must now sell a larger proportion of his produce, even though its gross production has not increased. Or a manufacturer, on the other hand, his landlord receives the same money rent, but is able to purchase more commodities than before on account of the increased comparative value of money.

Thus far we have been content to confine ourselves to the abstract qualities and uses of money, and to explain such general principles only as are introductory to the consideration of particular kinds of money, and of the modes of using and regulating them.

In all ages of the world, and in nearly all countries, me- tals seem to have been used, as it were by common consent, to serve the purposes of money. It is true that other articles have also been used for this purpose, such as shells among certain highly civilized nations, and cowrie shells in the less civil- ized parts of Africa; but in all such portion of the currency has been and is composed of metals. We read of metals amongst the Jews, the Chinese, the Egyptians, the Persians, the Greeks, the Romans. In the earliest annals of commerce they are spoken of as objects of value and of exchange; and wherever commerce is carried on there they are still used as money. But as they were introduced for this purpose in very remote times, it is not probable that they were selected because their value was supposed to be less variable than that of other com- modities. More than two thousand years ago, indeed, Aries- totle saw the limits of the use of silver and of gold, and he thought that the principal use of metallic money was that its value was less fluctuating than that of most other substances (Eth. Nicom. v. 6). But however clearly this great philosopher may have observed the general tendency of the circulation of metals, he could not have predicted the circulation of metals, those who first used them were men engaged in common barter, who considered their own conveni- ence and security without reference to any general objects of public utility. They must have used metals not as a standard of value, but as an article of exchange, which facilitated their barter. All metals are of great utility and have always been sought with eagerness for various purposes of use and ornament; but they were not used as money until their use was facilitated by the circulation of metals, which first engaged them in common barter.

Their comparative scarcity, the difficulty and labour of procuring them, their extraordinary beauty, their singular purity, their adaptation to purposes of art, of luxury, and display; their durability and compactness; must all have contributed to render them most suitable objects of exchange. They were easily conveyed from place to place; a small quantity would obtain large supplies of other articles; they were cer- tain to find a market; none would refuse to accept articles in payment which they could immediately transfer to others; and thus gold and silver naturally became articles of com- merce, readily exchangeable for all other articles, before they were considered as money, and were acknowledged as such by law and custom.

The transition of the precious metals from the condition of mere articles of exchange, amongst many others, to that of a recognized standard of value, is a by-product of certain conditions of skill and of experience of mankind, facilitates production, and by saving labour reduces the real value of commodities. Their value is also liable to temporary depreciation, as happens whenever a foreign article, for instance, is imported upon an insufficient demand. But if money maintain the same value, in relation to itself, notwithstanding the diminished value of other articles, its proportionate value is practically increasing. The consequences of a growing disproportion between the representative value of money and the value of commodities are these: 1st, a producer has to give a larger quantity of his goods than before for the same amount of money; 2dly, those who are entitled to payments in money, receive the value of a greater quantity of commodities than they would have received if the relative value of money and commodities were of the same magnitude. In these circumstances, that, as a general rule, all creditors whose debts have been calculated in money derive advantage from any increase in its value relatively to commodities; while debtors benefit from any circumstance which raises the value of commodities as compared with that of money, whether it be by increasing the value of the former, or by depreciating the value of the latter. To make these principles clear, it must be supposed that a handsome farmer, who has considerable standing crops of wheat, has entered into a contract with his landlord, that the value of money has been relatively increased. In order to pay his rent, he must

...
they distinguishable in character from any other articles of exchange. They were weighed, and being of the required fineness, a given weight was known as a denomination of value, but in the same manner only as the value of a bushel of wheat may be known. In the earliest ages gold and silver seem to have been internally exchangeable, and valued by weight and fineness only. The same custom exists at the present day in China. There is no silver coinage, but the smallest payments, if not made in the copper tokens, are effected by exact weighing always the same amount liable to permanent alterations, and also to occasional fluctuation.

Both gold and silver are alike subject to these general laws, and are therefore imperfect standards of value. If one be the standard independence of the other, being by itself, and also in its relation to other commodities; if both be adopted as standards at the same time, they will not only vary in themselves, and in relation to other commodities, but they will vary also in regard to each other. And thus another element of uncertainty is introduced into the coinage, which becomes still more imperfect as a standard.

But it is not customary for the state to allow coins to fluctuate in their legal value according to the circumstances which determine the market prices of gold and silver. Coinage does not merely authenticate the weight and fineness of a piece of metal, but is also intended for the same purpose for other commodities; but it attaches to it a definite value by fixing the standard price of the metal as well as the weight and fineness of the coin. The object of this regulation is to maintain the standard of value, and to prevent any small fluctuations in the value of the precious metals, it will generally have that effect. But if any considerable disproportion should arise between the standard price of bullion and the market price of the coin, a change in the standard will necessarily take place. If the market price should become considerably higher than the standard price, the coins would be melted down for the sake of the profit arising from the difference. If it should become considerably lower for any length of time, the value of the coin, though nominally unchanged, would in fact be depreciated; for they would exchange for a less quantity of other commodities than they exchanged before, and thus a currency composed exclusively of metals cannot be made an accurate standard of value by any expedients of law.

We may here remark however, that a seignorage, or charge by government to cover the expenses of coinage, acts as a protection, within certain limits, against the melting of coins, because unless their value be depreciated by over-issue, the whole charge will be added to their value as coins, and will be lost when they are melted. For amongst other reasons a seignorage should always be charged by the state.

There is yet another imperfection in coins as standards of value. Notwithstanding their natural durability, they are subject to continued and frequent depreciation in value. They are also exposed to the fraudulent exertions of men whose trade it is to rob them of a portion of their weight by artificial wear. The value of coins is therefore naturally reduced by the loss of weight, apart from any other causes of variation.

From all these circumstances it is evident that gold and silver coins have qualities inherent in them which render them necessarily imperfect standards of value, with whatever care and skill they may be regulated. But, in addition to these natural causes of imperfection, others have been artificially produced by erroneous or dishonest political expedients. There is no country perhaps in which the coinage has never been debased by the government. Debasement of coins was formerly a common artifice for increasing the revenue of states, and it has been effected in three different ways:—1, by diminishing the weight of the gold and silver coins; 2, raising their nominal value and ordaining that they shall pass current at a higher rate; and, 3, by debasing the metal itself. Of these the latter is the most general, and the most effective, since it has not only reduced the quantity of pure metal and increasing the quantity of alloy. In all these ways the coins of England have been debased at different periods; and it was the great experiment to which they were subjected by the late ministry, that from the Conquest to the reign of Queen Elizabeth the total debasements of the silver coins have been estimated at 14 shillings per cent. (Clifford, 1816, vol. i. p. 86.) By expedients of an opposite character the standard of coinage was raised, and the result of measures connected with the coinage of this country was, that in a period of 116
years, from the 1st James I. to the 1st George I., the value of gold coins, as compared with silver coins, was raised 39 per cent. (Ibid., p. 84.) No further examples are needed to prove the inconstancy of coins as a standard, when they form the value of gold.

But notwithstanding these imperfections, the convenience of gold or silver coinage, as money, has led to the universal adoption of one or the other, or of both conjointly, as the standard of value. The objections to a double standard have already been noticed; but throughout a long period of the history of this country we find gold and silver prevailing equally as standards. There appears to have been no public coinage of gold at the royal mints prior to the 41st Henry III. The gold pennies coined at that time were expressly declared not to be a legal tender, and never obtained a very general circulation. Silver was then the universal medium of exchange, and the people were unacustomed to the use of gold as money: but as their commerce and riches increased gold naturally became more convenient for large payments. The results of this progress became apparent in the reign of Edward I., who established a general circulation of gold coins, which, though partially introduced nearly a hundred years before, by Henry III., had not been continued by his successors. From this time gold and silver coins circulated together with legal tenders. To what an extent their relative value varied at different periods, has already been noticed; but they were equally recognised by law as authorised standards of value in all payments whatever, until the 53d Geo. III. c. 42 that, in future, silver coins should not be a legal tender in payment of any sum exceeding 25l., except according to their value by weight, at the rate of 5s. 2d. an ounce. This was temporary; but by what manner or means; several statutes until the year 1816, when the legal tender of silver coins was further restricted to payments not exceeding forty shillings (56 Geo. III. c. 69). And thus, as all large payments were made and calculated in gold coins, they became the sole standard of value, so far as coinage alone was the real medium of exchange.

The expediency of adopting gold as the standard instead of silver, has been the subject of much talk and controversy amongst the highest authorities upon monetary affairs. It was the opinion of Locke, of Harris, and Sir William Petty (all great authorities) that silver was the general money of account in England, and the measure of value in its commercial dealings with other countries. Its general adoption for such purposes was urged as a proof of its superiority as money over gold; and of this opinion are many thinkers of high authority; at the present day. On the other hand it has been argued, that the metal of which the chief medium of exchange is fabricated, should have reference to the wealth and commerce of the country for which it is intended; that copper or silver coins cannot be considered the cheapest means for the convenience of a very poor country; but that as a country advances in wealth its commercial transactions are more costly and require coins of corresponding value. As a matter of convenience, the payment of a debt is the standard in England; silver is the standard in France; and the comparative facility of effecting large payments in the current coins of the two countries can admit of little doubt. Habit will familiarise the use of silver, and render a people insensible to its inconvenience; but it is certain that in England fifty sovereigns can be carried about in a man's waistcoat pocket, while in France the value of that sum in silver would weigh about 48 lbs. troy; so heavy and bulky indeed would it be, that a carriage would be required to convey it from one part of Paris to another.

But the convenience of coin for a certain class of payments is a question quite distinct from that of its fitness for a standard of value. It is not necessary to exclude gold from the coinage because it is not adopted as the standard; it may be circulated as freely as the people desire to use it, while, instead of being the legal standard, its value may be calculated in silver. If silver be the standard, a large gold coinage may circulate at the same time for the convenience of larger payments, just as silver circulates for small payments wherever gold is the standard. In either case, under these circumstances the state is left to the lawful standard governs all calculations and bargains, while the other metal merely conforms to its standard, and is subsidiary to it. But even if the relative convenience of gold or silver as a medium of exchange were well understood, it could not be determined by the modes of effecting large payments only. All payments are calculated as easily in the coins of one metal as of another, in whatever form they may be actually effected. But by far the greater number of bargains are made for articles of small value. It is in silver and copper that the consumption of all commodities is mainly paid for. The wages of labour and the payments for small quantities, and in that form the prices of nearly all the ordinary articles of daily use are calculated. However the wholesale bargains of merchants may be conducted, the goods bought and sold by them are ultimately distributed to the consumers in small quantities, the prices of which are estimated in silver and copper. The aggregate value of the small bargains must be equal to that of large mercantile bargains which relate to the internal trade of individuals; and the sum of small quantities, the number they are beyond all comparison more important. It is certain also that in the vast operations of commerce the bargains, in whatever medium they may be calculated, are very rarely paid for in any coin whatever, but are settled by various forms of credit; while all minor transactions—the bargains of daily life—can be adjusted by money payments only. It is for such purposes therefore that the metallic currency of a country is mainly needed: and it may be contended with much force that silver represents the value of commodities more universally than gold, and is consequently a fitter standard.

The notion of a standard however cannot be determined solely by considerations of convenience; for we must chiefly regard its intrinsic qualities as a permanent measure of value. How shall uniformity of value be maintained as far as practicable for all the commodities it is in use? How is this main question to be determined; and not, Which is the most convenient form in which to make bargains? In what medium shall the whole property of the country be valued, from one year to another? How shall commodities be transferred from one hand to another prepared? How shall fluctuations be restrained in the value of this standard itself? These are the questions to be answered.

In favour of gold as a standard it is argued that being less extensively used for places and other manufactures, it is less an article of commerce than silver, and is therefore made more specifically to the purposes of money. On the other hand, it is contended that gold is used in large quantities for jewellery, coins, and ornaments; and, being infrequently, and particularly scarce material, its consumption in this manner affects its quantity and value to a greater extent than the use of plate affects the price of silver. And in this argument there is much weight, for it is estimated that the quantity of gold compared with the quantity of silver is as 1 to 50; and their relative value is as 1 to 15. (See Bullion Report, 1819, Allen's Evidence.) Now it is evident that any variation in the commercial demand for gold must be more sensibly felt than a similar variation in the demand for silver.

But it is not sufficient to consider the demand for the precious metals as articles of consumption only; they are suddenly sought for in large quantities to confuse the exchanges and drain away a country's resources. If the exchanges be unfavourable to a country, its precious metals are in greater demand for exportation than its commodities; or if there be a foreign war, its metals are in demand for the purchase of the necessary supplies. In time of war the precautions even other countries in the distribution of their resources. Here again gold must feel the demand to a greater extent than silver. If metals be required for exportation in payment of goods, gold is sure to be preferred by merchants; it is compact and portable; a large value can be exported at small cost and without difficulty; while fifteen times as much silver must be taken to effect the same purpose. In war gold is even more in request than for the purposes of commerce: its facility of transport is so important that it must be obtained at any cost, and it is consequently drained from all countries in which it can be found. Thus not only is gold, from its limited quantity, more sensibly affected by any increased demand than silver, but it is more peculiarly liable to be drained from a country to another: and this is the great and sudden drain of any country in which it forms the standard of value.

If it should happen that one country has a large gold coinage in circulation and in use for the purposes of commerce, while all the adjacent countries use a silver currency, and possess very little more gold than is necessary for its consumption, it is clear that whenever a large demand is suddenly made for goods, this country, which is in a currency. That country will be immediately used by all others as a rich gold mine, whence abundance of metal without alloy, and assayed ready to their hands, may at once be granted, without digging any new ore.
in the earth. No laws and no vigilance can restrain its export; as soon as it is wanted abroad, it disappears like water through a sieve. And this has been the case with England. Every other country in Europe has a silver standard; and whenever a country attempts to exchange for it foreign exchanges are unfavourable may be estimated from the returns of bullion retained by the Bank at different periods. On the 28th February, 1854, the Bank had in its coffers 19,810,000l. of bullion; at the same period, in 1825, it had 8,779,100l.; on the 31st August in that year its treasure was reduced to 8,634,924l.; and on the 28th February, 1829, to 2,459,510l. In the same note, the greater part of this money was the result of specie brought to the Bank, and but was reduced by the following February to 5,938,750l. A similar exhaustion of treasure was exhibited in 1838-9. In December, 1838, the Bank possessed 9,686,000l. of bullion; and in August, 1839, no more than 3,444,000l. These are undoubtedly very strong objections to a gold standard, and in order to test them thoroughly it would be satisfactory to compare the actual prices of gold and silver, and estimate their relative variations. But such comparisons are extremely defective, for there is no common standard by which to compare the price of each metal. If silver be purchased with gold, how shall we determine in which there has been an exchange? In the first place, the effect of the exchange is not the same. At the same price as with bank notes, there is a standard wanting; for the notes are made to conform to the value of the gold, and not to the value of the silver. These elements of uncertainty make it impossible to compare the prices of the two metals. The result of the exchange is, in fact, a purchase of the silver bullion, and upon them, the fluctuations in the prices of silver bullion would appear to be very slightly greater than those of gold. (See Bank Charter Report, 1692; see Paper, No. 722, App. p. 91.) This result does not corroborate the objections to a gold standard, but it must be recollected that, independently of fluctuations in the prices of bullion, a diminution in the quantity of money circulating in a country raises the value of the remainder, and disturb its relation to the prices of other commodities. It is in this form that the effects of an abstraction of gold must be felt rather than in the price of gold, and those who have to deal with the money of a country, or who are engaged in speculating, can only be affected with the money, and are not always perceptible. If a country had a circulation composed exclusively of gold, it might sometimes be deprived of all its money; if of gold and silver conjointly, it might sometimes be deprived of all its gold; but no country could be deprived of all or nearly all its silver by the operations of commerce. When paper money is added to gold and silver coins as part of the circulation, a country can always command a sufficient quantity of money; but the drain of its metals has an important influence upon the value of its circulating medium, and upon the operations of commerce; but of these matters more will be said hereafter.

The consumption of the precious metals as standards of value have now been adverted to. Both of them are less liable to variation than any other known commodity which could be used for the purpose of money; but of the two, the bullion of silver is more useful upon the whole, the most suitable for a standard of value. But whatever metal may be chiefly used as money, there is a disadvantage attending the circulation of coins which remains to be noticed. To maintain a large circulation of coins is the most expensive mode of furnishing a people with a medium of exchange. In the first place the whole value of the metals of which they are composed is subtracted from the productive capital of the country, in order to facilitate the exchange of other commodities. Unless this expense be absolutely necessary, it is an unwarrantable extravagance. It is as if children should play at cards with gold counters instead of ivory fish. Secondly, the wear and abrasion of coins makes it necessary to supply their deficiency with more of these costly metals, in addition to the amount already coined. Thirdly, not only are coins diminished in weight, but great numbers are irretrievably lost and destroyed. They are buried in the earth by miners, and never found again; they are lost in the sea; they are wasted by fire; they are dropped in the roads, and trampled under foot with the dust and stones. Everything, they may be destroyed by the want of the country, and wastes the products of its labour. Some cheaper kind of money therefore should, as far as possible, be used as a substitute for gold and silver; and such a substitute has been found in paper money.

Not only is paper more economical than gold and silver, but it is more convenient than either for effecting large pay-
the country in which it is issued; but it differs from gold and silver, inasmuch as it cannot serve the purposes of an international currency. Gold and silver are current all over the world, and their value is everywhere understood; but paper-money is necessarily confined to the purposes of internal circulation.

2. Promissory notes issued by bankers or other persons unconnected with the state, not being a legal tender, may be refused in payment of any debt. They can only be circu-
late-1, therefore, with the entire concurrence of those who receive them. It is by means of banking accommodations, however, that they usually get first into circulation. A per-
son who wishes to borrow money, if he is very particular concerning the form in which he obtains it, and he willingly accepts a note, if it be offered him instead of gold. He pro-
bably owes money to another, to whom he, in turn, offers the note as payment. This third party will readily accept it, for he wishes to secure the payment of the debt, and if he distrust the value of the note, he may immediately call upon the party who issued it, for gold. When the credit and sol-
veney of a bank are well known in any neighbourhood, its notes pass from hand to hand without any distrust, but they rarely circulate beyond the adjacent district. Within its own district they are received as money, as readily as a state banknote, and beyond its district, if the bank is known, they are sure to be returned for gold, just as a Bank of Eng-
land note would be returned from Russia. A bank of issue is also a bank of deposit, and the people amongst whom its notes are the best known are the most precise in the habits in which they issue them; and receive credit for them—not as notes only, but as current money: and when they draw again upon their deposits, they may receive the amount in gold and silver or in state bank-
notes only; not as the distinction between local and other descriptions of money is gradually lost sight of; they are readily convertible: they are universally circulated: habit familiarises the use of them; and at length, without the sanction of protection in any way, they become money: they are gold, and not the state, has coined them. Still any one may refuse to receive them, and the extent of their circulation depends upon the credit of the issuer. Let a whisper be heard against his honesty, or his single day not be returned to him for immediate payment in the currency of the state.

The circumstances which occasion a large circulation of both these kinds of paper-money in a country are, the convenience of such a circulation, and the difficulty of obtaining a sufficient coinage for effecting the various purposes for which money is used. The demand for money is continually increasing in proportion to the increase of commodities in quantity and value; and in a rapidly improving country no coinage can keep pace with such an increase. When paper-
money is issued it does not supersede gold and silver, but is used with them, and in the ratio of the latter. Its destruction is not, therefore, of the same as that of the coins; and if it be a properly regulated currency, its value will be precisely as large as that of the coins of a denomination. A hundred pound note is of as much money in the hands of a banker or sovereign as one of a hundred pounds in the hands of a sovereign. But how is this equality of value to be maintained between two descriptions of money differing so materially in character? Gold and silver, as already explained, have a known value as articles of commerce, and their value depends upon the quantity of labour required for their production. If this continue unchanged for many years, their exchangeable value may still be liable to fluctuation by reason of varying proportions of supply and demand. The supply of them may be the same with an increased demand; or the demand may remain the same, and the supply be either increased or diminished. But paper has scarcely any real value when used as money: the labour expended upon it compared with its denomination of value is merely nominal: and its value, supposing its credit to be good, must therefore depend entirely upon the proportion which the quantity of it bears to the requirements of commerce. If less be issued than there is a demand for, its value will rise; if it be issued in excess, its value will depreciate. So strong is the operation of this principle, that promissory notes, which are legal tender, are raised from the value of gold, though inconverible into specie, if their amount be suffi-
ciently limited. This result was actually produced, after the suspension of specie payments in 1792; when, so far from being a cause of the bankruptcy of the currency and the depreciated paper-money, a premium over gold, until they were issued in excess, and fell to a discount. It is evident, therefore, that the value of paper-money is independent of convertibility. If convertible, but issued in excess, its value will be depreciated; if inconverible, but limited in amount, its value will be sustained. And further, if government paper and local notes be concurrently in cir-
culation, as is the case when they are issued in excess, if both are to be depreciated, because the aggregate quantity of paper-money will be increased beyond the demand for it.

The mode of regulating the issue of paper-money so as to sustain its value and to prevent it from fluctuations which are those difficult problems which have perplexed theorists and statesmen, and still remain to be completely elucidated by experience; but the principles upon which any sound system of paper-currency must be founded are now agreed upon by the best authorities.

Let it be supposed that no paper-money is in circulation but government notes are; and let the paper-money be convertible into specie, and that it is the desire of government to maintain them at the same value as the gold and silver coinage. By what principle could the issue be regulated so as to effect this object? Gold and silver maintain a reasonable steadiness of price, as they are possessed of a real value, and being in demand all over the world, are distributed in quantities proportioned to the wants of each country. Without any standard price being fixed by the state, their value will, therefore, be self-regulated; but gold and silver are of any real value, has no element of stability in itself, and unless its issue is adjusted with the utmost nicety, its value will be constantly fluctuating. As the object to be secured is an equality of value between gold and silver, the precise amount of paper-money is an element of stability which is wanting in the latter, it is clear that paper-money must be made, in some manner, to conform to the value of the precious metals. Now this can only be done by converting it back into gold or silver, whenever its holders demand such a con-
version.

To regulate the issues of inconverible paper money is like filling a vessel with water in the dark, and without a measure: it is by the over and under issue that it is supposed to fall; while a convertible paper, under proper regulation, adjusts itself to the standard of the precious metals.

If convertibility is desirable when there is no other paper in circulation, then issues may be limited, or it is in-
convenient when promissory notes are permitted to be issued by other parties; for, in that case, it is necessary to guard against an excessive issue of both descriptions of paper; and when government paper is issued, other issues of paper will in some degree conform to its standard, as it, in its turn, con-
forms to that of the precious metals.

The manner in which convertibility restrains the over-issue of notes may be thus explained. If too much money be in circulation, its value is depressed, and the prices of commodities relatively raised. It thus becomes more profitable to export money than commodities in payment of the price of imports. But exports of precious metals or of any real value, has no element of stability in itself, and unless its issue is adjusted to the standard metal. If it be the sole or chief bank of issue, it will be the prin-
cipal depository of bullion in the country; and thus any drain caused by unfavourable exchanges will be first and chiefly felt by it. Persons wishing to export bullion will demand it of the bank in exchange for notes. In this way the bank is apprised of the state of the foreign exchanges, and learns that money is too abundant; while it has the power of immediately contracting its circulation by means of this very demand for bullion. It has merely to lock up those notes which it has received back in exchange for bullion, and every exportation of its bank-notes and imports from abroad reduces the quantity and restores the exchanges to a healthy state, by ad-
justing the quantity of money to the requirements of commerce. This is a simple mode of regulating the circulation of paper-money in a country, and upon which all the paper-money of any body only, it could not fail to be effectual. So far as the principle has been tested in England it has been successful; but its operation has been interfered with by the competing interests of banks and independent bankers, who have carried on the banking business with the issue of notes, in the bank itself.

Both those causes of disturbance have been partially provided against by the recent Bank Charter Act (7 & 8 Vict. s. 92), and the Bank of England of a few years ago, which extinguished any imperfection in the principle, that the paper-circulation of the country must be regulated by the foreign exchanges.

Any further reference to the particular laws and practice
by which the circulation of this country is regulated, in connection with a complicated system of banking, will be unnecessary for the explanation of principles, and these matters have already been considered. [3] But we cannot quit the subject of convertibility without advert- ing to a point of great import. In order to regulate the issues of paper with reference to the exchanges, it is by no means necessary that the issuing body should be given the power to give bullion in exchange for its notes, at the standard price, whenever a certain amount should be demanded. There can be no object in giving facilities to every person who possesses a 2d note, to receive gold or silver, and much mischief is caused by such facilities, in times of panic; while, on the other hand, no impediment would be offered to the great operations of commerce by raising the minimum quantity of bullion to be demanded. By this arrangement whenever notes fell below the value of bullion, they would be brought in exchange for it, until the prices of both were again equalized; and if, by any undue limitation of issue, the value of notes should be raised above that of bullion, the bank should be obliged to give its notes in exchange for bullion. In this manner the circulation would be enlarged and the equilibrium between the two would be maintained. The proposition was again made by the late Mr. Ricardo in his able pamphlet entitled "Proposals for an Economical and Safe Currency," and was carried into effect, for a short period, on the resumption of specie payments; but it was succeeded by the present plan of convertibility into gold coin, which is more costly and less secure in its operation.

In regard to the issue of paper-money there are two conti- nental theories, which remain to be noticed, although it will be impossible to enter fully into the arguments by which each is supported. By one it is proposed that all paper-money should, like gold and silver, be coined by the state alone, in order that its issue may be properly regulated and its converti- bility secured. By the other it is maintained that the issue of paper-money should be open to all persons without restriction, like the drawing of bills of exchange, except in so far as securities may be necessary for the solvency of the issuers. In this country neither of these principles has been adopted singly, but the circulation has been founded upon the union of both. It has however been the policy of the government gradually to contract the issues of private banks, and to replace them by the notes of the Bank of England, which, for the purposes of issue, now stands in the position of the govern- ment itself.

In considering the relative merits of a system of government issues and of free competition amongst issuing bodies, there are three main questions to be considered: 1st, the profits arising from the issue of notes; 2dly, the solvent of the notes themselves; and 3dly, the effect of the future, and the present, of paper-money on the general wealth of the state. If the two first questions were the sole consideration, it would be difficult to oppose the claims of those who insist upon the right of free issue.

The first principle, that profit from principle at the bank of issue may be regarded as one of the many forms in which profits are realized by trade. It is true that the right of issuing money has ordinarily been claimed as a prerogative, and that promissory notes might be included in that category. If such a claim had been made on the first introduction of paper-money, it could undoubtedly have been supported by the analogy which paper-money bore to a coinage; and if the law had pronounced in favour of the claim, a lucrative prerogative would have been created, instead of a profitable branch of banking. But no such claim was advanced: the issue of notes has always been distinct from the coinage of money; and the state is now no more entitled to the profits arising from a paper-circulation, than to the profits of any other de- scription of business.

2. The solvency of the issuers of promissory notes is a matter which can be provided for by law. There are few who will question the necessity of some security, when money is permitted to be issued by private parties. It is indeed contended that the power of issuing money for the purpose of exchange—that it represents capital and securities, and that, in its representative character, it is circulated instead of money, upon the credit of the issuer, and upon the responsibility of those who accept it—does not necessitate the existence of a regu- lation between a promissory note and a bill of exchange. The one is.

P. C. S., No. 126.

money and discharges a debt; the other leaves a debt out- standing until the bill becomes due and is paid. Again, a note passes from hand to hand upon the sole credit of the issuer; a bill of exchange passes upon the credit of the acceptor, but also upon the credit and responsibility of each indorser. A bill is circulated amongst merchants pre- cisely as credit is given to persons of known solvency; but a promissory note, while it may be the security that is lost, if received at all, is received as money. It is obviously just, therefore, that when the state permits so important a privilege to be exercised as that of the issue of money, it should at the same time provide for the security of its effect. The issuer cannot be enforced without interfering, in some measure, with an unrestricted freedom of issue, but they are essential to the public safety, and they should on no account be neglected.

3. But the solvency of the issuers of paper-money is not the only consideration that those parties only who may happen to hold the notes of a particular bank: it does not affect the whole country. If a bank fail, its creditors suffer like the creditors of any other bankrupt firm; but the general business of the country is not disturbed by its failure. On the other hand, however, the regulation of its issues had an influence upon the entire trade of the country. However effective it may be against the insolvency of private banks—however complete the protection of the individual holders of their notes—the public interests are still in need of protection against the consequences of an ill-regulated currency.

The securities against over-issue are entirely distinct: the former may be complete; the latter may, at the same time, be inoperative. The mode of sustaining the value of paper- money on a par with the precious metals is thus explained. It is only by means of convertibility and by a refer- ence to the foreign exchanges, that the issues of paper can be adjusted to the wants of the country; and this principle is incompatible with an unrestricted issue of paper by private banks.

If no control be exercised by government or by some central body over the issues of private banks, notes will be circulated, not according to any fixed principle, nor with reference to the exchanges, but to promote the business of banking. If too many should be in circulation, the action of the foreign ex- changes cannot be brought to bear upon many independent banks with sufficient force and distinctness, and the converti- bility of all the paper-money in the country is consequently endangered. This is the danger which is sought to be averted by restrictions upon the issues of private banks, and by the gradu- al substitution of the notes of one issuing body for those of many. No interference with the business of banking would be justifiable, except for the protection of the public interests; but the evils arising from the suspension of specie payments are so great, that every practicable provision must be made to avert it. When all commercial transactions, it injures public credit, disturbs prices, and suddenly withdraws the standard of value by which all existent obligations and all specie circulating are measured. If therefore the whole body only, a limitation of its issues, as already noticed, may sustain their value; but when many independent bodies are issuing notes, during a period of inflation, the system is, of course, unable to regulate or to limit their issues, and it is almost certain that their notes will not only be greatly depreciated, but also will be liable to constant fluctuations of value.

There are some political reasons who have sacrosanct every commercial convulsion to an ill-regulated currency; while others deny its influence upon prices and upon the general arrangements of commerce. The opinions of both these vari- ations are probably extreme, and their facts somewhat exagger- rated; but the temperate view taken by Mr. S. Jones Loyd may be adopted with less hesitation. He says, 'The curren- cy, in which all transactions are adjusted, has the same reference to the healthy state of trade, which the atmosphere in which we all live has to the physical constitution of our bodies; irregularities and disorders may arise from a variety of causes, but the health and virulence of the atmosphere generally depend upon the pure, healthy, and well-regulated condition of the medium in which we exist. A well-managed currency cannot prevent the occurrence of periods of excite- ment and over-extension, nor of periods of deficiency; but it may very seriously diminish the frequency of their return, to restrain the suddenness of their outbreak, and to limit the extent of the mischief.' (Remarks on the Management of the Circu- lation, 1840.)
As yet such promissory notes only have been spoken of as payable on demand: but a few remarks may be added concerning promissory notes and bills of exchange payable at some period more or less distant. These are regarded by some as an improved and improved state of the general circulation; but the essential distinction between them and paper-money has been more than once noticed above. They do not discharge obligations, but are merely written engagements to pay at a future day. They are one of the many forms of credit, and as such are used as substitutes for money; but they cannot be considered a part of the national currency. When transferred from one hand to another they become money, as the bearer of a debt, but the payment is guaranteed by each endorser in succession. It is true that they are among the most efficient agents for economising the use of money, and that they leave the circulating medium more free for other purposes, in which payments are made in notes or specie. If this were not the case, the circulation of notes must be almost indefinitely increased in order to meet the various demand of commerce; but this economy in the use of money makes a comparatively small circulation sufficient. It is this circulation, however, of which the relative scarcity or abundance affects the prices of commodities and the foreign exchanges. The final settlement of all these circulating mediums must be in the current medium of the country. If money be dear, the acceptor exchanges more goods for it in order to meet the bill when it becomes due. If, however, it be relatively cheap, he makes a better bargain. But the bill of exchange is itself as much a money as the goods which had been originally purchased with it. Every bill of exchange when first drawn and accepted, and subsequently presents, at each commercial transaction, of which the bill is the immediate result. The number and amount of bills of exchange in circulation cannot therefore be added to the currency in order to compare the aggregate circulation with the aggregate amount of commodities; for those commodities which are exchanged by means of bills may be set off against the value of other commodities represented by the bills, while the notes and specie taken in payment may be compared with the aggregate of other transactions, added to the balances of accounts arising out of the final settlement of bills of exchange. It is undeniable that bills of exchange perform many of the functions of money, and they are regarded as a part of the circulation by some high authorities in monetary matters; but it appears to us that the balance of reason and of authority inclines to the other side and assigns to bills of exchange a distinct place as substitutes for currency instead of including them as part of the currency itself. (See the Evidence upon this point before the Committee on Banks of Issue, 1840.)

A similar question arises in reference to the monetary character of a banking department. Do they create money or not? The transfer of deposits pays debts and purchases commodities; it performs the functions of money, and so far would seem to be a part of the currency and to have an influence upon the currency. But in the former change, the whole of the deposits are money, for a large portion of them is invested by the bankers; and if every depositor were to call for his deposits at once, they could not be paid. Nor can the uninvested portion be properly called money; it is a form of credit which, like bills of exchange, economises the use of money and is a substitute for it, but is not the thing itself. It bears so close a resemblance to currency that to assign to it a distinct character is a matter of some difficulty; but still we are disposed to class all portions of banking deposits which are not actually held by the public as money; in this category fall the bills of exchange, book-debts, and transfers in amount. All these are modes of facilitating the exchange of commodities by a refined species of barter, without the intervention of any circulating medium. Each transaction is valued in the current medium of exchange, and final settlements of accounts are settled in money; but the estimated value of the transaction itself cannot be reckoned as a part of the circulation, for if it were, then commodities themselves would be money.

An ordinary case of barter would seem to offer a good illustration of the functions of all forms of credits as substitutes for money. Suppose a merchant, A, to have indigo to the value of 100,000l. that he wishes to purchase the cotton of the same value, which B is willing to give in exchange for the indigo. The transfer is made at once between them: the transaction is complete without the passing of a shilling, for the indigo performs the functions of money. But can the indigo on that account be reckoned as a part of the circulating medium? Suppose again, that these merchants, at the time of the transfer, each drew a bill for 1000l. upon the other at three months, which each accepted. These bills would represent the whole of the exchange in the clearing of the cotton; but no money would pass between them until these bills became due, than if no part of their bargain had been committed to paper. When the bills became due, each would be indebted to the other exactly to the extent of the sum on the face of the other; or each might transfer a portion of his bank-deposits to the other. In the case first supposed, no money would pass, but one commodity would be taken as an equivalent for another, and for that purpose the cotton and indigo might be accepted as an equivalent for the goods without the intervention of a money payment: and this credit would afterwards be exchanged for another form of credit—a bank-deposit. In neither case, as it would seem, does the transaction involve the use of any portion of the circulating medium, nor call any new description of currency into existence.

It is of the utmost importance to form a clear opinion as to the distinction between various forms of credit and the circulating medium of a country; for if they be confounded one with another, all the established theories of currency are put into confusion. All hopes of regulating and controlling the circulation must be in vain, and the variety and magnitude of the consequences of a bad system would be such as to defy the operations of the government, or of a bank, by means of paper issues, which would form only an insipid substitute for an adequate currency; and free trade in banking and free trade in the circulation of money might be recognised as the only reasonable principle for supplying commerce with a circulating medium.

We have stated the two main principles involved in the consideration of the character and functions of money. In treating of a subject which has been so fruitful of controversy, we have been obliged to touch lightly upon many points which to deep students of the 'currency question' may seem to have deserved more consideration. To examine them fully would add volumes to the many which have already been published upon that subject; and frequent allusions to the opinions of others; besides ourselves, have given a counter-

...
MONNOYER, JEAN BAPTISTE, a very celebrated fruit and flower painter, was born at Lille, in 1685. He was educated as an historical painter at Antwerp, but he afterwards adopted the plant, and went to Paris, where he was noticed and employed by Le Brun, and in 1655 was elected a member of the French Academy of Painting. He was employed by Le Brun in the decoration of the palace of Versailles, and in an assortment of flowers and other similar pieces. It was owing to the beauty of these works that he was invited, about 1689, to London by the Duke of Montague, then English ambassador at Paris, to decorate Montague House (the present British Museum), a siting place of flowers and other similar pieces. The free and beautiful flower decorations of this palace, which is now pulled down, must still be fresh in the recollections of many who have been in many other nobleman's houses in London and at other places; at Burlington House, at Lord Carlisle's, at Hampton Court, and at the Duke of St. Albans' at Windsor. One of his most remarkable works is a looking-glass painted in Kensington Palace for Queen Mary, which was purchased for a very high price from seeing him paint, that he spent nearly all the time that he was at work in watching him. There are fourteen flower-pieces by Monnoyer, or Baptiste as he is now called, all made in England, in the apartment named George II.'s private chamber, at Hampton Court; they are however dirty and badly hung. Monnoyer was commonly styled the 'flower-painter' in England in his own lifetime. He paid a few visits to Paris after his first visit in London, but his permanent abode was in London, where he died in 1699, and was buried in St. James's. The French offended him by allowing his son-in-law, who was a painter and living at Paris, to be his partner in the business of the flower-painting business in London. Monnoyer's style, though not so far as minute or highly finished as that of Van Huysem, is infinitely more free and more brilliant, equally true and more effective; this is the result of his colouring, and light and shade, and touch, are all equally excellent and faultless: his works in their perfect condition must have rivalled nature herself. The brilliance of his colouring is extraordinary. He was particularly skilled at grouping roses, poppies, tulips, and a few white flowers together in a blade vase, and there are several etchings of such groups by his own hand: the vases are placed on pedestals or tables. His best works and in this country. The prints after his works amount to over 80, and make a good folio volume: his own etchings are marked J. Baptiste, sceps., whereas probably his now common name of Baptiste. His son Antoine Monnoyer, likewise a good flower-painter, was called the younger Baptiste in England. There is a portrait of Monnoyer engraved by White from a picture by Sir Godfrey Kneller.

MONOTROPA (from μονός, one, and ρίζα, a turn), a genus of plants belonging to the natural order Ericaceae and the family Monotropaceae. The species Monotropa uniflora consists of 4-6 petals each, with a hooded nectariforous base; 8-10 stamens with kidney-shaped 1-stellate anthers; a pelted stigma; the capsule 5-stellate, 5-valved, many-seeded. The species of this genus are singular, occurring in single parts, growing in the roots of trees, and destitute of the green and yellow characters which characterize the other forms of vegetation. The flowers of yellow Bird's-Nest, has the flowers in a drooping cluster, lateral ones with 8 stamens, the terminal ones with 10 stamens, the flower erect, the bracts and flowers glabrous externally. The stem of this plant attains a height of 6 or 8 inches, and is silvery-white, the leaves terminating in a short cluster, dingy yellow, at length turning nearly black. The flowers with large scaly bracts. It is native of Great Britain. This, with the other species of Monotropa, appears to have been supposed by Linnaeus to be parasitical upon them; recent researches have, however, led to the conclusion that in the case of this species such an opinion is erroneous. Mr. Rylands, in a paper published in 1861, has stated that the species Monotropa uniflora possesses masses of a fibrous substance, which adhere to their fibres and the roots of the plant near which they grow, so closely that they are supposed to be portions of the roots of the Monotropa. On examining this fibrous substance with care, Mr. Rylands found that in all cases it consisted of a species of hyssodoid fungus which had been developed upon the roots of the Monotropa, having no organic connection with the plant. On the appearance of Mycosphaera, varicollic in different specimens, and were found to belong to hitherto undescribed forms of Cryptocaps. There can be little doubt that the other species of Monotropa are of the same nature as Hypopygium, and that these old names have referred the species here described, and two others, to a genus called Hypopygium. This includes the European species, whilst the old genus, Monotropa, embraces two North American species, namely M. californica and M. uttifera. The last species have not the musky semi-fragrant odour of those belonging to the genus Hypopygium. (Don, Gardiner's Dictionary; Physiologist, vol. i.; Bayntting, British Flora.)

MONTAGUE, GEORGE, was descended from an ancient family residing at Lackham, in the central part of Wiltshire, where he had an estate. He was distinguished for his love of natural history, and was one of the early members of the Linnean Society of London. In 1802 he published an 'Ornithological Dictionary, or Alphabetical Synopsis of British Birds,' 3 vols. 8vo. This work exhibited much research as well as an extensive knowledge of the department of natural history to which it was devoted, and may be consulted with advantage at the present day by the ornithological student. In 1803 he produced his 'Testacum Britannicum; or a Natural History of British Shells,' 2 vols. 8vo, containing several plates and descriptions of new species. Besides these two great works he published several papers in the Transactions of the Linnean Society. Of these the following are the principal—

4. On the larger and lesser Species of Horse-shoe Bats, proving them to be distinct, with a Description of Vespertilio Barbastelliates taken in the South of Devonshire. Vol. ix. 1805.
6. Of several New or Rare Animals, principally Marine, discovered on the South Coast of Devonshire. Vol. xi. 1811.
7. Of some New and Rare British Marine Shells and Animals.—Ib. During the latter part of his life Mr. Montague lived at Knowle, near Kingsbridge, in Devonshire, where he died in 1815. (Biographical Dictionary of Living Authors; Watts's Bibliotheca Britannica.)

MONTALEGRE, MARC-BENE, MARQUIS DE, a distinguished military engineer of the eighteenth century, was born July 16, 1714, at Angouleme. He was descended from an ancient and noble family; and, having received an education in which both literature and science were judiciously conjoined, he entered the army at eighteen years of age. In the course of his first campaign (1733), he was present at the siege of Basle, and in the following year joined de Prasle, engaged him. It was afterwards, the consideration which he held by the military art. He was admitted a member of the Académie des Sciences in 1747; and he wrote several memoirs of improvement in the volumes published by that body. About the same time he established a foundry at Perigord for the purpose of casting heavy ordnance, which was then much wanted for the French navy. During the Seven Years' War Montalegre, attached, as an agent for the French government, to the staff of the Swedish and Russian armies; and he appears to have been consulted by the allied generals respecting the arrangements of the plans for the different campaigns. In 1774 he
published a small work entitled 'Correspondance pendant la Guerre de 1757,' which contains much interesting matter relating to that war. In 1778 he was appointed to construct a fort for the purpose of securing the Darte of Aix against the English fleet; and this fort, which was built entirely of wood, is said to have borne, without experiencing any damage, the shock occasioned by the simultaneous firing of all the artillery which had been directed against it; it has been made in order to disprove the assertion of several engineers that the fort would fall in ruins by the fire of its own guns.

Montalembert published, in 1756, a small work in 4to, entitled 'La Fortification Perpendiculaire ou l'Art Defensif superieur a l'Osmale,' which was published at Paris in eleven quarto volumes (1776 to 1796). In the first volume, having shown the defects of the bastioned fortifications which are constructed according to the principles of Vauban, he proposes to suppress the flanks of the bastions, continuing the faces of those works till they meet in the middle of each front of fortification, and, at the same time, a casemated work like a small ravelin. The advantage to be gained by this project is, that it saves the expense of the construction; and, after proposing some other modifications of the existing fortifications, Montalembert dwells at length on a system which gives its name to the treatise. [FORTIFICATION, P. C.] The perspective drawing of the fortifications, the branches of which form right angles with one another at the re-entering parts, and three of these are defended by a powerful fire of artillery, which, being placed in casemates, is not liable to be destroyed by the enemy; while spacious terre-pleins at the foot of each rampart afford rooms for the troops of the garrison to engage the besiegers with forces superior to any which can be brought against them.

In a second volume, after giving an interesting account of the war in 1741, in which the importance of fortified positions is pointed out, he describes the construction of redoubts or small forts. In the third volume there is a project for the construction of a simple fortification, consisting of a creased wall covered by a rampart on which are constructed casemated traverses: this is proposed as a good kind of defensive work for sea-ports; and it is said that some of the forts which defended Cherbourg were executed on this principle. The fourth volume contains an abridged history of the reign of Louis XIV., together with sundry projects relating to the formation of lines of intrenchments for the defence of the coast. In the fifth volume, he remarks the state of the batteries for the defence of seacoasts; and the sixth and seventh volumes are occupied with refutations of the objections which had been made to his system, and contains plans of the forts at Cherboue and on the Isle of Aix. The ninth volume, which is particularly entitled 'L'Art Defensif superieur a l'Osmale,' contains sundry projects for circular redoubts and for the construction of redoubts.

In the tenth and last, he contains memoirs relating to fortification and artillery. The leading principle on which the projects of this engineer are founded, is that a fortified post should contain an abundance of casemates for the security of troops and artillery: Montalembert considers that these alone will enable a small number of men to resist with success the attack of a numerous army, and that a few guns so protected are capable of dismantling all that an enemy can place behind parapets made merely of earth. His projects were severely criticised during his life; but, though some parts of his constructions are open to objections, the principles are unexceptionable; and it is important to observe that many of his ideas have been adopted by the Prussian and Austrian engineers in the works recently constructed for the defence of Western Germany.

In 1770 Montalembert married a lady who was distinguished as a performer on the stage, and who wrote a novel entitled 'Elise Dumesnil,' which was printed in London in 1798. It is said that Montalembert composed for the theatre some small pieces which had a certain success, and that the attachment to which he is proved to have been indebted for the fact that his biographer, Lalande, had, in his possession a number of his songs and tales in verse which are said to have been characterized by grace, elegance, and imagination. In publishing his great work, and in making his experiences for the improvement of the military art, he seems to have incurred expenses which injured his fortune. He had given up to the government his founreder at Perigord, and his application for the reversion of the same was rejected, for which he claimed that the 3000 francs which he received as an equivalent were fruitless; he was even deprived of a pension which he enjoyed for the loss of an eye in the service of the country. About the year 1790 he came to London; but, after some years of some success, he was forced to leave his wife in this country. It is said that, in order to save some of his property, he joined the revolutionary party; and it is painful to record that he entered so far into the prevailing spurious ideas of the time.

Monten, Dietrich, an eminent German battle painter, was born at Düsseldorf in 1790. He showed from his earliest youth a great love for accounts of wars and battles; and he was ever a friend to the English painter, Hogarth, from whom he used to sketch the most striking scenes of arms. In order that he might have some practical knowledge in military matters he enlisted into the Prussian army as a volunteer in 1818, and served accordingly for twelve months. At the expiration of his term of military service, he entered the Academy of Arts of Düsseldorf, and after studying two years in that institution he removed to Munich, in order that he might benefit himself by the study of the works of Tieck, Herbrand, and rivals Horace Vernet as a battle painter, and is still resident in Munich.

Monten was not long in attracting the attention of Cornelius, then the Coponcussa of the painters of Munich, and the notice of the present king of Bavaria, Ludwig I. He was intrusted by Coradelli, in 1827, with the execution of three of the frescoes of the arcade of the Hofgarten—the storming of the Dutch and the night attack, and the battle of Saarbrück, 1815, for the Hall of Victory (Siegesaal) in the state apartments of the new palace; and for the same patron of the arts, the departure of the Foles from their fatherland, and the meeting of the Garatowia with the Turks. These were painted for the Tyrolean hall in the hunting lodge of Prince Adolphus in the battle of Lützen, in the King of Hanover's collection; in 1838, by George I. in the battle of Neurwinden; and in 1830, by the great camp in 1838 at Augsburg, for the Emperor Nicholas, at which the emperor was present. He depicted besides these principal works many smaller pieces, which are all conspicuous for extraordinary spirit in the incidents and in the execution, and display much fine drawing and fine colouring, though in many parts too sketchy and undefined; he wanted the necessary patience for elaborate moulding and uniform finish. But when the exact degree of this technical excellence is missed, its absence is more agreeable than its excess; and all Monten's works have a very agreeable effect: their greatest defect is an occasional extravagance of action. His horses are always very spirited. He died after a short but severe illness, in December, 1844, in the prime of life, being in his forty-fifth year; but his memory is universally regretted by all who knew him. Several of his works have been lithographed by Bodmer, Hamstädl, and others.
verses; but the very few events of his life which are exactly known fall within the reign of King James VI. of Scotland. He is described as having been a captain, probably in the guard of Morton the regent. King James quotes some of his poems in a work of his own, published in 1592; and he owned the manuscript of a hundred or more, which led him into a troublesome law-suit on his return from a continental tour, begun in 1586. He appears to have died between 1610 and 1614. It is thought that he wrote and published his principal work, an allegorical poem, called The Cherry and the Sloe (or Sloe). This poem is still popular in Scotland, and has been very frequently reprinted in recent years. It is a romance, and both the style and subject of the poems are both lively in fancy and pleasing in versification. In 1582 there appeared at Edinburgh a neat edition of all his poems, edited by Mr. Laing, with a biographical preface by Mr. Irvine.

MONTIA, a genus of plants named in honour of Dr. Joseph Monti, professor of botany and prefect of the medical garden at Bologna. He paid much attention to the scientific arrangement of the Gramineae and Cyperaceae. He published also a catalogue of the plants in the botanic garden at Bologna, in which he described several new species. The following are the principal works which he published:—1, *Catulli Stirpium agri Bononiensis, Gramineae et Cyperaceae deponenda complectens*, Bononia, 1719, 4to. 2, *Indices Horli Bononiensis ad Usum Demonstrationum quae in Horto Bononiensi quadrantis habentur*, Bononia, 1724, 4to. 3, *Descriptio curiae, capítulo, et arborum Regis Hortus Portulacaeae*, and has a persistent caustic of 2 sepals; a corolla 5-parted with 3 segments smaller than the others, with the tube split to the base in front; 3 stamens inserted in the throat and opposite to the sepals. The flowers are white or pink, the style very short; the stigmas 3, downy; the capsule of 1 cell with 3 valves and 3 seeds. There is but one species of this genus, *M. fontana*, which is native of Great Britain. It is also found in North America and long-petalled, white, and ditches; and is commonly known by the name of waterhickweed. It closely resembles the species of the genus Claytonia (Washington, *Manual of British Botany*).

MONTORSOLI, FRA GIOVANNI ANGELO, a celebrated Italian sculptor, was born in 1507, or about the beginning of the sixteenth century, at Montorsoli near Florence, on the road to Bologna, a villa belonging to his father Michele d'Angelo da Poggibonzi. He was first instructed by Andrea da Firenze, with whom he lived three years. After the death of his father he found employment at Rome, at Perugia, and at Volterra, where he assisted in making the monument to Raffaello Maffei. He was next employed by Michelangelo in the church of San Lorenzo at Florence, and gained the admiration of the greatest artists in the city. In 1547 Montorsoli had a special dispositive to Rome as it appeared to him to the only life in which peace was to be obtained; but after trying in vain several convents, he fixed, in 1550, upon the church of San Lucina, and began to work as a friar of the order of Servi della Numizita. Shortly after he had taken up his abode in this convent, he was called to Rome by Clement VII. to restore several ancient monuments, much to the dissatisfaction of his brothers of the Numizita: he had been recommended to the pope by Michelangelo. Montorsoli restored the Laocoön, to which he made the right arm, and he made the left arm of the Apollo, and executed other restorations. When these and a statue of the pope were finished, he returned to Florence with Michelangelo to complete the statues and other sculptures of the sacristy and library of San Lorenzo, of which his best is San Cosimo. After the death of Clement, Montorsoli again joined Michelangelo at Rome and assisted him in the works of the monument of Julius II.; but while engaged on this work he was invited by Cardinal Tornone, and advised by Michelangelo, to go to Genoa and become a commissary in charge of making him to make four great statues, but owing to difficulties with the treasury and servants of the court in France's absence, Montorsoli left Paris and returned to Florence without executing his commission. He then went to Naples, and there constructed the tomb of Jacopo Sannazzaro. He next finished at Genoa the statue of Andrea Doria which was commenced by Domenico, and was now finished by him. At Florence, he finished the church of San Matteo there with many works. Upon the completion of these works he returned to Michelangelo at Rome, but departed again soon afterwards, in 1547, for Messina, where he was employed to make a grand fountain for the place in front of the cathedral. The principal basin is thirty-four palms in diameter, and is ornamented on its twenty irregular sides with twenty bassi-relievi illustrating the various ancient fables connected with the watery element: it has besides the usual usual spout in the centre of which is contrived for jetting the water: the whole fountain is crowned by a figure of Orion with the arms of Messina engraved upon his shield. The second basin is forty feet in diameter, and the great work induced the Messinese to commission Montorsoli to erect another fountain in the front of the Dogana (Custom-house) close to the sea. He designed also at Messina the church of San Lorenzo, a large and beautiful edifice containing other admirable works in architecture and in sculpture. But in 1557 by a decree of Pope Paul IV., all religious persons, or all who had taken holy orders and were living at large in the world without respect to their religious character, were ordered to return to their convents and resume their religious habits; and Montorsoli was accordingly obliged to leave many works unfinished, which he intrusted to his pupil Martino, and he returned to his convent at Florence. He was however shortly afterwards called to Bologna to construct there the high altar of the church of his own order dei Servi, which he completed with great magnificence in twenty-eight months. He returned to Florence in 1561, and being rich he built a sepulchre for artists in the chapter-house of the convent of the Numizita, with the requisite endowment for regular masses at appointed times, and gave the whole sepulchre, then the most costly in Florence, to the convent of the Holy Luke, or company of painters, &c., which upon the completion of the sepulchre, was at a solemn feast celebrated by forty-eight of the principal artists of Florence, re-established by the consent and authority of the Pope Julius II. He died on the 17th of May, 1566, and was buried with the convent of the Church of the Holy Luke. His body was afterwards removed to the church of San Lorenzo at Florence. He was a man of fine taste and great erudition, possessed of a large library of useful books and pamphlets.

MOORELLI, COSIMO, an Italian architect of considerable note among those of the last century, was born at Imola in 1730. He was the son of Domenico Morelli (an architect also), and studied under his father. He was placed in several works of merit at Imola. It was Cosimo's good fortune to obtain powerful patronage at the very outset of his professional career,—first that of Gian-Carlo Nandi, bishop of
Of Imola, for whom he made designs for rebuilding the cathedral of that city, and through him, that of his nephew Giovanni Antonio Braschi, who was elevated to the papal throne in 1775 under the name of Pius VI, who inevitably appointed him city-architect at Cesena (the pope's native town), and among various other commissions concerned with the design for the new building of Peter's. If that and some other projects were not realized, the designs themselves obtained universal though transitory admiration. No art is more subject to blight than architecture, perhaps of which the fashion is often rejected as quickly as it is adopted by him, namely, the cathedral of Imola, the metropolitan church at Fermo, the duomo at Macerata, and the conventual church at Fossombrone, St. Petronio at Castel Bolognese, a church at Barbianum, that of the nuns of St. Chiara at Imola, and St. Maria in regola in the same city, and another church at Lugo, also some alterations in the metropolitan church at Ravenna. It happens, too, rather singularly, that Morelli was almost as much employed in theatrical as in ecclesiastical architecture. The buildings of this class erected by him are—the theatre of Imola (destroyed by fire a few years afterwards, but preserved in the volume of engravings of the buildings of Ferrato, Ferrao, Jeonini; also, that of Ferrara, which is confidently claimed for him by some, although Foschin was likewise in some manner or other employed upon it. [Foschin, P. C. S.]) Besides the above works, he has been engaged at Hangaroa, at Genoa, at Pisa, at Fiume, the Berio at Naples, and the Cappel at Bologna; the façade of the Ridotto at Cesena, and the Hospital at Imola, the façade of the Palazzo Publico, and the Palazzo Vecchio. He would probably have done more, had occasion not always been wanting. The uncertain state of things in Italy for architecture towards the close of his life. He died, after a severe paralytic attack, in February, 1775.

(T. Papotti, in Tipaldino's Biografia.)

MORELLI, GiaC ouMO, one of the most distinguished librarians of modern times, was born at Venice on the 14th of April, 1746. He was the son of poor parents, who were unable to give him a liberal education. It was against his will that he resolved to enter the church, although in all other respects he always showed the greatest deference to their wishes. He afterwards supplied the deficiencies of his education by private study; and the knowledge which he thus acquired was more substantial and extensive than that of any of his Italian contemporaries, though it was not till late in life that he became acquainted with the Greek and French languages; through his own studies he became a good Latin scholar, well acquainted with the library of the family of the Zaniani, and his unsubmitting perseverance attracted the attention of the librarian de Rubia, who became his secretary and a friend. After having traveled through the greater part of the country in Italy with the avowed object of acquiring knowledge, he led him to examine the other libraries of his native city to which he could gain access. His love of independence induced him to refuse several very advantageous offers that were made to him both by the church and by wealthy collectors of books at Venice, and he continued to live as a simple Abbé. He formed however an intimate friendship with the patrician Farsetti, of whose rich collection of MSS., he published a catalogue, under the title of 'Biblioteca Manoscritta del Bar T. G. Farsetti,' Venice, 1771-80, 2 vols. 12mo. While this work was in course of publication he also wrote 'Considerazioni storiche della Biblioteca di S. Marco,' Venice, 1774, in which he discussed and solved a great many questions connected with the history of literature. He then prepared a similar work on the history of the MSS. of Venice, which he published in 1783. He also accompanied his friend Farsetti; but the materials which he collected for that purpose were unfortunately left in the hands of Colle, the historiographer of that institution, through whose care they were lost.

The next catalogue of the MSS. of the library of the Narni family; and somewhat later a catalogue of the MSS. of Italian works contained in the same library. The last two publications are of an honourable place among the eminent bibliographers of modern times; but he acquired a still greater reputation as librarian of the library of St. Mark, an office which he received in 1778, and which he held until his death, which happened on the 6th of May, 1819. He devoted himself with the greatest zeal to the completion and arrangement of that famous library; but during the French rule in Italy he was, together with his projects for the building of a new library from its venerable antiquated building to a new one, the splendid and convenience of which however caused him in some measure for the loss of the former building. In 1795 he discovered a manuscript of Dion Cassius, which he published at Bologna, together with several new readings of other books of the same historian. This little work was afterwards (in 1800) republished at Paris, under the title of 'Dion Cassius,' of which only one volume was published. Although Morelli's work exhibits his extensive knowledge and his critical acumen in the strongest light, its 'Biblioteca Manuscritta, Græcorum et Latinæ,' of which only one volume was published, was not so successful, though it contains many valuable materials for several more volumes. His last production was 'Epistolæ Septem variae Erodutianæ,' Padua, 1819. Abbé Morelli is acknowledged by all who have occasion to visit the library of St. Mark during the time that he was at the head of it, to have been the most amiable, kind, and obliging person, and his vast learning was equalled only by his extraordinary modesty. After his death there appeared, 'Oeuvres inédites du M. de l'Abbé Morelli,' by his son, Monumenti dell'Istituto di Antichità Scrittori, Venice, 1820, 3 vols. 8vo.

(Bettio, Orazione recitata nelle solenni Eseguene nella Chiesa Patriarciale di Venezia, Venice, 1819.)
Filippo must have made a visit with his wife to Florence some time after his marriage, and before the birth of Raphael, as Florence was a popular resort of artists and a centre of art and the prints of the celebrated plate engraver were sold as early as his twelfth year. But his first engravings of consequence were seven plates from the masks of the carnival of 1778, the Pilgrimage of the Green Lion, and the Celebration of the Monstrous Fruit. The engraver was then but a youth of twenty, that his father deemed it right that he should have the benefit of the best instruction that could be procured, and sent him accordingly to the celebrated Volpato at Padua, to be instructed in engraving, as a whole master. He never entered the Church and Mary Magdalen in the Garden, to copy. He engraved also about this time Gavin Hamilton’s allegoric figure of Painting, for the brothers Hackert. In 1781 he engraved Raphael’s allegoric figures of Poetry and Theology, from the Vatican. In the same year he married Volpato’s only daughter Domenica; and assisted Volpato on his plate of the Panamaus of Raphael, or the historical illustration of Poetry, in the Stanz of the Vatican. In 1787 he engraved the Aurora, painted in fresco by Guido for the garden-house of the Palazzo Rospigliosi; but this, though one of his principal works, is not one of his best. Though some of its parts are better, the Hours around the chariot of the Sun are less graceful and less buoyant than those in the print by Fry, executed long before it. The extremities, especially the hands, are both badly drawn, but those of Morghen’s print are inferior to those in the print by the former. In 1788 Morghen went to Padua, and is said to have been damaged. The impressions without the words ‘In Aedibus Rospigliosii’, and those taken before the retouches, are much more valuable than any of those taken afterwards. In 1790 Morghen visited Naples, and engraved a portrait of his father. The Neapolitan court wished to persuade him to reside at Naples in 1794, and offered him the post of a Salary of 600 scudi and free apartments for the engraver, under the condition that he should keep a public school; with the privilege of engraving what he might choose, and his prints remaining his own property.

The first print engraved by him in Florence was the Madonna della Seggiola. In 1796 he commenced the celebrated Madonna del Sacco, after Andrea del Sarto, and Raphael’s Transfiguration; but his time was much taken up by portrait commissions from the royal family of Florence. The first picture is in Florence; the second he engraved from a drawing by Tofanelli: he had commenced one from a copy by A. del Etra; but upon comparing this with the original he found important elements of gesture which had already done. This practice of engraving from copies and publishing the works produced as engraved from the original pictures, may be a custom with engravers, but it is a practice which is only in Latin art, and is not in the usual practice within the reach of the engraver, or unless the source be acknowledged upon the print. An engraver may commence his print from the print of another man if he has compared the copy with the original and found it to be exact; but an acknowledgment of the assisted availing is imperative in point of honour. A proof which is sold as a faithful copy of a certain work of art, and is only the copy of a copy, without reference to the original is a forgery. Jordan, the Russian engraver, who has just completed a very large and excellent engraving of the Transfiguration, was actually engaged thirteen months in the Vatican making his chalk drawing from the picture of Raphael on which his picture is based. The artist was pronounced by all who saw it as exact a copy as could be made. All engravers cannot do this, but they can all ascertain whether the drawings they work from are approved copies or not.

Morghen’s Transfiguration was not completed until 1812, when it appeared with a dedication to Napoleon, and the emperor invited the engraver to Paris, and honoured him with various privileges. In 1870 he made the lithography etchings of Hollande and England, which stayed for a considerable time in London, where he enjoyed the society, among others, of Boyle, Isaac Vossius, and Oldenburg, the secretary of the Royal Society. On the 2nd of October, 1871, he died, at Kiel, mourned by his widow, Cäsar de Déguing, senator of Lilbeck. She died in 1887, after having brought him four sons; of whom the second,
George Marquand, and the fourth, Eric George, died young; the first, Caspar Daniel, and the third, Frederic, survived their father.

In 1658 Morhof succeeded to the professorship of history; and in 1680 he was appointed librarian to the university. The latter charge to so devoted a reader was peculiarly gratifying. From the time of the loss of his wife, however, his health began to decline. In 1699 he was much weakened by a severe illness; and when he had partially recovered, in the spring of the following year he undertook an ill-advised journey to the mineral waters of Pyrmont, from which he never returned: he had got back as far as Lübeck, and there breathed his last, on the 30th of July, 1691, in the fifty-third year of his age.

Morhof was a very voluminous author. The account of his writings, published and unpublished, fills nearly fifty pages of the memoir by his friend Moller. His first production was a collection of twenty Latin poems, published together in 1657. This was followed by an academical dissertation entitled 'Diatribe de Morbis et eorum Remedia Juridica,' in 1658; and afterwards, among other works, by an octavo volume entitled 'Epigrammatum et Jocorum Centuria Prima,' in 1659; 'Diatribe Philologica de Novo Anno ejusque Ritibus,' in 1663; a curious defence of the miraculous powers claimed by the kings of England and France in the cure of the king's-evil, under the title of 'Principes Medicus,' in 1665; a volume of 'Miscellanea Poetica,' in 1666; another entitled 'Venerum, sive Epithalamionum, Liber,' in 1667; another entitled 'Funebres,' with an account of the funerals of lettuce at various times; a translation into Latin of several of Boyle's tracts, in 1671; 'Disputatio de Sole Igneo Academica,' in 1672; 'Epistola de Transmutatione Metallorum,' in 1673. The last-mentioned work is evidence that he believed in the philosopher's stone; in 1682, an octavo volume, in German, on the history of the German language and poetry ('Unterricht v...')...dichtes'); in 1684, 'Liber de Patavinitise Liviana'; in 1686, 'Otorium Divinorum, seu Carminum Sacrorum, Liber'; and the first and second books of his 'Polyhistor,' in 1688. After his death, and amongst other works of his, are published two volumes of 'Moralis Morhofi CVIII.' Quaestiones Chymicae, ex variis Autoribus Chymicis collectae; in 1697, 'Morfophi Opera Poetica Latina omnia'; in 1698, 'Morfophi Orationes et Prologiunna'; in 1699, 'Morfophi Dissertationes Academicae et Epistolicae.' For the works which he left in manuscript, mostly in an unfinished state, and which have never been printed, we must refer to the same pages of his biographer. They are far too numerous to be noticed here. So great a quantity of literary production in so short a life sufficiently attests Morhof's diligence and facility. His judgment, however, appears to have been hardly in proportion to his acquisitions; and even his learning was not remarkable for the high extent for its depth. Of all the mass of authorship to which his name is attached, his 'Polyhistor' is, we believe, the only portion that is esteemed by any esteem.

The full titles of his works are as follows: 'Polyhistor Literarius, Philosophicus, et Practicus. Of the Polyhistor Literarius,' intended to form the first volume, Two Books, as already mentioned, were published by the author himself in 1688. They were brought out in 4to, at Lübeck. The First is entitled 'Bibliothecarius'; the Second, 'Methodicus.' As reprinted in the last edition of the work they make together 688 pages. A Third Book, entitled 'Paraphrases,' was printed from Morhof's manuscript at Lübeck in 1692, with a re-impression of the two preceding Books. It extends to 160 pages. The remainder of the first volume, consisting of Book iv., entitled 'Geographia,' pp. 104; Book v., entitled 'Critica,' pp. 88; Book vi., entitled 'Oratorium,' pp. 82; and Book vii., entitled 'Poetica,' pp. 72, was compiled from notes of Morhof's lectures, by Moller and John Frickius, professor of theology in Bremen, and published as 'Morfophi Literarius,' in Five Books; and the 'Polyhistor Practicus,' in Seven Books; and published the completed work in two vols. 4to. In 1704. A new edition of the whole work was published in 1731. In his lifetime, a fourth edition and another edition in 4to., by the same editor, in 1747. All the editions have been published at Lübeck. With the ample indexes which Fabricius has appended (though the plan of notation is rather complicated), and with the corrections, additions and additions which it has received from his extensive and accurate learning, the 'Polyhistor' is still a useful survey of universal literature down to the middle of the last century.

As in almost all such works, however, some subjects which happened to be favourites with the author or his editors, are treated at disproportionate length, while others of greater real importance are too summarily dismissed.

Van Antwerp, or Sze Ander Wenzel, was born at Utrecht, about the year 1526, and was the pupil of Joan Schoorel. He obtained, while still young, a great reputation in Rome, especially as a portrait painter, and when the Emperor Charles V. went to Spain he accompanied him to Lisbon, to paint the future bride of his son Philip, the cardinal selected More. He was introduced to the Emperor, at Madrid, in 1553, painted Philip's portrait there, and, at the same time, painted that of Isabella, King John III., and the emperor's youngest sister, Queen Catherine of Portugal; for which he received 600 ducats and a very valuable gold chain as a present. Van Mander says that the usual price for such a portrait was 100 ducats, which at that time was a very large sum.

After a short interval, in 1554, More was sent to paint another bride of Philip's, Queen Mary of England: for this picture he was also richly rewarded, says Van Mander, and had a salary of 100l. per annum settled upon him, as painter to the King and Queen (Walpole says 100l. per quarter). More remained in England during the reign of Queen Mary, by whom he was probably knighted, and he painted several portraits of her and many of the English nobility of the time, some of which are at Hampton Court, and many others are still in the private collections of the descendants of the families. Some years after this, it is said, he went to Spain, and was more much inferior to Holbein. After the death of Mary, in 1558, More rejoined Philip in Spain, and appears to have lived on such terms of familiarity with the king, that, upon an occasion he painted a picture, Barbossa, on horseback with open hand on the shoulder, the painter ventured to return a blow with his malahitse, but he soon repented of his familiarity, and was heartily glad to escape with temporary banishment. Philip, however, sent to release him, and the king's messenger overtook More on his way, but the painter excused himself, not daring to trust himself again within Philip's power. Philip wrote to him in the Netherlands, and More, in 1564, paid a visit to Utrecht. More had entered the service of the Duke of Alva, who sent for him from Utrecht, and he was appointed by the duke receiver-general of the revenues of West Flanders, an appointment, says Van Mander, which so elated him, that he made a bonfire of all his painting materials at Utrecht, and made presents to all his friends. Some suppose from this that he gave up painting; but so far from this, he was constantly painting, especially portraits of women, for the duke, at Brussels, whose high position enabled him to reward the painter with a public office for private services. The whole of More's family was also richly provided for, by Philip, or by the duke.

More died at Antwerp, in 1561, aged fifty-six, while engaged on a picture of the Circumcision, for the church of Notre Dame there, and it was left unfinished. More painted chiefly portraits; and it is said, were few figures which he was not able to fill, but that he painted in the prevailing dry style of that time in the Netherlands, and with its hard positive colouring. Yet he made a good copy for Philip, of Titian's Danae, which is now at Madrid. There is much confusion about the dates of More's birth and death, some placing his birth in 1512; the above, however, is the account in the second edition of Van Mander, where it is fully explained in a note. More's portrait is in the Florentine gallery of painters' portraits.

(Van Mander, Het Leven der Schilders, &c., 1764.)

MORPFETH, a municipal and parliamentary borough in the township and parish of Morpeth, in the western division of Morpeth ward, in the county of Northumberland; 820
MOR

329

yards by 58, is occupied as a nursery-ground. The town-
hall, a building by Sir John Vanburgh, was used as a ses-
sions-house until the erection of the present gaol.
There are a Roman Catholic chapel and meeting-houses for Pres-
byterianists, Independents, and Quakers. Among the most
famous literary worthies who have lived in Morpeth is
Horsey, the antiquary, author of the 'Britannia Romana,'
who was minister of the Presbyterian congregation from 1729 till
his death in 1791, at the age of forty-six. The truth of Morpeth
is not of much authority, but the town is noted for its
four limestone quarries, which supply stone for live stock on Wednesday: the weekly sale of oxen is
200; of sheep and lambs, 2500. There are a dispensary,
a savings-bank, incorporated in 1780, a Mechanics and
Scientific Institution. Races are held every year at the
last week in September, on a course on Cottong-wood, north of
the town. The race-course is about a mile and a quarter in
circuit.

Morpeth is a borough by prescription. Under the Mun-
icipal Corporations' Reform Act, it has 4 aldermen and 12
councillors, and is not to have a commission of the peace
except on petition and grant. The borough first sent mem-
bers to parliament in 1553. It returned two down to the
time of the Reform Act, when it was reduced to one. By
the Boundary Act its limits for parliamentary purposes were
enlarged, and the county boundaries to the extent already
already described. The number of registered electors was
in 1835-6, 354; in 1859-60, 363; in 1842-3, 428, namely
142 freemen and 286 ten-pound householders. Morpeth is a
rolling-station for the northern division of the county of
Northumberland.

The town of Morpeth is not noticed in history till the
reign of John (a.d. 1199), who granted a charter for a fair
and market; but it is possible that John a.d. 1066 had
the barons. In the civil war of Charles I., Morpeth
Castle was occupied by a body of the Scottish Covenanters,
from whom it was taken in 1644 by the Marquis of Montrose.
The late Dr. Morpeth, one of the eminently distinguished
natives of Morpeth. The town gives the title of Viscount
to the Earl of Carlisle, and by courtesy to his eldest son.

The living of Morpeth is a rectory, with the perpetual
curacy of Upleatham, one of the several manors which
constitute the archdeaconry of Lindisfarne, in the diocese of
Durham: the annual value of the benefice is 161l. with a glebe-house.

There were in the borough in 1833 thirteen day-schools
with 448 to 456 scholars, viz. 269 to 270 boys and 188 girls;
giving less than one-eighth of the population under daily
instruction. Of the day-schools one, with 43 boys, was
a free grammar-school founded and endowed by Edward VI.: the
building having been erected at the expense of the
earliest and the wealthiest of the town.

(Parliamentary Papers; Hodgson, 'History of Northum-
berland.')

Morton, Thomas, was born in 1764, in the county of
Durham. His parents having dwelt while he was young,
his uncle, Mr. Madison, a stockbroker in London, took
him into his care. He was educated at the Soho Square
Academy, celebrated for the annual theatrical performances
of the pupils, several of whom became distinguished authors.
He was afterwards entered a student of Lincoln's Inn, but
the fondness for theatrical amusements which he had contracted
at school was not to be subdued; he became a constant play-
goer, and directed his studies to the drama rather than to
the law. Having written a dramatic piece which was favourably
received, he at once entered upon the legal profession without having
been called to the bar.

Morton thenceforth devoted himself entirely to play-
writing, and became one of the most successful of modern
dramatists. Such was the evidence of managers in his power of pleasing an audience, that when his
comedy of 'Town and Country' was to be brought out in
1807, Mr. Harris, the leasee of Covent-Garden Theatre, gave
him 1000l. for the first three months before the rehearsal, taking on himself all risk of failure. Out of four-
teen or fifteen comedies, comic-operas, and farces, five or six
still continue to be stock-pieces at almost every theatre where
they are produced.

The following is a list of his plays, perhaps incomplete as
to two or three of the later productions: 'Columbus,' 1792;
'Children in the Wood,' 1788; 'Zorabki,' 1796; 'Way to
Get Married,' 1796; 'Cure for the Heart Ache,' 1797;

P. C. S., No. 127

Vol. II.—2 U
MOS 330

'Speed the Plough,' 1798; 'Secrets worth Knowing,' 1798; 'The Blind Girl,' 1801; 'School of Reform,' 1803; 'Town and Country,' 1806; 'Roland for an Englishman,' 1812; 'School for Grown Children,' 1826; 'Invincibles,' 1828.

Morton was a respectable man, of regular and orderly habits. His conversation was sprightly, and abounded in anecdotes; the knowledge of cricket tops all a companion; he was a constant attendant at the cricket-grounds, where he enjoyed his favourite exercise. He died March 28, 1838, in his seventy-fourth year, leaving a widow, three sons, and a daughter.

Morton's manner of writing left much to be desired; they only by reading them, his uniform and great success will probably be matter of surprise; to those who are engaged in dramatic writing, it must be no less a matter for investigation. Morton has not the correct construction of a dramatic artist, reduced deficient in the highest qualities of the art. He gives no true representations of character either in its broad and strong markings or in its nicer discriminations; he shows nothing of the real operation of motives, nothing of the genuine workings of feeling: his serious and his comic characters are alike artificial and exaggerated; they are strictly and peculiarly stage-characters, and anything resembling them in real life will rarely if ever be met with. But he has extraordinary dramatic tact: he foresees distinctly what may be effected in the performance, and the situations, as well as the characters are admirably contrived for displaying an actor's skill, abundant in his imaginative powers and bursts of passion, overflows of excessive liveliness, or exhibitions of strange peculiarities, such indeed as have never been witnessed, but which, when well performed, are exceedingly amusing. He has neither the wit and little humour, but is never languid or heavy; and the very speeches which when read produce a smile of contempt or a feeling of incredulity, in most persons would, to Lewis, Murray, Quick, Haward, Emery, John Kemble, and Edmund Kean, the medium by which they were enabled to exhibit the triumphs of the actor's art.

(Gentleman's Magazine, 1838; Biographia Dramatica, by Baker, Reed, and Jones; Inchiata's British Theatre.)

MOSES, GEORGE MICHAEL, R.A., gold-chaser and enameller, the first keeper of the Royal Academy of Arts in London, was born at Schaffhausen in Switzerland, in 1704. He came young to London, and was first employed as a chasing in gold and also in brass for the ornaments of cabinet-work, in which he obtained a great reputation. He was also an excellent medallist and a good painter in enamel, but he did not carry his works in this respect much beyond enamels for watchcases, in one of which he painted, for the king, George III., portraits of the Prince of Wales and the Bishop of Osnaburg. He was long keeper at the Royal Academy, and who by virtue of his office is principal teacher of the students: the superintendence of and the instruction in the antique aca- demy are the principal duties of the keeper. Before the foundation of the Royal Academy Mr. Moses was for many years treasurer and manager of the private academy in St. Martin's Lane. He died in the beginning of 1783, and Sir Joshua Reynolds wrote an eulogium upon him, which is printed in his Works. Lady Blessington says, Sir Joshua says Sir Joshua, Moses was the first in his profession; and he had a universal knowledge in all branches of painting and sculpture. ' He may truly be said,' he continues, 'in every sense to have been the father of the present race of artists. Hogarth, Rysbrack, Roubiliac, Wills, Ellis, and Vanderbank, were Moses's early companions, all of whom he outlived.

Mary Moses, his only daughter, was a very distinguished flower painter, and is the only lady, besides Angelica Kauff- man, who has ever been elected an Academician: she became afterwards Mrs. Lloyd. Miss Moses, says Smith, in his Life of Nollekens, was somewhat precise, but was at times a most charming woman. She was the daughter of Mr. Moses, a letter was sent to him by his daughter to Mrs. Lloyd, the wife of the gentleman to whom she herself was afterwards married; and the other to Fuseli while in Rome, of whom she said was said to be an admirer. In one of these letters according to the absurd figurations of the beginning of the reign of George III., she says, 'Come to London and admire our plumes; we sweep the skies! a duck's coat is six feathers, a lady four, and every milkmaid one at each corner. Now a monstrous cap, I pray tell your operator, that your hair must measure just three-quarters of a yard from the extremity of one wing to the other. The second is chiefly on Lord Chesterfield's advice to his son; she says to her father, 'You have read Chesterfield's letters, give me your opinion of them, and what you think of his lordship: for my part I admire wit and admire good manners, but at the same time, I should detest Lord Chesterfield's advice."

Believe me, if you have met with more amusing letters, I should wish to have seen them; if you have not, I am happy to have been your family reader."

Reynolds was like himself in pictures which you have seen; Gainsborough beyond himself in a portrait of a gentleman in a Vandyck habit; and Zoffany superior to everybody in a large picture of a street in London. In reading these two other figures, Subtle and Face. Sir Joshua agreed to give a hundred guineas for the picture; Lord Carlisle half an hour after offered Reynolds twenty to part with it, which the knight of knighthood, the eminent and highly thought of, agreed, and tendered it to the lord, and the encomium to his brother artist. He is a gentleman! Angelica made a very great addition to the show, and Mr. Hamilton's picture of Britis parting from Achilles was very much admired; the Britis in taste, &c., &c., as usual.

Mary Moses decorated an entire room with flowers at Frog- more for Queen Charlotte, for which she received 900l.: the room was called Miss Moore's room. After her marriage she practised only as an amateur: she died at an advanced age in 1819. West was reinstated in the chair of president of the Royal Academy in 1808, then in 1812, and again in 1828, and when Fuseli was taxing with having given it, he said, says Knowles, his biographer, 'Well, suppose I did; she is old and ugly, and does not; and is not one old woman as good as you and me?' West and Fuseli were the most celebrated men in the MOSQUITO COAST. This country, which has now taken a place among the independent countries of the American continent, is situated between 11° and 17° N. lat., and 85° and 86° W. long. Along the coast of the Caribbean Sea it extends from the mouth of the Roman River (15° 6' N. lat. and 85° 46' W. long.) to Punta Gorda and the mouth of the Rama River (11° 30' N. lat. and 83° 47' W. long.). The sovereign of the country also claims the country farther south, lying between Punta Gorda and the Chiriqui Lagoon, but the states of Costarica and Nicaragua dispute those claims. The line which separates the territories of the Mosquito Coast from the states of Honduras, Nicaragua, and Costarica, is not well determined; it is however presumed that it runs along the chain of mountains which traverse this part of America from south-east to north-west, and which is very imperfectly known. In such circumstances we must presume that the estimate of the area of the country, which without the disputed parts is stated to be 26,000 square miles, and including the disputed districts, 34,000 square miles, is only to be considered as a vague approximation to the truth.

The most northern portion of the coast-line of this country, or that which extends from the Roman River to Point Patock, is high, but the remainder of the shore is low. Along this low line of coast a series of keys occur from ten to thirty-five miles from the main. There are some that have not been experienced navigators, but shelter that narrow part of the sea which lies between them and the mainland from the ocean swell, so that it can be navigated without danger by coasting vessels, as the depth of water varies between seven and fourteen fathoms. Vessels sailing from Jamaica to Cape Gracias a Dios pass between the islands of Old Providence and St. Andrews, and enter the above-mentioned channel by the wide opening in those parts between the keys.

From the mountain-range which forms the western boundary of the country several lateral branches run off, which terminate at the distance of eighteen to twenty-four miles farther to the main. These branches are the highest when from 1000 to 1500 feet above the sea-level, but they are very imperfectly known, with the exception of the most northern, which comes close up to the shore between the Roman River and Cape Patock. In these parts are several high peaks, as Carib Peak, which is about 4000 feet, the Poyas Peak, 3500 feet, and the Sugar-Loaf, 3000 feet above the sea-level.

Along the low coast the country is a level plain, slightly elevated above the sea, but on proceeding farther inland it rises in terraces, and here the plain is frequently interrupted by depressions and by elevated tracts which are connected with the sea by narrow passes. These passes are usually scooped out by the currents of the rivers. The lower por-
tions of the country are savannahs, without trees and frequently without bushes, but where the country rises and forms hills, it is overgrown with trees. In the vicinity of the sea the soil of the country is sandy and rather shallow; nevertheless it produces excellent grass, which is ascribed to the waters which inundate this part of the country during the rainy season. Farther inland these plains have a richer soil, which is benefited by the rich deposits of sand, and the large piece of black mould. The higher ground, especially near the banks of the river, and the lagunes, have a large mixture of sand, and these tracts are mostly overgrown with pitch-pine, fir and larch trees, which are mixed with mould, and in the woods which cover them a large number of mahogany-trees, cocoa-trees, casouchette, and other valuable trees are met with. The whole country, as is known, presents a continual alternation of wooded lands and prairies.

The Mosquito Coast is drained by numerous rivers, which south of Cape Gracias a Dios run mostly to the east-south-east, but north of it they run north-east. Many of them are navigable to a considerable distance from their mouths, and it appears that rapids are only found near their sources. But the navigation is frequently impeded by the trees which are brought down during the rains, and when the water descends, they are lodged in the bends of the river, where they are accumulated so as to form a dyke across the current. They are partly removed by the freshest, but are soon replaced by others. Most of the lakes are divided by low, 24-5 feet, harbours, which however, are only accessible to small vessels, as all those which do not fall into lagunes have bars across their mouths, on which at low-water there are in general only from one to two feet of water. In the rainy season the bars are partly removed, but the eastern trade-winds soon throw them up again, when the rivers have sunk to their lowest level, and the diminished force of the current cannot carry the matter far into the sea. The Belfield River, which falls into the lagune of the same name (12° N. lat.), is said to run to upwards of ninety miles, rises within the state of Nicaragua. Wanks or Segovia River also rises in Nicaragua, where it is called the town of Matagalpa and Segovia. It is said to run 250 miles. Its mouth is near the Bay of Cape Gracias a Dios, and has a bar; but the river may be entered by a canal which unites it to the sea. It is said to be navigable to the boundary-line of Nicaragua.

The lagunes are a peculiar feature of this country. They are not shallow, stagnant collections of water, but deep lakes, connected with the sea by one or more straits, by which the tide enters them. They generally receive one stream, frequently several streams, and therefore a current is always observable, which sometimes runs strongly. Near the entrance of the lagune, and especially near the mouths of the rivers, it is quite sweet. These sheets of water always extend parallel to the coast, and frequently approach one another, so that the natives in their canoes of 10 or 15 feet long and 3 feet wide are not encumbered by the shallow water of the lagunes. The lagunes form good harbours, but towards the middle of the dry season bars are found across the entrances, which however have much more water than the bars of the rivers. Owing to this circumstance, and because the lagunes do not exhalate any dangerous vapours, the settlements have generally been made on their banks. The most extensive, from south to north, are Belfield Lagune, into which the Belfield River falls,—this lagune is upwards of fifty miles long, and from eight to fifteen miles across, and has from three to four fathoms water on its bar; Pearl Key Lagune, where the sunken reef appears from one to three miles wide; the bay at the Cape Gracias a Dios, which is of small dimensions, being only four miles long and three wide, which forms a good harbour, with 22 feet water at the entrance, and 17 feet in the innermost part; and Carataska Lagune, west of Cape Gracias a Dios, which is thirty-six miles long and from eight to ten wide, and from two to three fathoms deep: the bar across its mouth has only eight feet water to the entrance of the lagune, which separates the lagune from the sea is a narrow channel, from two fathoms to two and a half deep. Four rivers of moderate size fall into this lagune.

Vegetation is more luxuriant than in any country between the tropics. The grasses which with the savannahs are clad often attain a height of five or six feet. The number of vegetables which are cultivated with success is great; the most common are yams, manioc, cassava, sugar-cane, rice, maize, tobacco, sweet potatoes, yams, casava or mandioc. Coffee, cocoa-nut trees, palm, oil trees, and orange and lime trees are planted; the woods contain a great number of trees whose fruits are edible, or which afford timber and cabinet-woods, or are useful in other respects. Such are the pine-apple, cabbage tree, banana tree, tan palm tree, caoutchouc tree, avocado pear, pimento tree, live oak, sapotilla tree, papaya tree, calabash tree, mammea tree, guava tree, mango grove, cacao tree, silk cotton tree, mahogany tree, cedrelle, yellowwood tree, ironwood tree, dogwood, ebo tree, casheew tree, lassa tree, mango, jacaranda, cocoanut, maguey, and brasilletto tree, and a few others. In the woods the indigenous plant is found wild; vanilla and sarsaparilla are gathered, the last mentioned to such an extent as to afford a considerable article of export.

Cattle are very numerous and of a large size; horses abound, but are not kept, but boats are abundant. Fowls are numerous. Several species adorned with brilliant plumage are found near the rivers, where also the jaguar and the tiger are met with. Other animals are the racoon, the opossum, grey squirrels, deer, and the manati. Alligators are found near the embouchures of all the rivers, but of these very large according to their different species. They are distinguished by its size, and is eaten by the natives. There are several kinds of snakes, four of which are stated to be poisonous. The land-turtles belong to the species Testudo tabulates, and are sometimes more than a foot long, but their size varies from one to two feet.
flesh is less esteemed than that of the sea-turtles, of which great numbers are always to be met with on the keys opposite the coast of Casbar, the 227 Ceylonese resort, where they take especially green turtles (Chelonia midas) and hawks-bills (Chelonia caretta). The birds are imperfectly known. Among them are different kinds of pelicans, the caya (Pelecanus occidentalis), humpbacks, the black vulture or John crow (Cathartes hartii), and several kinds of pigeons. Several kinds of ducks and the pelican (Pelecanus fuscus) have been noticed. Fish is abundant in some of the rivers. Fifty miles up the course are caught in the sea, thirteen in the lagunes, and perhaps more than ten in the rivers. The shark and the saw-fish (Pristis antiquorum) are frequent in the sea and the lagunes, and along the coast the mygale (Blaas or Bande) is not uncommon. Crabs, crawfishs, and some kinds of lobsters are frequently met with. Honey is frequently used as sugar. Mosquitoes are not uncommon, which is ascribed to the strong winds that generally blow. Sand-flies, sand-dresses, and centipedes (Scolopendra morrisoniana) are common.

The majority of the inhabitants do not materially differ from the other savage tribes of America. But the ruling tribe, called Samboos, show evidently a strong mixture with the negro. The colour of the other tribes is a clear brown; but that of the Samboos is much darker, approaching sometimes to black; and whilst the black hair of the forerunner is that of the negro, the Samboos in some cases have a redder countenance. The Samboos have also thicker lips, and are stronger built. There exists a tradition, that a vessel containing a great number of negroes was cast away on this coast, that the negro males were cast ashore, while the women and negro girls were carried away. Among them are also a few Caribbees, probably the descendants of those who, in 1797, were sent from the island of Dominica to that of Rostan, and who afterwards emigrated to the continent of America. They are shorter in stature than the other tribes, but stronger built, have a somewhat convex nose, and are distinguished by greater vivacity and industry. All the tribes, though they speak different dialects, distinguish themselves from other nations by the name of Miskitos, which the Europeans have changed into Mosquitoes. The natives of this country live mostly on the produce of their fields, on which they cultivate maize, cassava, yams, plantains, pineapples, coconut-trees, and some other fruits; but they eat also large quantities of fish, and the flesh of the wild animals which they kill, or of their cattle. They show considerable skill in making canoes, of which the larger kind, called dories, are frequently six or eight feet wide, and from thirty to forty feet long. They are made of a single trunk of a tree. Though in general very indolent, the natives are good seamen, and are esteemed by the Spanish officers who have employed them and their canoes. They have also acquired some skill in weaving cotton-stuffs.

The commerce of the Mosquito Coast is carried on by a few vessels, which are settling. They receive European goods for the market, commonly from Belize, but also by vessels sent from Jamaica and some English settlements in the neighbourhood. Vessels from Jamaica and the Cayman Islands to the keys along the coast to catch turtles, also import occasionally a few articles. In this manner the natives are supplied with some coarse linen and cotton stuffs, with very indigent guns, gunpowder, balls and shot, some cutting instruments, as axes, knives, blades, iron kitchen utensils, fishing-hooks, glass beads, gossamer hats, American tobacco, pipes, flints, girdles, bows, and mugs of earthenware, rum, brandy, and liquors. These articles are exchanged for cattle, especially cows, turtle-shell, hides and horns, cassava-rolls, vanilla, caustichoue, gummni, cacao, pimento, castor-oil, nuts, mahogany, fustic, and some articles from the central American states: as cochineal, silver, gold-dust, and silver and gold. At the keys the tributaries of the rivers have some intercourse with Honduras and Nicaragua.

This coast was one of the first places where the Spaniards tried to form a settlement. Alonso de Ojeda and Diego de Nicuesa landed here in 1512, with about a thousand adventurers; but the natives resisted the invasion with great perseverance, and the Spaniards were compelled to leave the country after having lost a considerable number of men. When the Spanish entered the country in 1525, several of the remote districts have had some intercourse with Honduras and Nicaragua.

All these events increased the hatred of the natives to the Spanish name. When the buccaneers were in power in the seventeenth century, they were received by the Mosquitoes with open arms. In the country as the safest retreat when they were pursued by the Spaniards. By means of the buccaneers it appears these people were brought into connection with the English, and the first protection given to this coast by the English, was confirmed by a treaty in 1670. The first settlement of Englishmen on this coast dates from 1750, when some families established themselves at Cape Gracias a Dios on Black River and BЉveda. They were not in a certain degree of prosperity, especially by smuggling with the inhabitants of the Spanish colonies, the English government sent them some persons invested with authority, and erected a few small forts. These were noticed, early enough to be engaged to abandon these forts and to compel the colonists to leave the country. This was done, but several families established on BЉveda's Lagoon did not obey the order of their government, and remained there. It is stated that in 1770 the number of English settled on the Mosquito Coast amounted to 1400 individuals. These people were entirely abandoned by the peace of 1783, and were obliged to go to Belize. Soon afterwards the Spaniards made the last attempt to conquer the coast, by taking possession of the fort on Black River, which the English had abandoned. But they were totally defeated by the natives. England again took the coast under its protection, in 1854. The Spaniards acquired their independence, that of Nicaragua claimed the Mosquito Coast as a portion of its territories, but these claims were rejected by England and the king of the Mosquitoes. It was then that Spain, in 1856, treated the king as an independent sovereign in 1817, when he paid a visit to the town of Guatemala. It appears that at present the claims of the state of Nicaragua have been given up, with the exception of the Spanish portion of the country lying between Punta Gorda and the Lagunas of Chiquiri. Meanwhile the king, whose power is absolute, has ceded different districts with almost sovereign power to some Englishmen, who have formed settlements on BЉveda's Laguna and on the banks of Black River, but other portions have not yet been settled. It is probable that in course of time this country will become an English colony, considering that the native population has lately greatly decreased, nearly half of it having been swept away by the small-pox.

(Henderson's Account of the British Settlement of Honduras,) &c.; Robert's Narratives of Voyages and Explorations on the East Coast and the Interior of Central America; Young's Narrative of a Residence on the Mosquito Coast during 1833-1841; and Bericht liber die Untersuchung einiger Theile der Antilibern am Rande von der dazu erlauterten Commission, Berlin, 1845.)

MOULFON, [Sheep, P. C.] MOVING POWERS. The means employed to give motion to machines is generally of the cases in which the force of gravity is applied directly, as in turning the cylinder of a clock, are the strength of men and animals, the pressure of the atmosphere, the expansive force of steam, and the action of wind or water; it is even probable that the recently posited actions of the galvanic fluid and of fired gunpowder will in time be numbered among motive forces for impelling carriages, vessels, or machines. The first and second of the powers above named have been treated under Animal Strength, P. C. S. and Atmospheric Railway, P. C. S.; and the force of steam under Steam-Engine, P. C. P., p. 478 et seq.

The intensity of a moving power is always estimated by the amount of the resistance which is overcome and the space through which the equivalent of that resistance is conveyed, or raised vertically, in a given time. Thus, in the article on Animal Strength [P. C. S.] it has been shown that a man, a horse, &c. can do work in the course of a year, or, to put it another way, in the course of a year, or, to put it another way, supposed to be continued during all the time that the machine is at work.

Originally the larger kind of engines, except such as were impelled by sails, were of wood, and were very expensive; and when other agents were employed, the gross effect of the
engine was estimated by the number of horses to whose action it was equivalent; but the intensity of horse-power is very variable, and some inconvenience was at first, on that account, experienced in estimating the relative values of engines. In order to establish, conventionally, this dynamical unit, Messrs. Boulton and Watt ascertained from trials purposely made that a strong horse can draw 125 lbs. at the rate of 3 miles per hour during 8 hours; therefore the measure of the power may be expressed by \(3000 \text{ lbs.} \times 3 \times 8\) or, multiply by 5280, the measure is 15,840,000 lbs. raised one foot in an equal time. This product, being divided by the number of minutes in 8 hours, gives the rate of power for one horse equal to one foot per minute continually; and the last number is now universally adopted as a measure of the intensity of the power of a horse. Therefore when an engine is said to have the power of any number \(n\) of horses, it is understood that it is capable of raising 38,300 \(n\) pounds' weight to the height of one foot in every minute during the continuance of its action.

The method of estimating power by a weight carried or raised through a certain space in a certain time is capable of being applied to all engines: thus, in drawing a carriage along a road, the resistance of the carriage must be equivalent to some weight; and the re-action of water against the paddles of a steam-boat may be equally represented by a certain weight which, if it were lifted by the wheel, would oppose a resistance equal to that of the water. For the useful force of steam-engines in terms of the volume of water evaporated, the pressure of the steam, the length of the stroke, etc., see Steam-Engine, P. C.

Wind and water are employed as prime movers by means of the momentum arising from their velocity; and the latter, occasionally, by the pressure arising from its weight. The manner in which the force of wind is made to act in giving motion to vessels on the surface of water has been fully explained under Sail, P. C., and, in producing the revolutions of windmill sails, under Wind-Sail, P. C.; it is intended therefore, in this place, merely to explain the method of forming an equation of equilibrium for the power of an oar in giving motion to a vessel, and to show how the force of waves on the paddles or float-boats of wheels which are turned by that element.

Let \(M N\) represent one side of a vessel, \(A B\) the position of the oar when its blade enters the water, and \(E\) the fulcrum or side of the rowlock against which it presses; then the vessel will remain at rest in the water if the oar, during the time that a stroke of the oar is being made, let \(F\) be the position of the fulcrum and \(C D\) the position of the oar at the end of the stroke; if the vessel had remained at rest, the oar, at the end of the stroke, would have had the position \(c\), of which may be considered as parallel to \(C D\).

Now, \(B\) being the centre of percussion on the blade of the oar, the actual motion of \(B\) (supposed to be parallel to the keel of the vessel) may be represented by \(DB\) while the movement of the vessel is \(EF\) (\(= DT\)); and therefore \(DB\) represents the relative movement of \(B\). The lines \(BD\) and \(DB\) being proportional to the velocities of the oar and vessel, which velocities we may represent by \(\alpha\) and \(\beta\); \(\alpha - \beta\) will express the relative velocity of the oar, and the effective power of the latter will vary with \((\alpha - \beta)^3\). Let \(a\), in square feet, be the area of the blade of an oar, and let the pressure of water against a square foot of surface be 14 lb. when the velocity is 1 foot per second; then \(\frac{a}{2}(\alpha - \beta)^2\) will denote the force of the oar.

If, for simplicity, the prow of the vessel be supposed to have the form of a triangle with plane faces meeting in a vertical line, or cut-water, on putting \(a\) for the area of the whole prow and \(\theta\) for the inclination of each face to a vertical plane passing through the keel, we shall have

\[
3a' \sin \theta \cdot \alpha^2
\]

for the resistance of the water against the prow. Therefore, if \(n\) be the number of oars all of which are supposed to act with equal forces; we have, when the vessel has acquired a terminal velocity,

\[
\alpha = \frac{3n}{8} \sin \theta \cdot \alpha^2
\]

from which \(\alpha^2\) may be found. The velocity of a vessel moved by oars is, however, found to increase in a less ratio than the number of oars.

The power of the oar in rowing appears to be diminished by the reaction of the feet of the rowers in pressing against the foot-boards; this has a tendency to force the vessel backwards, but it is compensated by the greater velocity which the centre of percussion of the vessel obtains. The oar is, however, in losing in overcoming the inertia of the oar, and in bringing it forward against the air; this last force is considerable when the vessel is rowed against a high wind, though it is to a certain degree diminished by the practice of feathering the oars.

The above equation might be used to determine the velocity of a vessel impelled by steam, in which paddle-wheels are employed. If it were possible to determine, early, the value of \(na\), or the number of square feet of paddle which, on both sides of the vessel, are at every moment acting efficiently against the water: the value of \(\alpha\) would be, of course, determined by the number of revolutions with which the wheel makes in a given time; and it should be expressed by the number of feet per second which the centre of percussion in the paddle moves through in turning about the axle.

The momentum of the vessel being horizontal against a plane, such as a flat-shaft of an undershot wheel, depends on its velocity, on the area of the surface with which it comes in contact, and on the obliquity of that surface to the direction of its motion; and, in estimating the effect of water on such a wheel, it is necessary to determine from the dimensions of the channel and the velocity of the water in it the weight of water which descends vertically through a certain height, as one foot; the product of this weight multiplied by the height actually descended, being compared with the product of the number of pounds which the wheel can raise to a certain height in the same time multiplied by the height, expresses the ratio of the power to the effect. From many experiments Mr. Smeaton concluded that, when the quantity of water expended is the same, the useful result varies nearly with the head of water, or with the square of its velocity.

The power of an overshot wheel is estimated by the product of the weight of water expended in a given time multiplied by the whole weight of its descent, that is, by the sum of the diameter of the wheel and the height of water in the reservoir above the top of the wheel. The useful effect of an overshot wheel is said to be nearly double that of one which is undershot.

In determining the power of water on breast-wheels, it is customary to consider the pressure of a wheel as equal to the weight of an undershot and of an overshot wheel; and its effect is conceived to be equivalent to that of an undershot wheel whose head of water is equal to the difference in height between the surface of the water in the reservoir and the height of the water impinging on the wheel, together with the effect of an overshot wheel whose height is equal to the difference between the point of impact and the level of the tail-water.

MUCID ACID. [CHEMISTRY, P. C. S.]

MUCIUS SCAEVOLA. [SCAEVOLA, P. C.]

MUCUNA, a genus of plants belonging to the natural order Leguminosae. The caules is campanulate bilabiate, with two very caducous bracteoles as long as the tube; the upper lip broad, entire, and obseous; the lower lip trident, with acute segments. The corolla is papilionaceous, with a corolla vexillum incumbent on the wings, much shorter than the wings and the keel, and without callostylles. The stamens are disiahiths, with five of the anthers oblong, linear, and the other five ovate and hairy. The seeds oval, roundish, or reniform, with a narrow, oblong, or linear hilum. The species are climbing herbaceous, with phylline and trifoliate leaves and axillary racemes, which hang down when bearing fruit.

\(M. prurieta\), Cowitch, has purple flowers in compact ovate racemes, leaflets hairy beneath, the middle one rhomboid and obtuse, the lower ones dilated to a sessile ovate and the other five ovate and hairy. The seeds oval, roundish, or reniform, with a narrow, oblong, or linear hilum. The species are climbing herbaceous, with phylline and trifoliate leaves and axillary racemes, which hang down when bearing fruit.

\(M. prurieta\), Common or Stinging Cowitch, has entire ovate acute leaflets, smooth above, hairy beneath, the lateral ones oblique at the base, the middle one slightly rhomboidal
The racemes are from 1 to 1½ feet long, lax, and many-flowered. The calyx is hairy, pink, with narrow laciniate segments which have a diagnostic smell, the vexillum is flesh-coloured, the wings purple or violet, and the keel greenish white. The legumes about 3 inches long, the thickness of the finger, closely covered with strong brown hairs, are oblong, variegated with black and white hilum. A mixture of the hairs of these two species form the Cowitch of commerce. The ripe pods are dipped in syrup, which is scraped off with a knife, and when the syrup is removed, which is the result of the growth of the hairs becoming mixed with it, it is used as a medicine, and is considered a good astringent, as it occasions no uneasiness. It is given from a tea-spoonful to a tablespoonful in the morbus choleraeum. When applied to the skin, produce an intolerable and painful itching. A vinous infusion of the pods, twelve to a quart, is said to be a certain remedy for dropsy. A strong infusion of the roots, sweetened with honey, is used by the native practitioners in India in cases of cholera morbus. It is likewise considered a powerful diuretic.

M. urens has racemose flowers and legumes clothed with stinging bristles; the leaflets have a shining tomentum beneath. The flowers are large, white or yellow, with the lower edge of the wings red. The seeds, from their resemblance to an eye, are called by the French Xyces yeux. The name has been proposed for the genus, but the seed has the name œil-œuf in our colonies in the West Indies, where the species is a native.

A rich soil suits these plants, and they are easily raised from seed. They are not worth the trouble of cultivation, except for botanical gardens.

(Don, Gardener's Dictionary; Lindley, Flora Medica; Bentham, Outline of Botany, P. C., 1856; MULE, MULLE-JENNY. [Cotton Spinning, P. C., p. 96; Cotton Manufacture, P. C., p. 98.]

MULGE DIUM, a genus of plants belonging to the natural order Compositae, the suborder Liliiflorae, and tribe Cicurineae, which subtribe is called Herzicæ. It has many-flowered heads, a double involucre, the inner of one row, the outer of short lax inbricated scales; the fruit compressed, constricted above, and terminating in a dilated disk; the outer rows of the pappus rigid and brittle. There are several species of this genus.

M. alpinum, has glabrous, lyrate at the base, arrow-shaped leaves, the terminal leaf large triangular-hastate acute; the stem simple, heads racemose, bracts, peduncles and involucres glandular, hairy; the fruit oblong, not attenuated, with many ribs. This plant has blue flowers in small numerous heads, with yellow disk, 2½ feet high. It is perhaps a true species or a hypogeous form of one; it belongs to the genus M. alpinum, and is the only British species of the genus. It is the Sonchus carvulans of Smith in the English botany. The only locality in which it grows in Great Britain is the mountainous districts north of the Forth.

M. floridum is a native of America, and on account of its excessive bitterness, is called Gall of the Earth.

(Rabbiton, Manual; Lindley, Vegetable Kingdom.)

MULLER, Peter, a German engraver, known for his numerous prints, after drawings by the early Italian masters. He was born at Florence towards the close of the eighteenth century, and was the pupil of A. Scacciat, whom he assisted in a series of engravings after the most beautiful drawings in the Florentine Collection. Forty-one only were executed during Scacciat's life; the remaining fifty-nine were executed entirely by Muller. These were succeeded, in 1775, by a collection of prints after drawings of the earliest masters, from Cambiace to Pietro Perugino, under the title Istoria Pratica dell Incominciamento e Progresso delle Incisioni in Europa. In 1780 his name appeared in a list of disegni originali esistenti nella Galleria di Firenze; which was followed, in 1780, by a still more interesting work on the five great Italian schools of painting, Segni e Stampe delle Cinque Scuole di Pittura Italiana....

MULLER, the name of two very celebrated German engravers, father and son.

MULLER, Johann Michael von MULLER, the elder, was born at Bernhausen, near Stuttgart, in 1747. His father, who held an official situation under the government of his native country, wished to educate Muller for the church, but the youth showed such unusual talent in the arts, that in 1764 he entered the well-known Academy for the Arts at Stuttgart, that the Duke himself urged him to follow art as his profession. Accordingly, in 1764, Muller, under the immediate patronage of the duke, undertook the engraving of the new edition of the Encyclopædia, recommended him to follow engraving, which he pursued for six years (1770-76), at Paris, under Wille, with such success that, in 1776, he was elected a member of the French Academy. He remained in the service of the Duke of Saxe until 1780, when he went to Paris, and was admitted to the academy. His last work in Paris was a good portrait of his master J. G. Wille. The first work which he completed at Stuttgart was Alexander, Conqueror of Himself, after Flinck, which he took, in 1781, to Paris to be printed, not venturing to work off so valuable a plate at the then inexperienced copper-plate press established by himself in Stuttgart. In 1785 he was invited to Paris to engrave the portrait of Louis XVI, painted in 1774 by Duplessis; but the picture from which Bervic engraved the same king was painted ten years later, and Bervic's is accordingly a more characteristic portrait of what he eventually was. In 1802 Muller was elected a member of the French Academy, and in 1803 was one of the artists who conducted the exhibition of the works of art for the Société des Arts. In 1808, he was elected a corresponding member of the Academy of Sciences at St. Petersburg, and in 1818 was elected a member of the French Academy. He died at Dresden in 1818, and in the same year a biography of him was published in the Schwäbische Merkur, No. 71.

Muller engraved only thirty-three plates, a small number, but some of them are the large and elaborate works; they are, however, chiefly portraits. His principal works, besides those already mentioned, are—the Battle of Bunker's Hill, after Trumbull, engraved in 1789; the Madonna della Seggiola, for the Musée Français, engraved in 1804, by many considered superior to the print of the same subject by Raphael Morghen; a St. Catherine, with two Angels, after L. da Vinci; and the portrait of Schiller, after A. G. Christian Friedrich von Müller surpassed his father, but, owing to the extreme shortness of his career, his prints are even less numerous than those of the elder Muller. He was born at Stuttgart, and was marked in his youth by a marked facility for his art. He removed to Dresden in 1816, aged only thirty-three. He was carefully educated by his father in all those branches of the arts which, by his own experience, he knew to be requisite to constitute an excelent engraver; and in 1809 he had the good fortune to spend his studies in the great world at Paris, where at that time the majority of the finest works of art in Europe were collected together in the Louvre. Here, in 1808, Muller engraved the St. John, which he dedicated to the Revolutionists, after Domenichino, in which the eagle brings him his pen; and Adam and Eve under the Tree of Life, after Raphael. He was commissioned shortly afterwards by Ritter, a printseller of Dresden, to engrave his last and greatest work, the most sublime of all the paintings of Raphael, the Madonna di San Sisto, in the Dresden Gallery. He was wholly occupied for the remainder of his short life on this plate, which he meant to complete, but he never saw a finished print from it. He removed to Dresden in 1814, and was appointed professor of engraving in the academy there. His existence seems almost to have been wrapped up in the execution of this plate; he was occupied with it at night and at the table, and the infallible result of such constant application and excitement soon made its appearance; he was in vain advised to desist for a while from his work. He completed the plate in 1816, and sent it to the academy; but the public excitement which supported him departed also; he had just strength enough left to admit of his being carried to the Sonnenstein, near Pirna, where he died in 1816, only a few days after the arrival of his plates at Dresden. It was suspended over the head of his bier as he lay dead, thus reminding us of the similar untimely fate of the great master of above, whose head, as he lay in state, was hung also in his last work, the Transfiguration. Muller left a wife and two young children.
Christian Müller engraved only eighteen plates, but the Madonna di San Sisto is in itself a host, and exhibits him at least the equal, if not the superior, of Raphael Mengs, to which the_great-novels of Mengs, of which the first volume, on Orchomenos and the Minyas, ('Orchomenus und die Minyer,' 1820), is a famous work of the first volume, on Orchomenos and the Minyas, ('Orchomenus und die Minyer,' 1820, 5vo.), it was in consequence of the advice of Heeren and a recommendation of Mommsen, that he was invited to a professorship in the university of Göttingen, with the special object that he should lecture on archaeology and antiquarian art. His activity created a new era in the history of German archaeology, and under his influence the study of philology and art criticism received an impulse, which was soon felt in all Germany, and was extended over a great part of Europe by the valuable works published by Müller in rapid succession. In order to show the extent of his knowledge of art and science, he spent in 1819 some time in Dresden, and in 1822 he visited France and England. But although his attention was more particularly directed to antiquities, he never lost sight of the fact that the arts of the ancients represented only one side of their intellectual activity, and formed only one source among the many from which a complete knowledge of antiquity is to be derived. In order to show fully the connection of religion, manners, politics, and history, in the case of one of the Greek races, Müller wrote his work on the Dorians ('Die Dörser,' 1824, 2 vols., 5vo.), which forms the second and third volumes of 'Geschichte der Helladischen Stämme und Städte,' and was translated into English by H. Tuffnell and G. C. Lewis, Oxford, 1830, 2 vols., 8vo., with various additional notes.

A new edition of the 3 vols. of the whole work has been published since Müller's death by F. W. Schneedewin, Breslau, 1844, and a new edition of the English translation of the 'Dorians' appeared in 1840. Müller intended to continue this series of works by a history of Attica, but certain scruples induced him to defer the execution of this task, and it has unfortunately never been executed. The year after the publication of the 'Dorians' Müller published his Introduction to a scientific system of Mythology ('Prolegomena zu einer wissenschaftlichen Mythologie,' Göttingen, 1825, 8vo.), of which an English translation by J. Leitch was published in London, by the British Museum, and sold at two guineas. In 1826 he published a Manual of the History of Art ('Handbuch der Archäologie der Kunst,' Breslau, 1830; a second edition appeared in 1832). This last work was the first of the kind that had been produced in Germany. The work was at once a success, and was in a short time translated into French and Italian. The work has been published in Germany under the superintendence of his brother Julius Müller. Besides these greater works Müller also wrote 'Minerva Pallasias Sacræ et Aedem in Arce Athenarum stratæ,' 8vo., Göttingen, 1830; 'De Phidias Vita et Operibus,' Göttingen, 1827, and a great number of articles in periodicals and encyclopaedic works. The only correct edition of Festus that we have is that of Müller (Leipzig, 1835, 4to.), and the critical edition of Varro's De Lingua Latina (Leipzig, 1833, 8vo.), and of the Eunomies of Aeschylus, are equally valuable.

In 1840 Müller, who had long desired to see the countries to the investigation of whose history, literature, and art his whole life had been devoted, resolved to visit Italy and Greece, partly to convince himself of the correctness of the results at which he had arrived, and partly to collect new materials. This activity in Italy was very great. He lived in July 1841, while engaged in making some excavation at Delphi, he was seized with a fever, in consequence of which he died soon after he had returned to Athens. He was buried in the Ancient Academy at Athens, the most appropriate place for a scholar like Müller that could have been devised.

Müller was a man of the most extensive and varied acquirements, and of a keen and penetrating judgment. He acquired a European reputation at a comparatively early age. His numerous works, however, are not all of equal merit, and the two faults more particularly to be noticed are his great haste in the composition of his works, and a tendency to theorise and generalize on insufficient grounds. But in extent of knowledge and reading there scarcely ever was a scholar who surpassed him.

K Michael Müller, one of the best of the English landscapers, was born at Bremen in 1758. His father was a citizen and had been instructed in painting at the school of painting at Darmstadt, and his great teacher was nature: he found an early and valuable patron in Mr. Arman, of Clifton, for whom he painted many pictures. In 1785 and 1786 he made a tour upon the Continent, to France, Italy, and Spain, and collected many admirable sketches. Sketching from nature was a department of art in which Müller had extraordinary powers; nearly all his more considerable works of this class are in themselves complete; they require no elaborated copies to make them presentable as pictures; he did indeed elaborate very few of them into pictures, and some of these rather lost than gained by the process.

In 1838 he exhibited a picture of Peasants on the banks of the Rhine waiting for the Ferry-boat, but it was a piece of no pretensions, and attracted little notice.

In 1838 he started upon a long and arduous tour through Greece and Egypt, which brought him into contact with all the monuments of the Nile, and visited the mummy-caves of our adversaries, and many other interesting places in Greece and Egypt he made masterly drawings. He returned to England towards the close of 1839, and brought with him a rich and exact description of several admirable pictures of the remarkable scenes that he had sketched during this his first oriental tour. He had in the exhibition of 1840 Athens from the Road to Marathon, and the Memnon, or Ruins of Gournou Egypt at Sunæet, both pictures of the highest degree of merit, but in different styles. The Memnon, though hung high up in the dark octagon room in the Academy, commanded the attention of every one who could see them. It is a master-piece of colour and effect, and is certainly a work of high poetic art. The view of Athens is equally excellent in its class; the pictures of the Greek temples, and the landscape connected with the place make it an additionally interesting work: this picture, for which Müller received only thirty guineas, for his works had not yet attracted a moiety of the attention which he deserved. The Emperor of Russia had to make a large picture-dealer for nearly ten times the amount. The Memnon was sold for twenty-four guineas: ten times the amount is nearer its present value also.

In 1843 Müller purchased for his own account Sir Charles Fellowes on his last expedition to Egypt, to remove to London the Xanthian marbles, now in the British Museum. He returned to London in 1844 with some dozen of very interesting ancient objects, which excited the admiration of all who saw them at a meeting of the Graphic Society shortly after his return. About three hundred sketches and other works were lately sold by auction by Messrs. Christie and Manson, and they realized the enormous sum of
A small sketch of his own apartment at Macri alone brought sixty-five guineas. These are curious facts: he himself receives only thirty guineas for his picture of Athos, a finished master-piece; he died at his study, and a few months subsequently a small water-colour sketch of his own apartment, which probably he himself would not have valued at much more than thirty pence, is sold for more than double the original price; no living artist was ever known to appear so scarcely worth the shadow of his own body when dead. The pictures, the fruits of Muller's second oriental tour, which were exhibited at the Royal Academy in 1844, appear to have been considered as of very extraordinary and unexampled beauty, and unexampled death, though the fatal results of their bad hanging on the Academy walls betray an extraordinary degree of sensibility in the public. He appears from his own letters to have had a considerable and proportionate benefit from the exhibition of these works in the Academy; far indeed however was the result from the anticipation. Muller sent the following five pictures to the Academy exhibition of last year (1845)—Great Cannon formerly belonging to the Knights Templars, Rhodes; Head of a Cingari, Xanthus; The Berial-ground, Smyrna; Tent Scene, Cingaries playing to a Turkish family, Xanthus; and Turkish Merchants with Camels crossing the river Mangerelli, in the valley of Xanthus. These works were, with one exception, what is called hung out of sight; that is, either so much below or so much above the line, that they were not easily seen, and certainly would have altogether passed over by the majority of visitors to the exhibition. Muller felt this condemnation excessively, and notwithstanding his own professed resignation to his fate, he was equally anxious for the sale of his pictures as the artists who were seized in the beginning of the month of May, which ended fatally at Bristol, on the 8th of September following. He fled from enlargement of the left ventricle of the heart; and several of his friends have not hesitated to declare that the lumping committee of 1845 killed William Muller. In his own complaint however he was more moderate; he wrote as follows to his friends in the month of May, after the opening of the Exhibition:—"A man honourably leaves his house, his family, and his possessions, and plunges into large sums of money, and, after labour and fatigue, he returns to his home, and produces pictures acknowledged to be superior to his former works. His ambition leads him not to expect too high a reward—only places where his pictures may be seen. Such had been my hope; and I find my Turkish Burial-ground and Xanthian Tent Scene on the very top,—at least the first named of the large room, conspicuously obscure. My large picture is not so badly hung (six feet or more above the ground), but in such a place that one may expect but little from it..." The second of which I have received for the expenditure of large sums, of great labour, the risk of health, and a time of complete and exhaustion of a long journey—such are the rewards, or post of honour, a protected body afforded to the young English artist! the top row of the large room. These and other extracts from letters, and the 'Art BulletinJournal,' in which are also several letters written by him while in the East, containing a short account of his proceedings, and some interesting details relating to the ruins, and the customs of the people, in Asia Minor, illustrated with several sketches. Muller exhibited several pictures at the British Institution, among which were, in 1846, A View of Rhodes with the Fasha's Palace, and a Dance at Xanthus. He exhibited also many excellent landscapes in the early part of his career at Bristol; and, besides what have been already mentioned, the following works at the Royal Academy:—In 1841, Sketch of an Egyptian Slave market; Convent, Bay of Naples; and the Sphinx: in 1843, Arabs seeking Treasure: Prayers in the Desert; and Welsh Mill on the Dolgovry. He published in 1841 the entitled 'Pictureque Sketches of the Age of Francis I.' A select series of twelve, and a few will also shortly be published.

MUN, THOMAS, is the name of an English writer on painting, who lived in the early part of the eighteenth century, but of whose person history scarcely any thing appears to be known. His best known work, a small octavo volume, published at London in 1694, is entitled 'Discourse of the Causes of Painting, and our Foreign Trade is the Rule of our Trade.' Written by Thomas Mun of London, merchant, and now published for the common good by his son John Mun of Besterad, in the county of Kent, requires. This title-page comprehends nearly all the particulars we have been able to discover respecting Mun. The book is dedicated to Thomas, Earl of Southampton, in an address in which Mun's son says:—'It was left me in the nature of a legacy by my father, for whose sake I cannot but value my all beyond the common estimation, and as such I dedicate it to your lordship. He was in his time famous amongst merchants, and well known to most men of business for his general experience in affairs, and notable insight into the nature of foreign trade; of which he wrote a book, treating of the prince, and zeal to the commonwealth. The serious discoveries of such men are commonly not unpromising.' A discourse was accordingly given, indicating the nature and extent of Mun's dealings. Having observed that Ferdinand I., the Grand Duke of Tuscany, was very rich in treasure, and enlarged his trade by lending to merchants of Tuscany goods in the same manner by which, he says, 'I myself had 40,000 crowns of him gratis for a whole year;' although he knew that I would presently send it away in specie to Turkey, to be employed in wares for his country; he being well assured that in this course of trade it would return again, according to the old saying, with a duck in the mouth. By his thus encouraging of commerce, within these thirty years the trade of his port of Leghorn is so much increased, that of a poor little town, as I told you knew it, it is now become a fair and strong city.' Ferdinand I. died, after a reign of twenty-two years, in 1609; it is strange, therefore, that Mr. Macpherson, who quotes this passage in his 'Annals of the Commercial History of Europe,' in 1800, should have not been aware that the [name] mentioned above were killed in the month of May, which ended fatally at Bristol, on the 8th of September following. He fled from enlargement of the left ventricle of the heart; and several of his friends have not hesitated to declare that the lumping committee of 1845 killed William Muller. In his own complaint however he was more moderate; he wrote as follows to his friends in the month of May, after the opening of the Exhibition:—"A man honourably leaves his house, his family, and his possessions, and plunges into large sums of money, and, after labour and fatigue, he returns to his home, and produces pictures acknowledged to be superior to his former works. His ambition leads him not to expect too high a reward—only places where his pictures may be seen. Such had been my hope; and I find my Turkish Burial-
as having been 'the Pope's scholar in the seminary at Rome.' In 1852 he was one of the instruments in the detection of the Popish conspiracy; he was a witness against some of the prisoners. His body is smoothly, and boldly colored. The Count of Tiber the 26th and 30th days of May, 1852; gathered by A. M., who was there present. He had, it appears, held a dispute at the foot of the galleries with one of the 'pussies' of Munday's first publication. His tract called 'The Mirror of Mutability' had appeared in 1797; and he published, after this date, a large number of pieces in prose and verse, original and translated, in the 'Monist,' 'Literary and Scientific Journal,' 'The Grapher' and elsewhere. His dramatic productions are now more interesting than any of the others. He is said, but on equivoque authority, to have been a player and an unsuccessful one; he was act at a small theatre in the palaces of the government, and at a small theatre in the of the corporation and companies of London. Ben Jonson, in 'The Case is Altered,' written early in 1599, ridicules him and his city-shows, in his character of Antonio Badalino, making this personage to say of himself, that he supplies the place of peasant-poet to the city of Milan when a worse cannot be had, and that he uses as much state stuff as any man does. Perhaps Ben's critical acumen was a little sharpened by the fact that Munday had just been called 'our best poet' in 'Meres' 'Paladins Tamia,' in which Jonson's own name is not mentioned. Mr. Collier enumerates fourteen plays which Munday wrote, and then adds, writing, desiring to be added to this list the recently discovered, and called 'The Two Italian Gentlemen,' which he attributes to Munday, and infers to have been acted about 1584. The following other plays of Munday are mentioned, viz.: 'The Death of Earl of Huntingdon,' by Anthony Munday; 'The Death of Robert Earl of Huntingdon,' by Anthony Munday and Henry Chettle, both acted in February, 1598, and printed in 1601. Both are reprinted in Mr. Collier's 'Supplementary Volume to Dodge's Old Plays.' They are rude and irregular pieces, possessing much vigour of painting, and presenting, in the scenes with Robin Hood's band in Sherwood Forest, some pleasing poetry. It, 'The Death of Charm,' acted in July, 1609; and supposed to be the comedy of 'The Puritan, or the Widow of Watling Street,' which was printed in 1607, and has been absurdly attributed to Shakspeare. 4. 'The First Part of the Life of Sir John Oldcastle,' by Anthony Munday, Michael Drayton, Robert Wilson, and Richard Hathaway; published twice in 1601, one of the editions attributing it to Shakspeare. Munday died on the 10th of August, 1635, and was buried in the church of St. Stephen, Coleman-street.

MURAT. CAROLINA MARIA ANNUNZIATA BONAPARTE, sister of Napoleon, born at Ajaccio, in 1781, married in 1802 General Murat, then aide-de-camp to the Emperor Napoleon, and took the name of Bona Parte, afterwards Queen of Naples in 1808. She was the only sister of Napoleon who became a queen. She took a considerable part in the public affairs of the kingdom of Naples, and was frequently at court, and was often called upon to oblige to follow Napoleon in his never-ending wars. She displayed much ability, prudence, and firmness; she encouraged education and learning, and founded several useful institutions, among others one for the education of young ladies at Naples, which still remains. She had at various times a difficult task in acting as the part of a conciliator between her spirited but imprudent husband and her imperious brother. After seven years of reign, during which she showed herself worthy of the crown, she was obliged, through the reverses of her husband in 1815, to leave Naples on board of an English man-of-war, and to retire to Austria, where she lived for many years, and there died (March 21, 1824) in the house of the Count Cepli of Bologna. Madame Murat made a journey to Paris after 1830 for some family interests, and was well received by Louis-Philippe and his family. She afterwards went to Rome, and died there (November 15, 1854). Murat had a very favourable opinion of his sister Caroline.

(Lieu, Annivée.)

MURENA, an apodous sculp-tured fish of the family Muridae, and one of the large class of bony fishes. It is of the genus Helix. The operculum is large and oblong, one in each side. In each jaw there is a single row of teeth. The dorsal and anal fins are very long, and are united. The Murena Helena is one of the genus. It is found in the Mediterranean and Portuguese seas, and in one instance has been taken on the coasts of Britain. It grows to the length of between four and five feet, and even more. The body is smoothly, and boldly colored. The head is large and swollen, giving the fish a disagreeable aspect. It is excellent eating, and is highly esteemed by the ancients, who reckoned it among the best of fishes for the table, and kept the Murenae alive in vivaria.

MURPHY, ROBERT. No obituary has yet appeared, as far as we know, of this distinguished mathematician: and this, while we wish to remain with the interesting facts, and the talent alone, may justify us in giving the facts we have been able to collect at length. The materials for his early life have been communicated by J. Dillon Croker, Esq., of Mallow, one of his first pupils, and as the sheets for the pages of the corporation and companies of London. Ben Jonson, in 'The Case is Altered,' written early in 1599, ridicules him and his city-shows, in his character of Antonio Badalino, making this personage to say of himself, that he supplies the place of peasant-poet to the city of Milan when a worse cannot be had, and that he uses as much state stuff as any man does. Perhaps Ben's critical acumen was a little sharpened by the fact that Munday had just been called 'our best poet' in 'Meres' 'Paladins Tamia,' in which Jonson's own name is not mentioned. Mr. Collier enumerates fourteen plays which Munday wrote, and then adds, writing, desiring to be added to this list the recently discovered, and called 'The Two Italian Gentlemen,' which he attributes to Munday, and infers to have been acted about 1584. The following other plays of Munday are mentioned, viz.: 'The Death of Earl of Huntingdon,' by Anthony Munday; 'The Death of Robert Earl of Huntingdon,' by Anthony Munday and Henry Chettle, both acted in February, 1598, and printed in 1601. Both are reprinted in Mr. Collier's 'Supplementary Volume to Dodge's Old Plays.' They are rude and irregular pieces, possessing much vigour of painting, and presenting, in the scenes with Robin Hood's band in Sherwood Forest, some pleasing poetry. It, 'The Death of Charm,' acted in July, 1609; and supposed to be the comedy of 'The Puritan, or the Widow of Watling Street,' which was printed in 1607, and has been absurdly attributed to Shakspeare. 4. 'The First Part of the Life of Sir John Oldcastle,' by Anthony Munday, Michael Drayton, Robert Wilson, and Richard Hathaway; published twice in 1601, one of the editions attributing it to Shakspeare. Munday died on the 10th of August, 1635, and was buried in the church of St. Stephen, Coleman-street.

Robert Murphy was the third of the seven children of a shoemaker, parish clerk of Mallow in Ireland: he was born in 1606. His father intended to have brought him up to his own trade; but the son's destination was changed by an accident which nearly cost him his life. When eleven years of age, while playing in the streets of his native town, he was run over by a cart, and lay on his bed for twelve months with a fractured thigh-bone. From confinement, his family supplied him with such books and newspapers as they could procure; and among them there happened to be a Cork almanac, containing mathematical problems. These attracted the child's attention, and made him possessing Euclid and a work on algebra. The books were procured with some difficulty, and before he was again able to walk, and before he was twelve years of age, young Murphy was an extraordinary instance of a self-taught mathematician. A gentleman of the name of Mulcahy, of Cork, who was the tutor of most of those from the south of Ireland who got fellowships at Dublin Colleges, was in the habit of proposing problems (or cuts, as they are called in Cork) in the newspapers. At a certain time, he began to receive answers by return of post, from Mallow, without any signature. Surprised at the extraordinary talent displayed in these answers, Mr. Mulcahy went to Mallow to find out his unknown correspondent. After some difficulty, he found that the asserted author of the answers was a boy on crutches, so young that he could not believe the story. A few minutes' conversation, however, put it beyond a doubt. On coming away, in amazement, he happened to meet the gentleman to whom we are indebted for this account, to whom he said, with natural exasperation, 'Mr. Croker, you had a duplication of the cube, and it was done in Mallow: pray look after him.' It was then agreed that the boy should give up learning his father's trade, and pursue his studies. Mr. Hopely, who kept a classical school in Mallow, had the boy taken by him, took no charge of any kind; and he, in after life, had the satisfaction of transmitting to the widow of his teacher, then reduced to poverty, the sum which an ordinary pupil would have paid. When he attained the age of twenty, a certain amount of money was made to get him entered as a student of Trinity College, Dublin, but without success. The examinations for scholarships being classical, he had no chance: and some mathematical papers—which were sent to the authorities as the productions of a boy who had never had a teacher, and which, to judge by what we shall presently see, must have been of no common merit—received no attention. At this time Mr. Mackey, a Roman Catholic priest, published a duplication of the cube, the plausibility of which attracted attention, and, it is said, even obtained the assent of the teachers at Maynooth. Young Murphy, then eighteen years of age, answered this duplication in a pamphlet, entitled 'Refutation of the Claims of Father Mackey': the Rev. John Mackey, R. C. P. entitled 'A method of making a cube double of a cube, founded on the principle of elementary geometry,' wherein his principles are proved erroneous, and the solution not yet obtained; by Robert Murphy, Mallow, 1824' (20 pp.). The manner and style of this production are really extraordinary under the circumstances: with the exception of a little too much accuracy of expression, and a slight irregularity of style—nothing, which a critic would not find anything to attack in it, even as the work of an educated person of mature age. The young author had a confession in his style between Lord Brummaker and Dr. Brinkley, when he said: 'Dr. Brinkley told me, if he had seen it, he would have thought the circumference of a circle by a continued fraction.

The gentleman to whom we have several times referred now determined to try to get young Murphy sent to Cambridge. He applied to the clergyman of the boy

Vol. II. — X
with his Euclid and algebra. Mr. Brown, who was then em-
ployed in a bank of which Mr. McCarthy, a Cambridge
Master of Arts, was the proprietor. This last-named gentle-
man, being then about to visit England, promised to take
some of Murphy's papers with him, and to do what he could to
interest him in himself. (Professor Wilson, F. R. S.,
Vic., P. C.), to interest himself in the matter. The first answer
was not very encouraging. Mr. Woodhouse would say no
more than that if they would send the boy he would look
after him. On being requested to look over the papers,
he declined, saying, that he had no time, and made it a
rule not to do so. He desired that the papers might be
taken away, and on being requested to allow them to re-
maintain possession of their papers, he said that he was
able to deal with them, he predicted for them the fate of waste paper, and
the interview ended. In six weeks from that time, however,
Mr. Woodhouse wrote a hurried letter to Mr. McCarthy,
stating that at the moment when he was about to tear the
papers, in fulfilment of his prophecy, his attention was struck
by something that was almost new to him—that on turning
page after page, he saw with delight so much talent that he
was really unable to say how long he remained fixed to the
subject that he intended should occupy him but a moment—
that suddenly, recollecting it was the last day for entrance, he
hastily went and placed the name of the writer on the boards of
G. and G. he concluded by saying that Mr. Brown's friends would send him with fifty or sixty pounds in his pocket,
it would take care that they should not be called on again:
and this promise was faithfully kept. Mr. Croker immedi-
ately paid [....] pounds on Murphy's behalf, and Mr. Murphy began his residence at Caius College, in October, 1825. During his residence, the college supplied him with
money, in addition to the proceeds of his scholarship. In 1829
he took the degree of bachelor of arts, and came out third
 wrangler. The highest place is sometimes not to be gained by
any amount of genius and industry, unaccompanied by strict at-
tention to the University course of reading; and Mr. Murphy's
time was much occupied by a variety of studies, which did not
would not turn much account in an examination. In May,
1829, he was elected fellow of Caius; he shortly afterwards
took deacon's orders (he did not proceed farther), and was
made deacon of G. In the same year, he was made an actor
who, under the master, regulates the chapel discipline) in
October, 1831.
Of what he did in mathematics we shall presently speak;
we could wish there were nothing more to say of his private
life. He gradually fell into dissipated habits, and in December,
1832, left Cambridge, with his fellowship under sequestra-
tion for the benefit of his creditors. There is much excuse
for this. He was brought up in a very active and pushy
force of early talent into a situation in which ample com-
mand of money is accompanied by even more than proportion-
ate exposure to temptation. His college admitted the excuse to
life, and though it tolerated his prolonged residence of an officer who had shown such an example,
yet it was understood that his ultimate promotion to one of the more valuable fellowships would take place, on the amendment of his life. This college (G. in the same
year) in London, he came to London in 1836, to begin life again as a
teacher and writer. Among other things, he obtained from the
Useful Knowledge Society an engagement to write the
work on the Theory of Equations presently mentioned. In
October, 1838, he obtained a small permanent income by his
appointment to the examination in Mathematics and Natural Phil-
osophy in the University of London; but burdened as he was
with debts, this was only an addition to the instalments of his
credits, to an increase of his own means of comfort. He
submitted with resignation to the effects of his own miscon-
duct, and showed himself most willing to make every exertion,
though well knowing that many years must elapse before he
could, by any effort, redeem the ground he had lost. He
died March 12, 1848, of a disease of the lungs.
Mr. Murphy's writings were as follows:— Cambridge Phil-
osophical Transactions; vol. iii., part 3, General Properties
of Definite Integrals; vol. iv., part 1, On the Resolution of Al-
gebraic Equations; part 3, On the Inverse Method of Definite
Integrals, with Physical Applications; vol. v., part 1, On Elimi-
nation of Variables in Algebraic Equations of the Fourth
and Fifth Degrees; part 2, second memoir on the Inverse Method of Definite
Integrals; part 3, third memoir on the same; vol. vi., part 1,
On the Resolution of Equations in Finite Differences. Phi-
losophical Transactions; vol. i., part 1, Analysis of Algebraic
Equations; part 2, First Memoir on the Theory of Analytical
Operations. Separate works:—Elementary Principles of the
Theory of Equations; 8vo.; A Treatise on the Theory of
Algebraic Equations, London, 1833, 8vo.; On Electricity, Cambridge, 1833, 8vo.; (Library of Useful Knowledge): to these must be added some brief
articles on subjects of physics in the Penny Cyclopaedia,
beginning with the letter D.
Mr. Murphy's character as a mathematician is too well
known to require any comment of ours; while the facts of his
life, and in particular those of his removal to Cambridge, have
not been recorded: we have therefore preferred to devote our
space to the insertion of the latter. What he might have
been if the promise of his talents had not been dashed by the
unfortunate circumstances we have described, it is difficult
to say: for he had a true genius for mathematical invention.
Before however he had more than commenced his career, his
departure from Cambridge, and the necessity of struggling for
a livelihood, made it impossible for him to give his undivided
attention to researches which, above all others, demand both
peace of mind and undisturbed leisure.
MURRAY, LINDLEY, was born in 1745, at Swetara,
near Lancaster, in the state of Pennsylvania, North America.
His parents belonged to the Society of Friends, and he was
the eldest of twelve children. He received the rudiments of
education in the family besides the religious instruction in the
Society of Friends. In 1758, his father, who was an enterprising
merchant, removed with his family to New York, where Lindley
was sent to a good school. At an early age he was placed in
his father's business. After the latter's death, in 1767, the young
merchant profession, but having taken a decided dislike to it,
he prevailed on his father to allow him to have a private tutor
to instruct him in classical learning, and afterwards to place
him under an eminent lawyer, in order to receive instruction
in the law, to which profession he had resolved to devote him-
self. John Jay, afterwards governor of the state of New
York, was his fellow-student. About the age of twenty-one
he was called to the bar, and obtained a good practice he
soon afterwards married. He was sedulous in his applica-
tion to his business as a lawyer, and very successful till the
disputes commenced between Great Britain and America.
The law then ceased to be lucrative, and he entered into the
mercantile profession, with such success that about the time
of the establishment of American independence he had acquired
sufficient property to allow him to gratify his wish of retiring
from business.
Lindley Murray purchased a beautiful seat on the banks of
the river about three miles from New York, but before he
removed to it he had a severe attack of illness, which left him
in a very delicate state of body; the tone of his muscles
were so much impaired that he could walk but little, and his
debility continued to increase, in spite of change of scene,
bathing, and every other means of remedy to which he had
been subjected. In 1816, he removed to the country near
Davison, in New York, where he resided during the remainder of his
life. For a short time his muscular strength increased,
but afterwards diminished till he could no longer take exer-
cise except in a carriage, or in a vehicle in which he was
drawn about his garden, but for many years before his death
he was entirely confined to his room. In the sedentary state
to which he was reduced he occupied himself by reading and
the composition of works chiefly intended for the instruction of
youth.
Lindley Murray's first work, 'The Power of Religion on
the Mind,' was published anonymously in 1787. It is a
selection of passages from various authors, and was very
favourably received. The first edition of his 'English Gram-
mar' was brought out in 1796. A second edition was soon
required, and the book was revised and enlarged by the au-
thor, and then reprinted. 'Exercises,' to correspond with
the Grammar, and a 'Key' to the Exercises, were published
in 1797, in which year he also published an Abridgment of
the Grammar for the use of minor schools and those beginning
the study of the language. The work had a great sale
between him and each other; and were soon introduced into many schools.
The sale of them has been very large, and still continues
to be so. Murray's Grammar and Exercises however are
entitled to the highest praise; and he has been the last of the Rotten,
from which the materials have been arranged; they do not even approximate
The closest alliance of business and friendship long subsisted between Mr. Murray, and Constable of Edinburgh, and the Ballantynes; but he early perceived the result of the reckless mode of life which he conducted, and in foregoing the great advantages of the connection, after repeated and strong warnings and remonstrances, he separated from them. He published, however, 'The Tales of My Landlord,' and had no difficulty in discovering the real author of 'Waverley,' nor did he ever entertain any doubts on the subject.

In 1810 he sought and made the acquaintance of Lord Byron, giving 'Waverley' to the editor of 'Galignani's Harold,' which had been refused by another publisher. In 1812 he removed to Albermarle Street, where, increasing the number of his friends and literary connections, he soon surrounded himself with a circle of literary characters. In the afternoon might be found in his drawing-room, Scott, Byron, Campbell, W. Spencer, R. Heber, Gifford, D'Israeli, Mr. Ward (Lord Duddly), Canning, Hallam, Croker, Barrow, Madame de Staél, and, a few years later, Crabbe, Southey, Belzoni, Washington Irving, Lockhart, and many more.

His acquaintance with Byron extended over a period of more than ten years, and the poet's correspondence with him is printed in Moore's Life of Byron, where will be found more than one proof of his liberal mind. Having heard in 1815 that Lord Byron was in pecuniary difficulties, he sent him a draft for 1000 guineas. It was received at the course of a few months, and offering to sell the copyright of Byron's works for his use, if that were not sufficient. He abandoned the publication of Lord Byron's Autobiography, at a considerable profit, he being it was said, persuaded that it of it might hurt the feelings of the living, and do not credit to the dead. The MS. and the only existing copy of it were consequently committed to the flames in 1824. Soon after Mr. Murray commenced printing a series of 'Modern Voyages,' parts, consisting of 'Modern Voyages,' the publication of which was delayed by circumstances—a specimen however given by him to Captain Basil Hall was taken to Edinburgh, and suggestions suggested the possibility of being printed in the 'Scotsman.' In 1826, trusting to others more sanguine than himself, and allowing his own good judgment, perhaps, to be misled by partiality for the projector, he commenced 'The Representative,' a daily newspaper—almost the sole undertaking of his life which proved a failure. It was attended with considerable loss, which fell entirely on him, and was soon given up. Among his valuable and successful publications were the expeditions of Munro Park, Belzoni, Perry, Franklin, Denham, and Clapperton—the Family Library, begun April, 1829—the Domestic Cookery, of which nearly 300,000 copies have been sold, the fortunate title having been suggested by the 'Ladies' Manual.'

Further part of his life was passed as a general bookbinder, in partnership with Mr. Highley, but having dissolved the partnership in 1850, he soon devoted his attention to a wider field of literary business. The son of an old friend and neighbour, Dr. Bennell, Master of the Temple, Mr. Stratford Canning, with some other youths at Eton, had commenced a periodical called 'The Miniature,' which brought them some fame, but left them under loss. Mr. Murray, with a good nature which always distinguished him, and with something of that tact which enabled him, in his subsequent career, to seize upon occasions of cultivating powerful friends, on hearing of their situation took the copies off their hands, paid their expenses, and though he found little demand for the work, offered to print a new edition. Through the friends thus made, he became known to Mr. Canning. In September, 1807, he wrote to that gentleman opening to him the plan of the 'Quarterly Review,' as a means of counteracting the political influence of the 'Edinburgh Review.'

While maturing his project—the most important undertaking of his life—it chanced that a severe criticism of Scott's 'Marion' (1820) appeared in the 'Edinburgh Review.' Mr. Murray instantly started for Scotland, was introduced to Scott at Ashieethe, in September, 1828, found in him a warm supporter of his intended review, and subsequently the idle speculations of Mr. Murray. Hebers, George Ellis, Canning, Barrow, and Mr. Gifford, the editor, the publication commenced in 1809, and soon attained a circulation of 12,000 copies.
effort by dealing honourably and generously with authors whose reputation was established, or of whose success there could be no doubt, was not as unfortunate as the equitable distribution of the rewards of the capitalist and the labourer. He was distinguished too, by his careful avoidance of the low arts of puffing; he published, for the most part, books of worth, and his impartial alone gave a recommendation to a science which raised it above the necessity of advertising quackery. Mr. Murray continued to take an active share in his business until within a short time of his death. Although his health had been in precarious state for some months preceding it, no danger was apprehended until two or three days before this occurred. Mr. Murray married in 1807 the daughter of Charles Eliot, bookseller, of Edinburgh, by whom he left one son, who continues his business, and three daughters.

MUSCA, a genus founded by Linnaeus for the reception of the Dipterous insects, commonly known as Flies. The Linnaean genus has been broken up by subsequent entomologists into many genera and even families. Of the typically Muscidae no fewer than 1700 European species have been described by Meigen, and nearly as many more extra-European have been described by Robineau Desvouz in a quarto volume of 912 pages, devoted entirely to this subject.

Many of the Muscidae are interesting on account of their habits. Some of the species of Myobia deposit their eggs in the nests of Hymenoptera, so that their larvae when hatched are placed in the middle of the nest where they feed on the larvae of the Hymenoptera. The larvae of Tachina are parasitic on other larvae. Those of some other genera are only found in the dead bodies of particular species of animals, as Cynomya, which resides in the cavity of the brain of wild-boars, and blow-flies of species of Lucilia and Calliphora, lay their eggs in meat, which becomes fly-bitten. Anthomyia deposits its eggs in manure or in the roots of vegetables, and Tephritis in growing plants. The adult male of the larva of this family named Piophila casei. Dryophila collaris deposits its eggs in fermented liquors.

Most of these flies are extremely prolific; the ovaries of the female, according to Megas, contain eggs that have been found to be arranged in spiral fashion and to contain as many as 20,000 eggs.

(Westwood, Introduction to the modern Classification of Insects and the writings of Meigen, Haliday, Desvouz, and Macquart.)

MUSCA/R/1, a genus of plants belonging to the natural order Liliaceae. It has a globose or subglobose perianth narrowed at the mouth and 6-toothed. The stamens are inserted at about the middle of the tube, the filaments not recurved. R. racemosus, Grape Hyacinth, is the only British species of the genus; it is found in Scotland near Perth, and is found in some other parts of Great Britain. It has ovate nodding crowded flowers, the upper ones nearly sessile, abortive; the leaves linear, falcate, and recurved. The flowers are often heard in the garden at this time of year. The bulbs of Muscari are, according to Lindley, emetic.

(Bulbring, Manual of British Botany; Lindley, Vegetable Kingdom.)

MUSCOVADO SUGAR. [SUGAR, P.C.]

MUSCULAR TISSUE. [TISSUES, ANIMAL, P.C.S.]

MUSEUM OF ECONOMIC GEOLOGY. This institution owes its origin to the suggestions of Sir H. T. De la Beche, who, in 1835 submitted to the Chancellor of the Exchequer, that the persons employed in the Ordnance Geological Survey had constant opportunities afforded them of collecting specimens illustrative of the application of geology to the useful purposes of life, and of the mineral wealth of the kingdom. The advantages which would arise from such a collection, and its exhibition to the public, under the care of the Board of Public Works, were briefly pointed out. The Museum now occupies the houses Nos. 5 and 6, Craig's Court, Charing-Cross, the former containing the Mining Record Office; and the latter the specimens; the establishment is open to the public, between the hours of ten in the morning and four in summer, and ten and five in winter. The principal officers to the establishment are Sir H. T. De la Beche, already named as the Director, Mr. Richard Phillips, Curator, who is also the Librarian of the Museum; Wm. Voda Dr. Lloyd; Playfair; Mr. Robert Hunt is keeper of the Mining Records.

The objects contemplated in the arrangements which have been effected were—to obtain specimens of the various mineral substances used for the construction of public works or buildings, or for road-making; of such as are employed for useful or ornamental purposes in the arts, or from which the useful or ornamental products being arranged with reference to the instructions of those to whom such knowledge would be advantageous, either in a scientific or practical point of view.

With respect to building-stones it may be observed in illustration of the utility of the establishment, that there exists in it a collection, described by appended tickets, of the various specimens of building-stone, procured by the Commissioners appointed in 1836 to visit the quarries and to ascertain the qualities of the stone to be used in building the New House of Parliament. These specimens, with the elaborate report in which their properties are described, cannot fail to be a source of great and lasting utility to the architect who seeks for information.

In addition to these specimens there are also exhibited numerous polished granites, porphyries, and marbles from various parts of the kingdom; some of the specimens are turned into columns, and others turned and vases.

Another object intended to be effected by the formation of the Museum is the promotion of improvements in agriculture, by exhibiting specimens of strata, with specimens of soil, subsoils, and the rocks from the decomposition or disintegration of which they have been produced. It is intended, by this department of the Museum particularly, to exhibit the relations of geology to agriculture by imparting such a knowledge of the mineral riches of any extensive tract of country, that the Director has been especially careful in collecting specimens of the coal from every part of the British kingdom, and the public have liberally contributed to this and indeed to every part of the institution.

An annual grant is voted by Parliament for geological sections of railway cuttings, a service of much importance, especially in the mineral districts.

The Museum contains an extensive collection of the various metalliferous ores of Great Britain, with specimens of the results of the metallurgical processes by which the metal is extracted, accompanied with illustrations of many of the purposes to which the metals are applied.

The application of various earths and metallic oxides to enamelling, and the manufacture of glass and of porcelain, is illustrated by specimens of the art of different ages.

It is to be further observed that a laboratory forms another department of the Museum, in which the application of minerals is performed for the public on very moderate terms, and pupils are admitted into the laboratory for instruction in analytical and metallurgical chemistry.

In the museum of the present department are deposited plans and sections, and models of mines, and of the machinery by which they are worked; it also contains workshops in which many of the models have been constructed; and collections of mining tools and instruments are now in daily use.

The department having for its objects matters which concern particular parties, rather than the public generally, is, from the nature of its contents, not open to indiscriminate admission, but every reasonable facility is afforded to all operative miners as well as the owners or agents of mineral properties, by application to Mr. R. Hunt.

In concluding this brief sketch of the Museum, we may observe that, owing to the great liberality with which it has been supported by the government and by the public, it has been for some time past impossible to exhibit the accumulated specimens for want of room. It is understood that, on this account, Government is building a large and more commodious house for the purpose, which will extend from Piccadilly through to Jermyn-street.

MUSKROOM. [Agaricus, P.C.]

MUSKA, a genus of fossil plants, the fruits only known. From the coal measures of Lancashire. (Bronnmlart.)

MUSCOWA, or MASSOWA. [Anthemia, P.C.S., p. 24.]

MUTILLIDÆ, a family of Hymenopterous insects corresponding to the Linnaean genus Mutilla. These bees belong to Latreille's family Apidae; all of the species are remarkable for the power of their stings.

MUZIA'NO, GIROLAMO, an eminent Italian painter, was born at Acquafreda near Brescia, in 1528. He was first instructed by G. Romanino at Brescia; he then turned his
attention to the colouring of Titian, and particularly to his landscape backgrounds. About 1550 he went to Rome, where he first attracted notice as a landscape-painter, and he was known as 'the great landscape painter' by the Italian critics. He was known as ‘the landscape Jerome.’ He however soon showed that he was equally capable not only in all departments of painting, but in other kindred arts likewise; and he became one of the first painters of his time, and even in the characteristic grand style of the Roman school he obtained a place in the ranks of the greatest masters. Michelangelo himself pronounced Muziano to be one of the first painters of the age, when he saw his large picture of the Assumption of the Virgin, which he painted for the church of Santa Maria Maggiore. This picture was afterwards removed to the Armeno de’ Principi in the Quirinal, or papal palace of Monte Cavallo, where it was preserved, although destroyed, in 1768, but it was not seen there by Ramondi a few years afterwards. There was a Resurrection of Lazarus by Muziano in the Orleans Gallery at Paris, but as this piece was engraved by S. Vallois for the ‘Cabinet de Crozat,’ in 1729, as a part of the Orleans collection, it cannot be the picture so much approved of by Michelangelo, unless the account of Titii is incorrect. When the part of the Orleans collection, of which it was one, was sold by auction in London in 1806, it fetched only fifty-six guineas: who the purchaser was, or where it is now, is not publicly known.

There are many of Muziano’s works in the private collections and palaces of Italy, and his works are to be found in the various churches and the cathedrals of Orio and Foligno, in the church of the Madonna at Loreto. There is likewise a very celebrated picture by him of Christ washing the feet of his disciples, in a church in the same city, which has been engraved by L. Deplasni. Muziano painted many historical landscapes, or landscapes with historical personages or events so introduced into them as to be secondary objects, and of which scenes he was the occasion for a title to the landscape. Several of these pictures have been engraved by C. Cort, who executed also some prints after other works by Muziano.

The Roman mosaics-executed in this style. He performed great services in the art of working in mosaic: what was merely a crude and ornamental art of inlaying coloured stones, he brought almost to the perfection of painting. As an architect, he built the Capella Gregoriana, or the chapel of Gregory XIII. in St. Peter’s, in which are two of his best pictures, which however he did not live to complete; they were finished by his most distinguished scholar Cosme Nebbia, a painter of Orio. Muziano also completed the series of drawings which Giulio Romano had commenced from the sculptures of the Colonna Trajana at Rome, and the first plates of which were engraved from these grounds, or the prints of Bartoli were engraved from drawings by himself. The foundation of the Academy of St. Luke at Rome is also due chiefly to the exertions of Muziano: he procured the building for it, and it is now open to Gregory XIII., and it was confirmed by Sixtus V.

Muziano died at Rome in 1590, according to Baglione (Ridolfi says 1592), and was buried in the church of Santa Maria Maggiore, near the spot where his picture of the Resurrection of Lazarus was placed. His style was severe, and more than ordinarily correct for his time, though he may be reckoned among the imitators of Michelangelo, whose anatomical display seems to have had its due share of influence, on the taste of Muziano. Many of Muziano’s works have been engraved by some of the best engravers of the seventeenth and eighteenth centuries, and by his contemporaries, Ch. Albani and C. A. Ascani.

(Muguale, a species of spiders, the species of which have their eyes placed closely together at the anterior extremity of the thorax. They spin their webs in the form of tubes, in which they are concealed. They travel under stones, or the bark of trees. In consequence of the representations of Madame Merian, some kinds of Mygale have become celebrated as butterflies; and even spiders! Mr. St. Helier has however shown that Madame Merian’s drawing is not to be trusted, since the Mygale there figured is a supernumerary spider, and makes no net in which to entrap small birds. The same distinguished naturalist has observed a spider belonging to the genus Epeira: eating a young bird of the genus Zosterops, which had been entangled in its net in a garden in Sydney, New Holland. In a communication of Mr. Macleay to the Philosophical Transactions in 1822, he says, History for 1842, he remarks on the subject of bird-catching spiders as follows:—‘My conviction is that Madame Merian has told a wilful falsehood respecting Mygale, or rather has painted a falsehood respecting Lycophora, which I have proved to the genus Nephila, which lives in a geometrical net, does not catch birds either here or in the West Indies; and moreover, I have ascertained that birds are not the proper food of this New Holland spider.’ The Mygale Iodice, a Grecian species, forms a very ingenious trap-door with which to close up the mouth of its tube. MYOSUROS (from μυς, a mouse, and σως, a tail, the seeds being seated on a long receptacle ‘which looks exactly like the tail of a mouse’), a genus of plants belonging to the natural order Ranunculaceae. It has a calyx of 5 sepals, prolonged into a spine at the base; the petals 5, with a filiform tubular claw; the ovary deeply imbricated upon a very long receptacle, numerous carpels, and linear leaves. It grows in damp places in fields. It is a native of Europe and America. The American plant has been described as M. S. Smith, but I doubt whether I should believe it is the same as the British and other European plants.

(Begonia, Monon.)

MYOSTOBitus (from μυς, a mouse, and ὀνος, the erume form of ος, an ear), is a genus of plants belonging to the natural order Boraginaceae. It has a 5-parted calyx, the corolla salver-shaped, contorted in stivation; the throat closed with scales, the limb 5-fid, obtuse; the stamens included, with filaments very short; the style and the nectary, externally con- vex, keeled within, attached by a minute lateral spot near their base. This genus is distinguished from all the other Boragi- neae genera, by the possession of a contorted stivation of the corolla. The species are annual or perennial, rough or smoothish plants, with blue flowers in terminal racemes, which are revolute before expansion. About fifty species have been described, which inhabit the more temperate parts of Asia, Africa, and America, and are found abundant in Europe. Eight species are found in Great Britain.

M. palustris, Great Water Scorpion-Grass, or Forget-me-Not, has the calyx open when in fruit, and shorter than the perianth, the calyx-lobes divided, with strigose-bristled, con- cava, the limb of the corolla flat, longer than the tube, the lobes slightly emarginate, the subgenus of the stem spreading. It is a native throughout Europe, and also of Asia and North America. In Great Britain it is found in wet meadows, bogs, banks of rivers, rivulets, and ditches. This plant has a large bright blue corolla with a yellow eye. It is a beautiful plant, and when once seen will be seldom forgotten. It is probably on this account that it has obtained its common name Forget-me-Not. Amongst the young it is regarded as emblematical of true affection. A variety is described with white flowers.

The following are the remaining British species of this genus:—

M. repensa, Mouse Ear, with narrow lanceolate teeth; lobes of the corolla slightly emarginate, the subgenus of the stem spreading. Found in dry places.

M. coerulea, with narrow lanceolate teeth; the limb of the corolla equaling the tube, the lobes entire, the subgenus of the stem adpressed. Found in water places.

M. scorpioides has an attenuate limb of the corolla longer than the tube, the root-leaves on long stalks pointed. Only found in Scotland on the summits of the Breidablik mountains.

M. alyssoides has a calyx rounded below, deeply 5-cleft, closed when in fruit; the limb of the corolla longer than the tube, flat; the root-leaves blurnish. Found in shady places.

M. alyssoides, with the calyx-lobes of calyx, has the calyx half 5- cleft; the limb of the corolla longer than the tube, concave. Grows in cultivated land and thickets.

M. collina has the calyx open and ventricose when in fruit. Found on dry bank.
M. varicolor has the calyx closed and oblong when in fruit. It has small flowers, at first pale yellow, afterwards red. It is found in meadows and on banks.

None of the British genera is the size of the myrtles or the arts. The British species are most desirable for cultivation, especially M. palustris and repens. All the perennial species require moist situations, as the edges of ponds or ditches. Some of the species may be grown in pots among other alpine plants. The annual species will grow in a dry sandy soil or on old walls, where the seeds may be sown. The other species may be propagated by dividing the roots.

(Myrtaceae; Manual of British Flora; Don, Gardener's Dictionary.)

MYRICA, a genus of fossil fishes, from the beds of Domanian (Agassiz). MYRANTHES, a genus of fossil Annelsida, from the lower silurian strata of Lamberth, in South Wales. (Murchison.)

MYRIA (the Greek unnamed), a genus of plants the type of the natural order Myricaceae. It has its flowers in catkins, which are composed of concave scales; 4 to 8 stamens. The fruit a 1-celled 1-seeded drupe, and no perianth. There are several species of this genus, which are shrubs or small trees.

One species, M. Gale, the sweet Gale or Box Myrtle, is a native of Great Britain. It has lanceolate serrate leaves broader upwards, with a shaggy stem. It is a bushy plant, and the catkins are sessile and erect; the fruit is covered with red or yellow glands, and the leaves are fragrant when bruised. This plant is found on the Continent of Europe, and also in North America, under the same circumstances. The leaves are divided into catkins, leaving a yellow stellate oil, of a fleshy odour, and mild taste, which after a little time becomes slightly warm. The seeds were formerly used as a remedy against the itch, and when bruised are used amongst fires for the destruction of the moth. In decoction they are employed for the destruction of bugs and other vermin. In Sweden they are used as a substitute for hops in brewing.

Wax-myrtle or Bay-tree, has cuneate lanceolate leaves, sometimes entire, but more frequently toothed, particularly toward the end, somewhat pubescent, a little paler beneath, and generally twisted or revolute in their mode of growth; has a branching half evergreen stem, from one to twelve feet high. The small flower is formed by a concave rhomboidal scale, containing 3 or 4 pairs of roundish anthers, on a branched footstalk. The pistilliferous catkins which grow on a different shrub are less than half the size of the staminiferous ones, and consist of narrower scales, with each an ovate ovary, and two filiform styles. To these catkins succeed clusters or aggregations of small globular fruits, which are at first green, but finally become white or yellow. They are covered with a hard sheathing covering, which incloses a dicotyledonous seed. The hard covering is studded on its outside with small black grains, and over these is a coating of hard white wax, fitted to the grains, and the whole sheathing covering of the fruit of the wax-myrtle. This plant is a native of woods in the United States of America. The bark of the root of this plant is acid and astringent; in large doses it produces vomiting, accompanied by a burning sensation in the throat. It is used as a stimulant and astringent. The wax of the fruit is collected and purified, and used for many of the purposes for which bees-wax and candles are employed. The wax has been occasionally used in pharmacy in the same way as common bees-wax.

The fruit of M. sappida, a native of Nepal, is about the size of a cherry, and is pleasantly acid and eatable.

(Lindley, Flora Medicia; Lindley, Vegetable Kingdom; Babington, Manual of British Flora.)

MYRIOPHYLLETS, a genus of fossil plants, from the coal measures. (Arnis.)

MYRIOPHYLLUM (from myro, numerous, and phyllon, a leaf), a genus of plants belonging to the natural order Halaeraceae. It has monoeccious flowers; a 4-parted calyx; 4 petals fugitive, longer than the calyx in the staminiferous flowers, small and reflex, or none in the pistilliferous flowers; style a little style, villous and separable into 4 hard nuts. The species are floating aquatic herbs, rising above the water to blossom. The leaves are finely cut opposite or verticillate; the flowers are small, disposed in spikes or in whorled spikes, the upper leaves being almost abortive. M. verticillatum, verticillate water milfoil, has the flowers all axillary whorled, the bracts pinnatifid. It is a native of Europe, in ponds, ditches, pools, and lakes, but never in running water. It is found in Great Britain, but is a rare plant, M. spicatum, spiked water milfoil, has the flowers whorled, forming a spikelike whorl, the bracts pinnatifid and spike erect when in bud. It is a native of Europe and North America, in ditches, lakes, and pools, never in running water; it is found abundantly in Great Britain.

M. alterniflorus is, that in the drooping when in bud, and the fertile flowers in axillary whorls. It is found in ponds and ditches in Europe, in Great Britain rarely. A bout ten other species of this genus from various parts of the world have been described. They are found employed in medicine and the arts, and they are only worth cultivating in botanical gardens. When it is wished to grow the tropical species, G. Don recommends that small parts should be taken up in April or May, planted in the drooping when in bud, and be placed in the stove in order to preserve them in a living state during the winter, and in the course of the April or May next season, may again be returned to the pond in the same air, where they will thrive much better than if grown all the year round in pans of water or cisterns in a hot-house.

(Adams, Gardener's Dictionary; Babington, Manual of British Flora.)

MYRIRISTIS, a genus established by Cuvier for certain tropical fishes of the family of Perches. MYRIPLEON, a genus of large neotropical insects, of which the larvea are very distinct and exhibit a habit of entrap ing their prey by means of pitfalls. Among the many accounts which have been published of their operations, one of the best and most recent is that given by Mr. Westwood, in the Myripleon formiculaceus, is written that naturalist, with which I brought alive to this country from France, afforded me ample opportunities for watching its habits and modes of life, and the following forms are given to the genus and illustrated in the introduction. 'Some larve of the common species, Myr ripleon formiculaceus, writes that naturalist, with which I brought alive to this country from France, afforded me ample opportunities for watching its habits and modes of life, and the following forms are given to the genus and illustrated in the introduction."

Exsquitum post tergum magnum faciat parentis.

Precipitating in this manner, in a spiral direction, it gradually diminishes the diameter of its path, and by degrees throws so much of the sand away as to form a conical pit, at the bottom of which it then conceals itself, its mandibles widely extended being the only parts that appear above the surface; with these mandibles it deftly opens the mouth of the hole, the hole is immediately seized and killed. When the fluids of the victim are exhausted the ant-lion, by a sudden jerk, throws the dry carcass out of the hole; should, however, the insect by any chance fall down the hole, the latter immediately commences throwing up the sand, whereby not only is the hole made deeper, and its sides steeper, but the escaping insect is probably hit, and again brought down to the bottom of the pit. It is chiefly upon ants and other soft bodied insects these larve feed. They are however capable of undergoing long fasts, for one of my larve reared from October till March without food. Previous to assuming the pupal state, the larve forms a globular cocon of less than half an inch in diameter of fine sand, glued with silken threads spun from a slender telescop-like spinneret, placed at the extremity of its body, and lined with fine silk. The pupa is small, not being fifteen inches long, inactive, and with all the limbs laid at rest upon the breast. When ready to assume the perfect state, it uses its own mandibles, which are quite unlike those of the larve and image, to gnaw a hole through the cocoon, and pushes itself partly through the aperture in which it leaves the pupa skin. Immediately on assuming the perfect state, the abdomen is almost immediately extended to nearly three times its previous length. (See also the writings of Rosell, Reemur, and Bonnet and Guiding.)

MYRON, one of the most celebrated artists of ancient Greece, as the sculptor of the Discobolus, or Quoit thrower, of which that among the Towneley Marbles in the British Museum is supposed to be an antient marble copy, was born at Eleuthera in Boeotia about 480 B.C. Myron was the fellow-
pupil of Polyceuts under Ageleides; he was therefore in the prime of life at about the time that Phidias died; and he lived at the height of his fame in Athens, where he was domiciled, at the commencement of the Peloponnesian war.

Myron's fame rests upon his first obtained reputation by a brazen heifer, much celebrated by the poets, which gives Pliny occasion to reflect that men derive more good from the wit of others than from their own. He mentions a bronze of a discus-thrower; Persians have him to thank for a metope, and, as Böttiger explains pristis, sea-monsters; also a satyr admiring a flute; Minersa; Delphic pentathletes; pancra-
tiasts; a Hercules which was in the temple of Pompeius in the Circus Maximus. Also a statue of Mars; Myron also seems to have been restored to the Ephesians, being warned to do so in a dream.

Myron is said to be the first who represented in sculpture Nature in her multiplicity of forms: he represented man and animal with equal success; he almost, says Petronius (Satyr. c. 88), gave the souls of men and animals to brass. He was, says Pliny, more numerous and various than Polyceuts, but was not so exact in his proportions: he was curious in all corporeal detail, but paid little regard to expression: whether Pliny means this or not by the words 'ipse tamen corporum tenus curiosus, anima sensim non expressae,' it is one of these terebrats which would very well distinguish the vieing sculptor who was excellent in representing animals, a quality indicating a strong love of the variety of forms. Myron seems to have adhered in the head and face to the earlier types of rendering: without any particular feature in the formal manner of the earlier artists, which he much more probably did from taste than from any want of perception, as Pliny seems to imply.

At an observation of Pliny's, Winckelmann placed Myron back to the time of Anacreon and Eriina: Pliny supposed that an epigram of Eriina spoke of a monument to a grasshopper and a locust by Myron; this epigram is in the Greek Anthology, and is ascribed to Anyte, but the Myron, not Myron, there spoken of, says Sillis, is a virgin whose charms were sometimes fatal to her rivals. Myron executed many works consecrated to the gods, a number of which were preserved at Rome. Augustus placed four oxen in the portico of the temple of Apollo on the Palatine Mount, and a statue of Hercules is mentioned by Cicero as one of the works plundered by Verres. A statue of Apollo also, with the statue of Myron on the thigh in silver letters, was plundered by Verres from the temple of Bacchus at Agrigentum, where it had been consecrated by Publius Seipio: Pausanias mentions the Perseus killing Medusa. A great work by Myron was a group in the Heraeum at Samos, of Jupiter with Minerva and Her-
cules, one on each side, of which the figures were colossal: it was removed to Rome by M. Antonius, but the Minerva and Hercules were restored, turned his statue over, he added a statue of Jupiter he placed in the Capitol. A Bacchus is mentioned by Pausanias, which, he says, after his Eroctheus, was Myron's best work at Athens. The Athletes by Myron must have been very much admired, according to the pieces of inscriptions which describe them; this class, there is mention of several in Pausanias and other antient authors: as Ladas, a celebrated Lacedaemonian runner; two of Lycurus, a Lacedaemonian charioteer, at Olympia; Timanthes of Cleonos, a pentathlet, Philippon of Paleone, a juvenile pugilist; and one supposed to be Chloris of Lace-
daemon, also an Olympic victor, but denied by Pausanias to be Chloris (vi. 13).

All the above works were executed in bronze of Delos. Polyceuts used the Eginia bronze. But Myron was also a sculptor in marble, a carver in wood, and an engraver of metals. Pliny mentions a celebrated marble statue of a drunken old man, by Myron, which not being approved by Pausanias describes it by him a single-bodied Hecate with one head, in wood, which he saw on the island of Eginia: she was the chief divinity of the Eginetans according to Pausanias (ii. 90).

The discobolus, the son of Eileithys, was his Cow, lowing, and according to some sucking a calf; there are no less than thirty-six epigrams on this work in the Greek Anthology. No human figure has attracted so much notice, and diffuses so much celebrity, as a discobolus; Pausanias describes it as the most noble form, and as of a small size, and, however excellent, would have little effect compared with an isolated bronze, perhaps gilt, figure of the natural size, and fixed upon a marble pedestal in the centre of a public place. So according to Cicero it still stood in his time, though it was removed before Pausanias visited Athens, for he did not see it: in the time of Priscus it was in the temple of Peace at Rome. Ausonius wrote the following beautiful epigram on this work:

Bucullum sum, acelo gentioris fatus Myronis; nemo / acu factum me pote, sed gentilam. Signavit ictum; sine proximo magti; / Sic victor est ara, ubi mores prist. Mensas circumscribere cupit magister / Inter pascam te numine silet.

(Epigr. 56.)

The same idea is still more happily expressed in an old Greek epigram, inaccurately attributed to Anacreon; the following English version of it is from an old translation of Anacreon printed by Sir J. Curl, and is attributed to Fawkes:

This heifer is not, but rolling years / Harden the life to what it now appears. / Nature unjustly would the honour claim / But Nature has prevented him in fame.

Sonntag has collected all the numerous epigrams on this work of art. The Discobolus by Myron was one of the most celebrated works of antient art: the original was in bronze, but there are still several ancient copies of it in marble, though not one entire: one in the Campidoglio, one in the Vatican, and a third was in the Villa Massimi at Rome; that in the British Museum was found in the house of Hadrian near Temple, in 1791, and passed into the possession of Mr. Townley through the hands of Mr. Jenkins, a well-known dealer in works of art of that time. Some other trunks of antient statues, which have been very much restored, have been ascribed to Myron, and are of importance.

The Discobolus of Myron the head is noticed as being turned and looking back, as it does in some other of the reputed copies of this celebrated work. It must be observed however that there is no proof whatever that any of these marbles are copied from the celebrated Discobolus of Myron. The statue of Fea appears to have been the first to suggest the identity, which occurred to him from the similarity between the Massimi Discobolus and the Villa Palatina statue, both in 1782, and a Discobolus by Myron as described by Lucian and in part by Quintilian. Quintilian (ii. 13) merely alludes to its distorted position and elaborate execution; Lucian (Philoseudes 18) describes it more in detail; he says—'The Discobolus, in the twisted posture with the hand reversed and one knee bent, as if about to vary his attitude and rise with his throw, his head being turned to the right and the left, the boy holds the quoit;—the quoit-bearer,' which Fea interprets 'by the hand in which he has the quoit.' These words are however sometimes rendered 'the boy or girl who holds the quoit;' implying that the thrower was not yet in action, having only assumed his position. The quoit is also extended from the right to the left hand of the boy, as Fea from the bearer in attendance, who is implied only by the attitude of the Discobolus, not expressed. The Townley marble is however throwing the quoit, both knees are bent, and the quoit is held on the right. The quoit-bearer, as the Attic copies, are turned back: the action is perfectly momentary, and he is already giving the impetus to his throw. Barry preferred the forward direction of the head, as in this statue, to the turn spoken of by Lucian and seen in other statues of this subject, as much more consistent with the necessary impetus of the throw: he says—'The position of the head, hanging down in the same direction as the body, is very remarkable in Mr. Townley's figure, as it is a deviation from the original of Myron, as described by Lucian, and consequently from the Massimi copy, which corresponds perfectly with that description. In all other respects these figures agree, and this deviation appears to have been made, as in this way all ambiguity in the intention of the figure, by the direction of the eyes (which are not wanting in the action), is ingeniously avoided; and in finishing the action, at least an equal acceleration is produced by the head shooting upwards and forward, along with the other extremities.'

Myron had a son Lycius who was likewise a sculptor. He is mentioned by Pliny, and Pausanias (i. 28) says he saw in the city of Phigaelia a bronze by Myron, which he said was made by Lycius the son of Myron (Kühn and Ammianus read Anaxo in this passage): Pliny calls Lycius the pupil of Myron.

sichem und Geschichte der Plastik bei den Griechen, in his
Andeutungen zu Vorträgen über die Architektur; Göthe, Preussische Akademie, vol. i. See also Speccimen of am-
tienti Sculpture, published by the Society of Dibertii, vol. i.,
and vol. i. of The Townley Gallery of the Society for the
Diffusion of Useful Knowledge, in both of which the Diace-
bole of Thisbe can be seen.

MYRRH, a genus of plants belonging to the natural
order Umbelliferae, and to the tribe Scandiceae. It has
an obsolete calyx; obcordate petals, with an infixed point;
the fruit not beaked, the capsule covered with a double membrane;
the outer membrane with elevated keeled ridges hollow within,
the inner one close to the seed; no spines. The species have
leaves three times decomposed, the leaflets pinnatifid;
the involucral bracts lanceolate cym-
ated leaves, the central flowers of the umbel stamini
fere; the petals white.

*M. odorata*, Sweet Cicerel, or Great Chervil, has the
leaves downy beneath, the leaflets of the partial involucres
lanceolate acuminate. This plant has a stem 2 or 3 feet high,
round, leafy, and hollow. It is native of Middle and South
Europe and Asia, from Spain to Asia Minor, also of Germany,
Switzerland, Austria, the South of France, and the North of
Italy. In Great Britain it is found in pastures and hilly
districts. This plant was formerly much used in medicine.
It yields a volatile oil, which has a pleasant odour. The young
leaves were frequently used in salads. The roots were
boiled or eaten cold, or in tarts or in a variety of sauces.
In Germany the seeds were added to soups, and in the North
of England they are employed for polishing and perfuming old
oak floors. The flowers are white, the involucral bracts
acuminate, and the seed is a native of Spain. Both species may be grown in
any common garden soil, and propagated by seeds or division of
the roots.

(Myrtus, Manual of British Botany; Burnett, Outlines of
Botany.)

MYRTUS (Greek, μύρρος), a genus of plants, the type
of the natural order Myrtaceae. It has the calyx-tube somewhat
globular, the limb 5- or very rarely 4-partite; the petals
5, or very rarely 4; the stamens distinct; the berry 2- or 3-
celled, somewhat globose, crowned with the segments of
the calyx; several seeds in each cell, or very rarely solitary;
uniform, with a bony testa; the embryo curved, coryledons
semicilindrical, very short, the radicle twice the length of
the cotyledons. The species are shrubs with opposite quite
entire pellucid-dotted leaves; peduncles axillary 1- or rarely
3-flowered.

*M. communis*, Common Myrtle, has solitary 1-flowered
pedicels about the length of the leaves, bearing 2 linear
bracteoles under the flowers; the calyx 5-toothed; the leaves
ovate to orbicular. This bears the name of a native of the
south of Europe; it is found wild in France about Mar-
selles, and extends from that city along the sea-coast to
Génes, and throughout Italy. In these districts its fruit is
tasted by the natives. The berries grow without the shrubs of the
sea. This plant has been in all ages a great favourite in
Europe. It was called by the Greeks μύρρος. Μυρίγνιον is
the name under which Hippocrates refers to this plant
(Marc. Milt. i. 598). Theophrastus also uses this word and
μυρίγνιον and μυρίς, in speaking of the myrtle.
The Romans knew this plant by the name of *Myrtus* (Plin.
12-13). This name has been adopted in most European
languages: it is *Mirta* in Italian and Spanish; *Murre* in German;
*Müter* in Danish; *Myrten* in Swedish; *Mirte* in
French; *Murta* in Portuguese.

The leaves of the myrtle, like the whole order, contain
a volatile oil which possesses medicinal properties, and they
were used as stimulants by the antients. The buds and
berries of this plant also contain volatile oil, and were
used by the antients as a spice, and are at this day, in Tuscany,
employed as a substitute for pepper. The Tuscanos also pre-
sare a kind of wine from the myrtle called myrtadunam.
The berries are used at the present day in Greece as a
remedy in the diarrhoea of little children. The mode of
administering is to soak them in vinegar, and when distilled
they form the perfume sold in France under the name of
*Ée d’Ange.* In addition to a volatile oil the myrtle
contains two other substances in medicine of varying parts
have an stringent action, and have been used for this purpose.
In Greece, Italy, and the South of France, the bark is used for
tanning.

The myrtle is a half-hardy plant in this climate, although
many individuals have lived and borne our winters for above a
hundred years. The myrtle appears to have been introduced
into England in the sixteenth century. There are at the
present time many fine myrtle-trees in Great Britain and Ireland.
At Cobham Hall, in Kent, there are several specimens 50
feet high. In the Isle of Wight it forms the hedges of many
gardens. The fruit is not eaten, but may be cultivated by-protection during the winter. Several varieties of
the Myrtus communis are found in gardens, of which the
following, from Don’s "Gardener’s Dictionary," may be
regarded as the principal.

*M. malacocarpa* (D. C. Prod. iii. p. 239), fruit blackish.
This variety of myrtle is frequent in the south of Europe and
in gardens, where there are varieties of it with double flowers
and variegated leaves.

Var. a. Romana (Mill. p. t. 184. p. 1), leaves ovate;
pedicles elongate. The common broad-leaved or
Roman myrtle. It is sometimes called flowering
myrtle, because it flowers more freely in England than
any other variety.

Var. b. Tarentina (Mill. Dict.), leaves ovate;
berries rounder. The box-leaved myrtle. Flowers
small, and open late in the autumn. Leaves small.

Var. c. Italica (Mill. Dict.), leaves ovate-lanceolate,
acuminate; branches more erect. The Italian or upright
myrtle.

The orange-leaved myrtle.

Var. e. Lusitanica (Lin. Op.), leaves lanceolate ovate,
acuminate. (*M. acuta* Mill. Dict.) The Portugal
myrtle

Var. f. hortensis (Mill. Dict.), leaves ovate-acuminate; the nutmeg myrtle appears to be only a
variety of this.

Var. g. Belgica (Mill. Dict.), leaves lanceolate acuminate.
The broad-leaved Dutch myrtle. Leaves ovate, dark green.
The double flowering myrtle appears to be of this variety.

Var. h. ensiflora (Lin. Op.), leaves linear, lanceolate,
acuminate. *M. minima* (Mill.), rosemary or thyme-
leaved myrtle.

Native of Greece and the Balearic Isles. The fruit of this is
rather large, edible, with a grateful taste and smell.

The above varieties are constant; but there are others in
the garden which are more variable. It will suffice to give
the names of a few of these.

1. Gold-striped broad-leaved myrtle.
2. Broad-leaved Jew’s myrtle. This variety
frequently has its leaves in threes, on which account it
is said to be in esteem among the Jews in their
religious ceremonies.
3. Lanceolate, striped orange-myrtle.
4. Silver-striped Italian myrtle.
5. Striped box-leaved myrtle.
7. Striped rosemary-leaved myrtle.
8. Cocksemb, or bird’s nest myrtle.

About forty other species of myrtle besides those of the old
genus Myrtus now referred to the genera Myrica, Syzygium,
Eugenia, &c., have been described. None of them yield
products used in arts or medicine, and only a few of them have
been cultivated.

*M. tomentosa* is a native of Cochín China. It is a handsome
shrub, and has been found to grow well against walls in the
south of England.

*M. nammalaria* is a creeping species found at the Straits of
Magellan; and *M. myrtoidea*, a native of the colder parts of
Peru, would probably be found to be half-hardy in this climate.

The species of the genus Myrtus grow well in sunny
places, and cuttings readily strike roots in sand or mould.

(Don, Gardener’s Dictionary; Loudon, Arboretum Brit.;
Frans, Synopsis Florae Classicae; Burnett, Outlines of Botany;
Lindley, Flora Medica.)

*MYRTY*. The family is native of Asia. The type
is *Myrtus communis*, a native of the Hague, where he
was born about 1560, was the best portrait-painter in England
during the reign of James I., and previous to the arrival
of Vandyck, to whom he was little inferior. He was in England
in the time of the civil war, but attained to great cele-
brity until he was appointed one of his court painters by
Charles I. in 1625, with a salary of 20l. per annum, and in
the following year he received in addition 120l. for pictures
painted for the king. Mytens now executed many portraits
of royal and distinguished personages, some of which are at Hampton Court; and he was in great favour until about 1632, when he was so much discontented at the favour shown by the king to Vandyck, that he solicited Charles for leave to retire to his own country, but the king, learning the cause of his dissatisfaction, entreated him to remain, and told him that he should have work enough both for him and Vandyck. Mytens remained, but apparently for a short time only, as none of his works in England bear a date subsequent to the arrival of Vandyck. The two rivals however parted apparently on good terms, for Vandyck painted the portrait of Mytens, and it is engraved in the collection of Vandyck’s portraits, by Pontius. Mytens returned to the Hague, and was still living there in 1636, when he painted a portion of the ceiling of the town-house of that place. His style was bold, firm, and natural, his colouring mellow and harmonious, and his pictures are frequently enriched by warm landscape backgrounds. There are many of his portraits at Hampton Court, of which the full-length of James, first Marquis of Hamilton, is an excellent picture: there are here also Prince Rupert when a boy, and the dwarf Sir Jeffrey Hudson, who, when seven years old, was served up in a pie at Burleigh, at an entertainment given by the Duke of Buckingham to Charles I. and Henrietta, and was presented by the duchess to the queen, who kept him as her dwarf. Hudson was then only eighteen inches high; he grew, after he was thirty, to the height of three feet nine inches. Mytens introduced this dwarf in a large portrait of Charles and his queen, which was in the possession of the Earl of Dummore. Sir Jeffrey died a prisoner in the Gate-house, Westminster, in 1682, aged sixty-three: he was imprisoned upon suspicion of being concerned in the Popish Plot.

(Walpoole. Anecdotes of Painting, &c.,)

**MIXYNA**, a genus of cartilaginous fishes, of the order **Cyclostomi**. It is synonymous with the **Gastrobranchus of Bloch**. The **Myzine glutinosus**, or glutinous Hag, is the type. This curious animal is shaped like an eel, and measures when full grown about one foot and a half. The head is scarcely distinguishable from the body, and is obliquely truncated in front, terminating in a large round mouth, the frame work of which is a membranous maxillary ring, furnished above with a single tooth. The tongue is furnished on each end with two rows of strong teeth. Eight filaments surround the mouth. In the middle of its superior margin there is a single round spiral thread. It has no eyes. The branchial openings are two, and are estimated at about one-fourth the length of the body, below the mesial line. The skin is naked, and very slimy. Along each side of the belly there is a row of pores, which furnish the mucous secretion. An obscure fin runs along the hinder portion of the back, is continued round the compressed tail, and beneath the anal opening, which is placed upon the hinder side of a dark bluish-tinted column, and which is white beneath. The **Myzine glutinosus** is not uncommon in the Scandinavian seas, and is frequently taken off the north-east coast of Britain. It enters the mouths of fishes caught off the line of the fishermen, and eats up all the soft parts of their bodies, leaving only the skin and bones.

The very anomalous characters of this fish have at different times caused naturalists to place it in more classes than one. Thus Linnaeus classed it among Verruca; Modeer, among Amphibia; and O. F. Müller among Molliacea. That it is a true fish, though very low down in the series, has now been placed beyond doubt. It has furnished the subject of many elaborate essays. The most valuable is the celebrated memoir on the Anatomy of Myzinoidea, by Professor John Müller, published in the Transactions of the Berlin Academy for 1834, illustrated by admirable anatomical drawings. In that memoir the author proposes the following arrangement of the cartilaginous fishes, in which the exact position of **Myzine** and its allies in the series is well shown.

**CHONDROPTERYGII**.

**Skeleton cartilaginous, cranium without sutures.**

1st **Order.** **BRANCHIOPTERA.**

1st Family, **Cataphracta.** Cartilage of the cranium, and skin of the trunk covered at intervals with cartilaginous tubercles.

**Sturiones.** Genus 1. **Sturio.**

2nd Family, **Nuda.** Body without tubercles.

**Scotopterygia.** Genus 2. **Scotopterus.**

2nd **Order.** **HOLOCEPHALA.**

Genus 1. **Chimaera.**

Genus 2. **Cithorhynus.**

3rd **Order.** **PLAGIOPTEROMATA.**

1st Family, **Squali.** The branchial apertures not attached to the head.

Genus 1. **Squalus.**

4th **Order.** **CYCLOPTEROMATA.**

1st Family, **Hydropsia.** Palate imperforate.

Genus 1. *Petroglossum.*

(Müller enumerates only one species, the **Myzine glutinosus** of the northern seas. A representative species has since been made known from the Antarctic seas.)

Genus 2. *Beloellota.* (The fishes of this genus differ from the Myxine in having eyes, and more than one branchial spiracle.)

(Müller enumerates four species as certain, viz. : B. hexastroma and B. heterotrema from the Cape of Good Hope; Heterotrema from the South Sea, and Forsteri from New Zealand. B. Donwegi is regarded as doubtful.)
NAGPOOR, a district formerly included in the province of Berar, in Hindustan, but now in the adjoining province of Guandwana, of which the city of Nagpoor is the capital. Ellipoor is the capital of Berar. The palace and seat of government of the raj of Berar is at Nagpoor, and hence he is as frequently styled the raj of Nagpoor as the raj of Berar. The state of Berar, or Nagpoor, is one of those over which the British authorities hold full political sway, with right of intervention in case of internal disturbances, and they have a political agent resident at Nagpoor. The British government is bound by treaty to protect the raj of Nagpoor, and he is bound to pay the British an annual subsidy of 80,000L, to maintain five regiments of infantry and four regiments of cavalry, and a contingent force of 1000 cavalry to co-operate with the British in case of war. The area of the state is about 64,000 square miles, the population about 2,600,000, and the estimated revenue 350,000L. That portion of Berar which lies to the west of the river Wurdah is included in the territory of the Nizam of Hyderabad; and the title of rajah of Berar is a hereditary one, the present one being rarely able to work comfortably with another man's hammer; and hence, he observes, 'as they are somewhat given to tramping from place to place, each workman generally carries with him a hammer and a chisel, and can form anything which weighs about two pounds, he makes, including the cutting up of the nail-rod into convenient lengths, and re-uniting them when they became too short, no less than 1,083,856 feet and from the first to the last of the nails, which were heated 42,836 times. This task, is, Holland states, allowed to have been as much as three ordinary men could perform without difficulty.'

For some purposes nails formed by the much cheaper process of casting have been long used instead of those wrought in the manner above described. Common cast nails are, however, so clumsy and so brittle that they can only be used for a few coarse purposes, as in plasterer's work, and in the nailing up of fruit-trees. By the introduction of great improvements in the manufacture, however, a very useful kind of cast nail, of an exceedingly pure material called malleable iron, has been successfully introduced for certain descriptions of workwood. Nails of this kind are very neat and regular in their appearance, being cast with great accuracy; and they are anodised to such perfection that the metal will bear far more bending than ordinary wrought-iron without injury. This extraordinary degree of tenacity is, however, obtained at the expense of rigidity, such nails being often nearly as soft as copper, and therefore quite unsuitable for use in hard woods.

The comparatively high price of wrought nails, owing to the great amount of manual labour required in making them, and the insufficiency of cast nails as a substitute for them, has led to the introduction of many highly ingenious machines for forming nails by cutting, stamping, or compression, out of plates or rods of rolled iron, and with such success that, for the ordinary purposes of the carpenter and joiner, cut-nails, varying in size from the smallest tack or brad up to spikes of six inches or more in length, have almost superseded those wrought by hand, which like the Batlaves' 'Perfection on Nails,' the Encyclopaedia Metropolitana, the earliest machine for nail-making was that contrived by Mr. French, of Wimborne, Staffordshire, in 1790, in which no material pressure was made, but the only operation consisted of making nails by the hammer, but labour was saved by working hammers by water-power, so that women and children might perform work which would otherwise have required the strength of men. Barlow describes the machine as being in which the various processes of rolling, pressing, stamping and cutting are introduced; but for the details of such machinery we must refer to his work, 'The Baths of Holland for Fire and Art,' Heber's 'Dictionary of Arts,' and Heber's 'Engineer's and Mechanic's Encyclopedia.' Dr. Ure attributes the invention of cut nails to the citizens of the United States, observing that, according to a report by the secretary of the House of Repre-
chametsis, so long since as the year 1810 they possessed a machine which performed the cutting and heading at one operation with sufficient rapidity to cut out more than 100 nails per minute. In the process now most commonly followed nails are cut from sheet-iron of suitable thickness, which is first reduced, by cutting transversely, into strips or rails sufficient to be equivalent to the number of the nails.

These strips are then applied to a machine in which a chisel-shaped cutter descends with sufficient force to cut off from the end of the strip, at each downward stroke, a narrow piece sufficient to form a bevel. As the nail is driven into the face of a tapping form, the cutter must be so fixed as to form a slightly oblique angle to the direction in which the strip is pushed into the machine, and this obliquity must be reversed or the nail will be beveled on one side only. This machine was adopted in comb-cutting machinery. [Coma, P. C. S. P., 1898.]

If the nails are to be of any of the kinds to which the term nail is specifically applied, as distinguished from brads, the action of the cutter is simply reversed, so as to reduce the strip of iron into long, wedge-shaped pieces, and the pieces thus separated are subsequently headed by pressure or stamping, so as to form finished nails; but if the nails are to be of the kind, the action of the cutters must be so modified as to produce cuts alternately at right and oblique angles with the edges of the strip. Nails of this kind need no subsequent heads, but would be soldered by the application of the eye of the nail. The accuracy with which this operation is performed may be seen by laying together side by side, heads and points alternately, a number of cut nails or brads, when it will be found that they really do resemble a regular regular.

In some regularities the cutters do not vibrate or vary their position, but the strip of iron is turned between each cut, so as to produce the same effect. Brads are frequently cut out of hoop-iron instead of transverse strips of sheet-iron, as above described; but the practice is much to be deprecated, although the brads so formed have a rather neater appearance than others; for it is evident that all, in the operation of rolling, the fibre of the iron is laid transversely in the strip, instead of along the nails cut transversely from it, thereby rendering them very weak and brittle. The advantage derived from the superior squareness of cut nails, as compared with wrought nails, is alluded to above.

Some peculiarities of considerable importance is that, as much nails are usually tapered in one direction only, their points are somewhat chisel-shaped, and, though sharp, as broad as the body of the nail. If, therefore, such a nail be placed with its chisel-shaped point across the grain of a piece of soft wood, it may be driven in without boring, and without the risk of splitting, which would arise if the nail were, as most wrought-nails are tapered on every side.

In some of the coarser operations of carpentry nails are secured by clinching, or bending down their points with the hammer; but they are driven commonly through with their heads intended to hold together. Hebert notices a very neat and secure substitute for this rather clumsy expedient, which consists in placing on the projecting end of the nail a little ball of common iron called a black ball, and then clinching or riveting the end of the nail down upon it. He states that this mode of fastening appears, though without reason, to be almost entirely confined to boat-building.

Nails of iron with ornamental brass heads are much used for hanging pictures upon, and for other purposes in which the heads of ordinary nails would be unsightly; and nails wholly formed of brass, copper, or brass and copper alloys, are used in ship-building, and for a few other purposes. For the mode of coating small iron nails or tacks with tin, for use in cases where rusting is injurious, see N. Kitchevan. [Examinorlay, P. C., 1842.]

NANTEUIL, ROBERT, a celebrated French engraver and draftsman, was born at Rheims, in 1630, and was the pupil and friend of his brother, N. Raimond. He engraved chiefly portraits, in which class he is one of the most distinguished engravers, though he generally engraved the head only, without accessories; but he frequently executed them of the most enlarged and spirited kind—so took an interest in length of life in passing it in a very able manner; but as he used these chiefly to engrave from, few of them have been preserved. He engraved in line and in stipple, and generally combined both styles, stipple being his favourite mode. He endeavored to express colour, and to a considerable degree in his prints. Nanteuil died in 1678, and though he lived to the age of forty-eight only, he has engraved nearly 800 plates, almost exclusively portraits, and comprising many of the princes of Europe, and most of the celebrated men of France during the reign of Louis XIV., of whom the author has written a life in each of the principal periods of his life. His master-pieces are J. B. van Steenbergen, after Duchatel, known as l'advocat de Hollande, 1608; M. de Pompeonne, after Le Brun; D. M. le Mothe de la Vuye, after Lorraine; and a portrait of an old lady, in the possession of Mr. H. J. M. de la Porte. [Welette et Levesque, Dictionnaire des Arts, &c.; Heber, Manuel des Amateurs, &c.]

NARDOSTACHYS, a genus of plants belonging to the natural order Valerianaceae. The limb of the calyx is 5-parted; the lobes ovate, oblong, acute, leafy, somewhat toothed and permanent. The corolla is regular, ecalcarate, usually 5-lobed and bearded in the throat. There are four stamens, which are closely united and vary; the anthers are oblong, and the filaments are herbs with sweet-scented perennial roots, which are beset with erect flers at the neck.

N. lowii or a large herbaceous plant with a long hairy tap-root. The stems are perennial, very short, and simply divided into a number of shaggy, scaly crowns, from which the leaves are produced. The branches erect, downy, and a few inches high. Leaves oblong, lanceolate, rounded, downy; those at the base acute, the upper ones obtuse. The flowers are of a pale pink colour, clustered in the axils of the upper leaves, which form a kind of involucres for them. It is native of New Zealand, the Sandwich, and in Dublin, Bengal, and Deccan. This species is the true Spikemead of the ancients, and is esteemed not only as a perfume, but as a stimulating medicine. Oriental writers give it as a remedy for a multitude of diseases. It seems to be really valuable in cases of epilepsy and hysteria.

N. grandiflora is a prolific species, long glabrous leaves, with solitary terminal flowers. The capsule is downy, and the lobes of the calyx evidently dentilicate. It is native of Nepal and Kumaon.

These plants should be grown in pots, in a mixture of loams, peat, and sand, and placed among other Alpine plants. They may be propagated by cuttings or by seed.

(Don, Gardener's Dictionary; Lindley, Flora Medica.)

NARTHIECIUM, a genus of plants belonging to the natural order Juncaceae. The perianth is partly coloured, of 6-linear lanceolate persistent leaves. The filaments are woolly, and the style undivided. It has a simple obtuse stigma. The capsules pyramidal, 3-celled and 3-valved. The placenta extends only a short distance up the inner edge of the dissection. The seeds have a long villous appendage at each end.

N. ocefrangum, the only British species, has linear sword-shaped leaves, pedicells with one bract at the base, and another above the middle. The perianth longer than the stamens, and considerably shorter than the capsules. The flowers are bright yellow. This species is distinguished especially by its seeds dry and naked.

(Babington, Manual of British Botany.)

NASIREANS. [NAZARENES, P. C.]

NASMITH, DAVID, was born in Glasgow, on the 31st of March, 1765, and was apprenticed to a tinsmith at the age of sixteen he made a public profession of religion by joining the church in Nhill Street, under the pastoral charge of the late Rev. Dr. Grose. He was born in Sighthill, near Glasgow, on the 27th of December, 1765. He had a great exertion to prepare himself for the Christian ministry; but as his friends did not encourage the attempt, he returned to secular employment, but engaged with great zeal in Sunday-school teaching the establishment of adult schools, the subsequent instruction of prisoners, and other philanthropic efforts. In the autumn of 1821 an event occurred which, by affording enlarged scope for his benevolent desires for the religious and moral improvement of his country people, was all in direct development of a character which, for disinterested devotedness, has been rarely equalled. 'The conductors of the various religious and benevolent societies in Glasgow,' observes Nasmyth's biographer, 'had to express a deep sense of the services of Sir George Taylor and his friends, and of the untiring and indefatigable zeal and perseverance with which he had laboured in embracing the most honourable and noblest of offices, and of the invaluable services which he had rendered to the community and to the country.'

In the completion of their plan required the services
of an active secretary, who should be common to them all. In answer to an advertisement for such an officer, Nasmith offered his services, and in the first year of his employment, devoted sixty pounds, though the interests of twenty-three societies thus devolved upon him. In this office he was brought into frequent communication with committees composed of ministers and laymen, making the establishment of local missionary societies his especial care, and he gained the personal esteem of many of the most eminent men of Glasgow; and the remarkable course of mental training thus afforded had the effect of fitting him for the singular career he was subsequently to pursue. To this biography attributes 'the free, easy, and noble air' by which he was distinguished in after life, and to which he appears to have been largely indebted for his influence over men who were strangers to his person, and who, in many cases, he was inclined to regard his projects with prejudice and distrust. 'Even on the first interview,' observes Dr. Campbell in the 'Memoirs' upon which this article is chiefly based, 'no stranger could escape the impression that he was a man of extraordinary integrity and sagacity, piety and benevolence.'

'Mr. Nasmith,' observes Mr. Astbury, 'was a man of consummate ability and tact in the formation of societies.' 'It was,' he remarks, 'his great talent;' and it was manifested in his power of 'directing a committee without assumption on his own part, patiently attending to the various opinions of members, and gradually shaping the committee to his own decisions, and gently intimating his own judgment, which, being founded on great experience, was generally adopted.' In this office he also, to return to Dr. Campbell's account, 'obtained a very distinguished character for management, and when he left his charge he had discovered its wants; he saw directly before him the amount and character of the agency provided for the supply of those wants; and hence he ascertained how much of those wants remained unprovided for. While faithfully discharging his onerous duties in connection with the existing philanthropic societies of Glasgow, Nasmith applied himself also to the formation of such new associations as were deemed necessary for religious, scientific, and charitable purposes, and so contributing to the welfare of that and other populous places. Young Men's Societies, or associations for promoting the religious interests of young men, whether in the form of a trade union or a co-operative union, or both, from their position, and in that of a resident in a large town, and for directing their united energies into channels of benevolent exertion, occupied then, as in his later years, a large share of his attention; and in a letter upon the subject addressed by him to Professor Buchanan in February, 1826, he states that he had been the means of forming about seventy such societies, in the United Kingdom, France, and America, since the close of the year 1823. A still more important project, and one which has proved far more extensively successful in practice, was the formation of city and town missions, or societies for carrying religious instruction, by means of lay agents wholly devoted to the active support of their work, into those districts into the very haunts of vice and dissipation. Attempts had been previously made in a few instances, and on a small scale, to accomplish this object; but the difficulties of the task, especi- ally in the case of town missions, had been so great, that the attempts of the Christian Church, had impeded their success. In spite of such difficulties, Nasmith succeeded in establishing, at the commencement of 1826, the 'Glasgow City Mission,' which, though commenced by the congregation to which he belonged, was constituted on a systematic footing, that, before the end of its first year, eight evangelical denominations of Christians were united in its management, and eight missionary societies were employed. The success of this society encouraged Nasmith to print and circulate widely, not only in the British Islands and America, but also in France and other parts of the continent of Europe, a brief account of its design, with testimonials of its usefulness. In the same year Nasmith married Miss Hartridge, a native of Kent, who was then residing in Glasgow, and who became a most valuable coadjutor in his benevolent designs. In 1828, his health being impaired by the arduous duties of his office, Nasmith resigned his connection with the Institution House at Glasgow, and from that time until his death he devoted himself wholly to the exercise of work for which he was better fitted. His public character and name were then fully known among the agent or missionary, travelling from place to place to promote the establishment of city and town missions, young men's societies, and other kindred institutions. He chose his work, and missions for such an undertaking was of no ordinary character, since it involved the relinquishment of any settled means of obtaining a livelihood, and of all prospect of obtaining a station to which his talents entitled him; while he had no property on which to rely even for travelling expenses, nor any society on which to fall back for support. His first removal was to Manchester, followed by Birmingham, and then to the prosperous city of London. Having subsequently visited London, and his wife's family in Kent, he returned to Glasgow, and thence again to Dublin, where he formed a society for promoting the extension of local missions. In 1829, he returned to London, and whence, in 1829, he proceeded on a tour through the south of Ireland, establishing missions in Cork, Limerick, Waterford, and several other places. In the following year he performed a similar journey, with the like result. In 1830, he returned to the north of Ireland, after which he returned to Glasgow, and prepared for a voyage to the United States on the same benevolent errand. Arriving at New York in September, 1830, he formed a city mission there, and continued it for about three months' duration, visiting and establishing similar societies in many towns in the United States, after which he returned to New York, sailed to New Orleans, made some visits in Philadelphia, and afterwards, preparing for a third time at New York, proceeded to Canada. How completely disinterested Nasmith in these travels may be seen from the fact that while his necessary expenses were defrayed in New York, when he first left his native country for Ireland, to December, 1831, when he returned from America, where he travelled about 3000 miles, amounted to rather more than 67L, a sum wonderful when considered that he was deprived of the benefit of his scanty resources. Fecund difficulties, however, could not repress his ardour, and it was not long before he visited Paris and established a Christian mission there, and set on foot a similar establishment in Scotland. He studied in Edinburgh, and in March, 1835, fulfilled a long-cherished intention of removing his residence to London, for the purpose of establishing a city mission. His enterprise, observes Dr. Campbell, 'was not preposterous. Many of the best friends of the object at which he aimed deemed it utterly hopeless to effect that object by the means of a single society or of different sects; but he secured joint efforts of churchmen and dissenters. Nasmith, who was of too catholic a spirit to care to what section of the Christian Church his fellow-labourers belonged, so that they were real Christians and united in the desire to impart the highest benefits to their fellow-men, and who, indeed, in answer to inquiries respecting himself, would say 'I am a Catholic Christian,' neither suffered objections or difficulties or impediments to deter him from his aim, nor to induce him to lessen its moral grandeur by identifying it with sect or party. The London City Mission was therefore commenced in conformity with the design of its founder, but without the active support of a single sect. It is still in being and flourishing, and, afterwards, finding its fears groundless, heartily united to carry it on. Operations were commenced with only four missionaries, with salaries amounting in the whole to 297L per annum; but so large has been the progress, that in 1845, at the date of the tenth annual report, the number of missionaries employed was 121, and the expenditure in salaries alone for the preceding year had been 2400L, exclusive of all other expenses incidental to the mission. In the same year the number of domiciliary visits, and visits to hospitals, asylums, and other places where the poor and ignorant are con- gregated together, paid by the mission, amounted to 544,908, of which 39,469 were to the sick and dying. In a majority of the latter class of visits the agents of the city mission were the only individuals by whom religious instruction and comfort were carried to the bed-side of the sufferers. The distribution of Bibles and religious tracts, the holding of religious services in neglected neighbourhoods, and various other benevolent operations, are also carried on by the missionaries, and special provision has been made for the appointment of agents suited to their peculiar necessities, for the spiritual wants of cab-drivers, and of the numerous Lucerne, Germans, and other foreigners in the metropolis, and for the comfort and relief of the most wretched and abandoned, the missionaries have obtained access, and often with the best results, to homes of misery and vice which no other agency has been able to approach. They have been agents of moral police, of the efficacy of which the reports of the society and the documents published monthly in the 'London City Mission Magazine' afford abundant proof. One missionary alone, in Clerkenwell, has, according to the report above quoted, seen

NA U C L E A, a genus of plants belonging to the natural order Rubiaceae. It has a calyx with an oblong tube and a short truncate or 6-toothed ovate, mitten-shaped, with a slender tube, a naked throat, and 5 spreading oval oblong lobes. The anthers are inclosed, and always shorter than the lobes of the corolla. The capsules are 2-valved, subglobose, or oblong-globose, and when the seeds are ripe they open towards the base. The seeds numerous, imbricate, winged, fixed to oblong placenta, which are adnate to the dissepiment. The embryo is invested in a silky albumen. The leaves are ovate-oblong, or oblong-lanceolate, with rounded or acute base, and wavy or dentate, or entire at the base, of the head of flowers, but with linear palea among the flowers, which are crowded and sessile. The species are unarmed trees, rarely shrubs, and natives of India and tropical Asia.

N. Cadamba has bracteate branches, petiolate, coriaceous, ovate leaves, triangular stipules, terminal solitary peduncles, usually shorter than the heads, which are globose. The flowers are corolla-coloured, corolla of the size of a small apple. The style is white and exserted. The seeds not winged, the leaves from 6 to 10 inches long.

Kuching is one of the oldest of the places of the interior, it is bounded on the north by the river Kuching, on the south by the mountains Calcutta and Malabar, where it grows to be a very large tree, and is ornamental and very useful from the extensive shade it affords.

N. perpsefolia has petiolate obovate oblong leaves, oval stipules, and terminal solitary peduncles; sometimes the peduncles are in tripods, when the middle one is the shortest. It is native of the East Indies and all the coast of Coromandel, but chiefly in the mountains of the Philippines. The flowers are light yellow, and globular, about the size of a plum. The wood is of a pale chestnut colour, firm, and close-grained; it is useful for purposes where it can be kept dry, but when it is not dry it will swell. A true element for cabinets.

N. cordifolia is prized on account of its wood, which is light and durable where it can be kept dry. It answers well for furniture. There are thirty-seven species of this genus in the Indo-Malayan region, of which at least nine possess any peculiar qualities which entitle them to particular notice. They are of easy culture. A mixture of loam, sand, and peat is the best soil for them, and they readily take root under a hand-glass in the same kind of soil.

The Nauclea Gambia of Hunter (Linnaean Transactions, vi. ix.) is now Uncaria Gambia. (UNCARIA, P. C.)

NAU C R A T E S, a genus of fishes of the mackerel tribe having fusiform bodies, tails heeled at the side, and two free spines before the anal fin. The N. acus raptor is probably known as the Pilot Fish, and is remarkable for its habit of following vessels often for many hundred miles. Mr. Crouch, in the 14th volume of the 'Linnean Transactions,' has recorded an instance of two individuals of this species which accompanied a ship from the Mediterranean to Boston, whereas they were taken by a net. The N. acus raptor is about a foot in length, and is remarkable for the beauty of its colour, being of a silvery pale blue banded by broad and deep transverse dark blue bands. The young possess this beautiful tint. Mr. Traub, the brother and master of the younger Polycterus of Argus, and of the N. N. A U C Y/DIE (naucyd), a Greek sculptor, who was born at Argos, and was in repute, according to Pliny, about 650 B.c. He was the son of Philocles, the brother and master of the younger Polycterus of Argos, and of the Younger Polycterus. He was one of the most important artists between Alcamenes and Praxiteles. Pliny mentions a Mercury, a Discobolus, and a man sacrificing a ram, by him. Pausanias notices six
other ci... works: a Hebe, in ivory and gold, placed near the celebrated chryselephantine statue of Juno at Myconae by Polykleitus, and two Aratas and four victors at the Olympic games, one of Euclees at Rhodes, two of Chionos, one of which was at Olympia, the other in the city of Tenedos; Neacles defaced the palm-tree of Nearchus, and another Bacis the wrestler. A tenth work by Naucrates, a bronze statue of Erinnis, is mentioned by Tattian. The two statues of Chionos were, according to Pausanias (vi. 9), his best works; but, when new set up, they were so well known Discobolus in repose, standing with the quoit in his hand, is sometimes called the Discobolus of Naucrates, but without the slightest foundation.

NAUTON, SIR ROBERT, a diplomatic statesman, was born in 1593, and was the son of Henry Naution of Alderton, in Suffolk. He studied at Trinity College, Cambridge. He attended his uncle, William Ashby, when he was sent as ambassador by Queen Elizabeth to Scotland in 1649, and being sometimes trusted with the management of important business connected with the mission, was then initiated in diplomatic life. In 1596, he was sent by Essex to France, with letters to Antonio Pérez, formerly Spanish secretary, probably with a view of securing the services of three Venetian adventurers, Zauli, goboso, senapiti, or at least of sounding their intentions. Returning home, he was, in the same year, appointed tutor to a young gentleman named Vernon, of whom the Earl of Essex was guarantor. He proceeded to France in 1597, to repeat the mission to France, in company with the French ambassador, the Duc de Bouillon; and it is manifest that the object hidden under his appointment, and his journey, was to give Essex the services of a man who might take a hand on the French court. He seems to have been naturally of a candid disposition, which did not easily mould itself into the plant morality necessary for successfully conducting the flagitious diplomacy of that age. He wrote many complaining letters to his patron. 'The best allowance of credit I can have,' says he in one of them, 'is but in nature of betwixt a pedagogue and a spy; both trades I have not, nor can I find any eyes but those of their eyes with whom I live as my own.' After the fall of Essex, little seems to be known of him, until 1614, when he reappears as member of Parliament for Helston, a favourite of 'King James on account of his scholarship, and one of the persons patronised by Buckingham. He was sworn Secretary of State, on the 8th of January, 1618. Having afterwards opposed the favourite's friend, Gondomar, the Spanish ambassador, he was deprived of office, but he was subsequently appointed Master of the Court of Wards. He died on Good Friday, 1635. His 'Fragmenta Regalia: memoirs of Elizabeth, her court, and favourites,' was greedily perused in manuscript, and frequently referred to, and quoted in 1641. It has passed through several editions. This little book is remarkable as one of the very few which in that age noticed political events and characters in their relation to the court, and preserved the documents by which a writer brought to bear a sagacious and artistic style.

(Trans. prefaced to Fragmenta Regalia, 1684.)

NEALCES (Nealxen), probably of Sicyon, a celebrated Greek painter, contemporary with Aratus of Solconyr, about 213 B.C. Few of his works are mentioned, but he was the most celebrated painter of his time. Pliny mentions a Venus by him, and a battle between the Egyptians and Persians on the Nile. He is known to have drawn in the locality of his battle. Nealces painted an ass drinking at the side of the river and a crocodile lying in wait for him, an ingenious application of accessories, of which there are also many other examples in the history of Greek painting. Nealces is one of the painters whose tradition represents as having succeeded by accident in painting the form on a horse's mouth with his sponge. Aratus, in his poem against the tyrants, waged war even against pictures, and resolved to destroy all their portraits which were preserved at Sicyon. This he did with one exception; Nealces saved the portrait of Aratrus by Melian. This was said to have been painted by a certain Polually. Aratrus was represented standing by a chariot of Victory; Nealces painted out the figure of Aratrus, and substituted a palm-tree in its place. 'The piece was so admirable,' says Pliny, 'that Aratus could not feel the art that was displayed in it; but his hatred of tyrants soon overruled that feeling, and he ordered it to be defaced. Nealces the painter, who was honoured with his friendship, is said to have implored him with tears to spare that piece; and when he found him inflexible, said, 'Aratus, continue your struggle with tyrants; but do not destroy Nealces.' Aratus gave his consent, and his old masterpiece still remains. But Aratus, but did not venture to put anything in its place except a palm-tree, and however that there was still a dim appearance of the feet of Aratrus at the bottom of the chariot. (Longhorn's Transl.) Such a claim of fame and of the barest shadow thereof, has been spoken of may have arisen sometime after Nealces altered the picture; such accidents frequently happen in painting out, unless a considerable body of colour is used.

Naxandra, the father of Naxos, was by Neaces, who was distinguished for her paintings; and his colour-grinder, Erginons, became a painter, and acquired great honour through the celebrity of his pupil Pasias.

(Pliny, Hist. Nat., xxxi. 11, 40; Plutarch, Aratus, 13.)

NEBULAE. [Star, P. C., pp. 449, 450.]

NECTANDRA, a genus of plants belonging to the native order Lauraceae. It has a 6-parted rotate calyx, deciduous segments, the three outer rays of which are 9 anthers which are ovate, nearly sessile, with 4 cells, arranged in a curve, and distinct from the tip of the anther, the cells of the interior anthers inverted. The glands are in the axils of the anthers, the back of the other segments next their back. The fruit is succulent, more or less immersed in the tube of the calyx, which is changed into a truncated cup. The flowers are panicled or corymbose, axillary lax and pretty amorphous.

N. cymbammus is a tree nearly 100 feet high, growing in the woods of the Orinoco, near S. Fernando de Atabasco, where it is called Sanafras, and also in the ancient forests of the Rio Negro in Brazil. The branches are smooth, the leaves oblong, lanceolate, papery, and shining above. The cup is large with a double edge. The bark aromatic, bitter, and stomachic. Martius suspects that it is one of the ingredients in the famous Wooroy poison of Guiana.

N. Cinnamomoides has oblong leaves tapering into a fine point, acute at the base, between papery and leathery, naked, smooth, and shining above. The bark is finely downy beneath, with numerous distinct narrow costal veins. The bark has the smell and flavour of cinnamon, as which it is used in New Granada.

N. Puchary major has oblong or elliptical leaves tapering into a narrow point, smooth, reticulated, and of the same colour on other side. The cup of the fruit is very large and spongy. Martius assigned the Pichary bean to this plant. In the early months of the year the fruit drops from their cups to the ground, and are collected by the natives, cleaned and dried by a gentle heat. They are prescribed in dysentery, diarrhoea, cardialgia, strangury, &c. The bark has the smell of fennel mixed with the smell of the fruit. (Linsey's Flora Medicinal.)

NECTARINE. [Amygdalas, P. C.; Peach, P. C.]

NECTARY, in Botany, a term used by Linneus to designate those appendages of the corolla which secrete honey. The term has however been used in a general sense to express any organ existing in the flower between the corolla and pistil, and which could not be rightly assigned to these or the stamens. Such parts or appendages of the flower have had many other names applied to them, and some much more commonly than nectary. A common form of appendage of the corolla is called corona. This organ is formed at the base of the limb of the corolla, and forms sometimes an undivided cup, as in the Narcissus, and when it is called by Haller a capybus. When it is separated into several parts, as in Silene and Brodiaee, it forms the lamina of some writers. In Stapelia this organ forms a thick solid mass, covering the honey of the stamens. It is here called the orbiculus. When this appendage is accompanied with little projecting processes, they are usually called the anthers. *

* These are not the words of Plutarch; he says the feet were under the chariot, and as they say ' ' , when the figure was painted out. The usual meaning of ' ' is ' ' , ' the whole earth was standing by it. The old version of Aratus is right. That of North, who translated Aratus, is partly wrong.
are called corona, or horns; the upper end of these is the beak or rostrum, and their back, if dilated and compressed, is called the caruncle. Occasional horns are a second set of horns, which alternate with the first, and are called ciliula; the circular space at the top of the orbicularis is the scutum. When the lamellae are small and scale-like, and overarch the orifice, they are called a frill. Link proposes to call all appendages which are referable to the corolla paracorolla, or, if they consist of several pieces, parapetaloids, and all appendages referable to the stamens parastamens. The peculiar filiform appendages of Passiflora he calls paraphyses or paraphractes.

The real nature of these appendages is a point of some importance. In some instances they appear to be simple expansions of the cellular tissue and epidermis of the part on which they are seated, and in others they are evidently abortive stamens or petals. Thus the little bodies found in the claw of the petals of Ranunculus may be regarded as an expansion of the tissue, whilst the filamentary appendages seen in the genus Passiflora are evidently metamorphosed petals. The various forms of corona may be assigned to one or other of the above causes. This subject requires investigation, and it would be well if a more simple and intelligible nomenclature could be applied to these parts of the flower; for, however unimportant at first sight such organs may appear, they neverthless contain some of the most vital parts of the plant, for species, genera, and even orders, which the botanist possesses.

The original name, nectaris, of these appendages was applied on account of the honey which the tissues of these organs frequently secrete. They were on this account called by Meyen compound glands. It was supposed by Kurr that the auxiliary glands were inculcated, and that the included secreted honey till the fruit began to develop itself. But that the function of the nectary has no direct relation with the object of the function of the fruit, that is, the development of the seed, is proved in an experiment by Kurr himself, in which he found that the seeds of plants become perfectly matured, although he had in the early stages of the growth of the flower removed the nectaris. As to what may be the destination of the nectar and the secretion in these flowers, any more than in other parts, no examination of their structure has hitherto pointed out. They do not however possess the power of secreting sugar and other secretions in any greater degree than the petals and other parts of the flower and fruit.

(Lindley, Introduction to Botany; Schleiden, Grundzüge der Wissenschaftlichen Botanik; Meyen, Pflanzen Physiologie.)

NEEDLE-ORE. [Minerology, P. C. S.]

NEGOTIABILITY. [Bill of Exchange, P. C. N.]

NELLIBUMI. [Arabia, F. C. and P. C. S.]

NELIUM, genus of plants belonging to the natural order Nymphaceae. It has many distinct carpal, half immersed in the profoundly honey-combed, obconical, elevated tube, and with a solitary flower in each capsule, which is exarillate, and destitute of albumen. The flowers are large and showy, white, red, or yellow. Both leaves and flowers rise from the surface of the water.

N. speciosa, Pythogorean Bean, has a polypetalous corolla and anthers drawn out beyond the cells into a club-shaped appendage. It is native in slow running streams and tranquil waters, in the warmer parts of Asia. The flowers are very beautiful, small, shining, and generally of a light colour, seldom white. A variety of this species, Tamarua, has its outer stamens sterile, dilated at the top, winged, obcordate, the appendage rising from a notch at the apex. It is native of Malabar. The fruit resembles an instrument once used in play by the French, called Lotus, and is one of the plants supposed to be the celebrated Lotus of antiquity, formerly found in Egypt. It was known to the Grecians, and is mentioned as growing in Egypt by Herodotus (f. 92), Theophrastus, and others. Although now not to be met with in that country, there can be no doubt as to its having actually existed there, either naturally or in a cultivated state, for these authors speak of it in clear and definite terms, and it should have been noticed that the seeds were still preserved, which testify that this species, as the proper Lotus, has obtained religious reverence. It is spoken of as having been used as food by the Egyptians. Both roots and seeds are consumed, and the latter are eaten in a raw state, or roasted, and to be of service in extreme thirst, diarrhoea, vomiting, &c. In China it is called Lienshua, and the seeds and slivers of the hairy root, with the kernels of apricots and walnuts, and alternate layers of ice, were frequently presented to the Emperor and his suite by the principal mandarins. The roots are laid up by the Chinese in salt and vinegar for winter use. Thunberg says this plant is held sacred in Japan, and is considered pleasing to the gods, "the doors of which are in reality the large leaves. The seeds are somewhat of the size and form of an acorn, and of a taste more delicate than that of almonds.

N. lutea has a polypetalous corolla, and greatly resembles N. speciosa in structure. It is native of North America, in lakes and ponds: it has been naturalized as far as Philadelphia. The flowers are yellow, and resemble a double tulip. The seeds are very agreeable to eat, and are much relished by the Indians.

The species of this beautiful aquatic genus should be grown in cisterns, tubs, or large pots, in a rich loamy soil; they require a strong heat to flower to perfection. The pot they are in should be kept full of water while they are growing, but may be allowed to get dry when the flowering season is over. They may be increased by dividing the roots, but are obtained more readily from seeds, which vegetate freely. None of the species have flowered in this country excepting the N. speciosa; they all require a very warm situation in a stove.

Do: Gardener's Dictionary; Burnett, Outlines of Botany.

NEMACANTHUS, a genus of fossil fishes from the colite and liassic strata. (Agassiz.)

NEMASTYLIS, a genus of fossil Annelida, from the lower silurian strata of Lampeter, in South Wales. (Murchison.)

NEMOCERIA, the first family of Dipterous insects in the arizmogynous, and that inclosed in the antennae composed of many joints, an exserted head, a sheathed sucker, and either simple or toothed tarsal hooks. It includes the species of Culex and Aedes, the names given by naturalists to the Mosquitoes and Gnats. These Linnean genera are now greatly subdivided.

NEOTTTIA (serrata, 'a nest with the young in it,' the young themselves), a genus of plants belonging to the natural order Orchidaceae, having the stamens arranged in a long stamen, 2-lobed lip saccate at the base; the stigma transverse; rostellum flat, broad, prominent, entire, and without an appendage.

N. Nithia-aria, bird's nest orchis, is the only British species of this genus. The whole plant is of a pale reddish-brown; the root formed of many thick fleshy fibres, from the extremities of which young plants are produced. The stem is about a foot high, with spreading brown scales. It has no leaves. The spikes are dense, cylindrical, and many-flowered. It is the original Neottia of Linnaeus, and is native of Great Britain and Ireland. (Albington's Manual of British Botany.)

NEPA, a genus of hemipterous insects of the family Hydromeris, the species of which are popularly known as water-contrpions. Their bodies terminate in two long sets, by means of which they acquire a supply of air for respiration, when immersed in the water or mud.

NEPETEA, (a name used by Pliny from Nepes, scorpion, being supposed to be efficacious against the bite of a scorpion; or from Nepes or Nepete, a town in Tuscania,) a genus of plants belonging to the natural order Labiatae, and the tribe Nepetae. It has diverging anther cells, a ringin corolla, the upper lip flat, straight, emarginate, or bifid. The calyx is 5-toothed.

N. Cataria, catmint, has stalked corolate acute leaves, deeply crenated and clothed with a whitish pubescence beneath, the many-flowered white, smooth and glabrous leaf. The stem is from 2 to 3 feet in height, downy or mealy. It is native throughout the whole of Europe and middle Asia, and is plentiful in Britain. The corollas are white, with a tinge of red spotted with purple. The whole plant has a strong smell between mint and pennycroyal. Cats are said to be fond of it, and hence it derives its name; they roll themselves on it and tear it to pieces apparently with much pleasure. Ray noticed that the whole plant was eaten by the cattle, but after the garden were always destroyed by cats, unless he protected them with thorns until they had come into flower; but they never meddled with plants raised from seed, and hence the old saying, 'If cats don't eat the cats will eat it, if cats eat it, cats won't know it.' Ray accounts for this from the fact that by transplanting the leaves become bruised, and the powerful odour is exhaled which attracts the cats to it. It appears to
act as a real aphidaphage upon cattle. Sheep are said to eat it, but do not seem to do so freely in a moist state. All other domes require a good deal of heat to flower well in this country.

**NEUTRIA.** [Cottou, P. C.; Fournier, F. C. S.]

**NEWCASTLE, Duke and Duchess of.** [Cayvendish, Margaret, P. C. S.]

**NEWGATE, Duke of.** [Dance, P. C. S.]

**NEWTON, GILBERT STUART, R. A.,** was born in 1794, at Halifax, in Nova Scotia, where his father was collector of the customs. He came to England about 1820, and, after making a tour in Italy, he entered the Royal Academy. He adopted Watteau in some degree as his model, and produced several excellent small pictures much in the style of that master as regards the figures, yet at the same time displaying great expression and character. His first works which attracted notice were the Farsaken, and the Lover's Quarrel, engraved in the 'Literary Souvenir' of 1826. He painted the Prince of Spain's Visit to Catalonia, for the Duke of Bedford for 500 guineas; it was engraved in the 'Literary Souvenir' for 1831. In 1830 he painted Shylock and Jessica, from the 'Merchant of Venice'; Yorkic and the Grisette, from the 'Sentimental Journey,' and the Abbot Boniface from the 'Monastery:' all in the edition of 1834 printed in 1830. In 1831 he exhibited Portia and Bassanio, another scene from 'The Merchant of Venice;' and Lear attended by Cordelia and the Physician. In 1832 he paid a visit to America, and painted those scenes in which he was elected an academician, he exhibited a small picture of Abelard sitting in his study, a work full of expression and sentiment, and his day in the life of Wakefield restoring his daughter to her mother, Machethe, and a few portraits. His Masque was purchased by the Marquis of Lansdowne for 500 guineas.

His Abelard was the last picture that he exhibited in the Royal Academy, 1835, and it was about this time that he evinced signs of aberration of mind, and these were followed by unaccountable insanity, which however he recovered from four days before his death, and breathed with calmness and resignation August 5, 1835, at Chelsea, aged forty. His will returned with her child to America a few months before his death. He painted slowly, and was laborious and fastidious in his execution. He was also, says a friend, extremely neat and fastidious about his dress, though 'he was far from paying the same attention to his chambers, for his compositions were scattered carelessly around; the finished and unfinished were huddled together, and ivycoke models and bits of ribbon and withered flowers abounded.' This was in 41, Great Marlborough-street, where his principal works were painted.

**Gentleman's Magazine.**

**NEY, MICHAEL,** 1st Duke of the Moskova, Duke of Eichingen, and Marshal of France, was born at Sarre-Louis in Lorraine, on 10th January, 1769. At the age of thirteen he was articled to a notary of that town, but this occupation not being suited to his disposition, he got himself made a captain in 1787 in the regiment of dragoons of the Meurthe. He there soon distinguished himself by his courage and activity, and, after passing through the inferior grades, he became a lieutenant in 1793, and a captain the year following. The skill which he displayed in conducting some partisan warfare in 1794 attracted the attention of General Kleber, by whom he was sirnamed 'The Indeffatigable,' and raised to the rank of adjudant-general. In 1796 he greatly contributed to the victory obtained at Neuwied, and distinguished himself in the engagements of Altenkirchen [Lavenere, P. C. S.], Montaub, and Dierdorf, in which last he made a prisoner. After his exchange he served in 1798 with the army of the Rhine, and after the death of the Duke of Malspal the small body of cavalry he took two thousand prisoners, and obtained possession of that town, he was nominated general of brigade. In the course of this campaign his courage was confirmed by his successful assault of the French barracks, which had been taken prisoners, and he enabled them to clude the sanguinary decrees of the Directory. In 1799 he again served with the expedition against Genoa under General Moreau. We can only enumerate the principal achievements which in this memorable campaign added to his celebrity. They are the capture by surprise of Mannheim (12th March, 1799), the taking of the redoubt at Ratis, and the seizure of all the enemy's artillery at the battle of Iler (5th June, 1800). He was also present at the battle of Hohenlinden [Morkon, P. C. S.], and his bold attack of
column of the Austrians, which he drove back into the forest, greatly contributed to the victory. At the peace of Lunéville he returned to Paris, where he was received with distinction by Bonaparte, who attempted to attach him to his interests, caused him to marry Mademoiselle Auguié, a friend of Hortense Beauharnais. In 1803 he was appointed minister plenipotentiary of the French Republic in Switzerland; on leaving that country, as he was particularly interested in the neutralization of many of their esteeem for his character and conduct, and the moderation with which he carried into effect the measures of his government. On his return to Paris the command of a division was conferred on him, and on 7th December 1804 he was made a Marshal of France by Bonaparte, and in 1804 he was raised to the dignity of a Marshal.

On the renewal of hostilities with Germany in 1805 the direction of the eighth corps of the army was confided to Marshal Ney. A brilliant achievement in this campaign, the capture by storm of the village of Echelignes (October 6th, 1805), in which the Russians, under General Lefson, lost fifteen hundred men killed and wounded and two thousand taken prisoners, was attended with the most important results. The impetuous courage and persevering skill which this marshal displayed on that occasion had been witnessed by Napoleon, who in commemoration of it afterwards bestowed upon him the rank and title of Duke of Echelignes.

But it was perhaps during the Prussian campaign of 1806 that Ney's military reputation rose to its greatest height. Of the three victories by which he distinguished himself the chief are, the capitulation of the towns of Erfurt (October 15th, 1806) and Magdeburg (November 11th, 1806) in which 23,000 prisoners were taken and 800 pieces of cannon fell into his hands. In the passage of the Taunus, the total destruction of a Prussian corps at Deppen (February 6th, 1807), the combat of Schomditten, by which the retreat of the Russians on Königscburg was cut off, and, finally, the defeat of the left wing of the enemy at the battle of Friedland (Bonaparte P.C.), which more than any other movement contributed to the victory. In September, 1808, he was appointed to command the army in Spain, and his distinguished services in the various engagements by which Galicia and the Asturias were subdued. In Portugal, though under the orders of Marshal Masséna, the merit of the capture of Ciudad-Rodrigo (July 10th, 1810) and of Almeida (August 27th, 1810) have generally been attributed to him. He was also of great assistance to Masséna in conducting his skilful retreat, after his failure in attempting to force the lines of Torres Vedras. (Masséna, P.C.S.)

The different dispositions however of these two great generals soon brought on differences of opinion, which ended in a serious dispute. The result was unfavourable to Ney, who was deprived by Napoleon of his command and recalled to France.

1813 found him engaged on the disastrous expedition to Russia, and had the command of the third corps of the grand army. In the course of it he appears to have freely expressed to Napoleon his dissatisfaction at some of his movements, and advised him to settle these matters. At the beginning of this year (August 17th, 1812), at the battle of Valentinia (August 19th), and, above all, at the sanguinary battle of the Moskva (September 14th), from which he derived the title of Prince of the Moskva, he eminently proved himself worthy of the surname by which he was known to the army, of 'Bravest of the Brave.'

But it was during the calamitous retreat of the French army that he rendered it the most important service. The details of it are amply described in the histories of Ségur, Chambray, and Labanne; the first of these, however, though one of the finest models of historical style, should be read in conjunction with the Memoirs of General Gourgaud, who, with military bluntness, and perhaps some personal hostility,corrects several erroneous statements of Ségur. One incident in this retreat is particularly characteristic of Ney's perseverance. General Dunns relates that as he was sitting down to breakfast at Ganbinne, a man in a brown coat, long beard, and a weather-beaten countenance, entered his room, exacted a passport, and said: 'Can you recognize me?' The general having answered that he did not; 'I am the rear-guard of the grand army,' he continued; 'I have fired the last musket-shot on the bridge of Kowno; I have thrown over the two lines of the Nereides, and I am now here through the woods. I am Marshal Ney.' (Colonel Mitchell's 'Fall of Napoleon,' vol. ii.)

In the campaign of 1815 Ney displayed his usual courage and perseverance. The following extract from the memoirs of one of his subordinates, Camp de Lützen, Lützen, and Dresden. He met however with some severe reverses, and at the battle of Dannewitz (September 6th, 1813) he was signally defeated by the Prussians and Swedes under Bernadotte, then Crown Prince of Sweden [The battle of Dannewitz was fought on September 6, 1813, in which the French were decisively defeated by the combined forces of the Russian, Austrian, and Saxon armies under the leadership of Prince Frederick Charles of Hanover, the Crown Prince of Sweden. This defeat marked a significant turning point in the Napoleonic Wars.], and a considerable number of his troops, about four thousand men, forty-three pieces of cannon, and three standards. After this disastrous engagement Napoleon had an interview with Ney's aide-de-camp, whom he interrogated respecting the conduct of the battle, and particularly in regard to the placing of his men. The latter attributed the failure to it to the generals present, without giving expression to any feeling of dissatisfaction at the conduct of his lieutenant. The Emperor," says St.-Cyr, who is quoted by Alison (Hist. Europe, vol. vii. p. 444), "explained satisfactorily the causes of the reverse, but without the slightest expression of ill-humour, or any manifestation of displeasure at Ney or any of the generals engaged. He ascribed the whole to the difficulties of the art of war, which he said were far from being generally known. He added that, one day or other, if he had time, he would write a book in which he would demonstrate his principles in a manner so precise they should be within the reach of all men, and enable them to learn the art of war as they learn any other science.'

After the abdication of Napoleon, in 1814, Ney withdrew from public life and retired to his chateau in Lorraine. It was there that, on the 6th of March, 1816, he received orders from the Minister of War to join the eighth military division, of which he was commander, and which was stationed at Basle. He immediately proceeded to Paris, where for the first time he learned the return of Napoleon from Elba. He then willingly undertook the duty which had been imposed upon him to lend his aid to the restoration of his master; and on taking leave of Louis XVIII., he assured him that he would bring back Bonaparte in an iron cage. As some doubts have been cast upon the truth of this boastful assertion of Ney, it may be well to state that he himself acknowledged on his trial that he used the expression. On leaving the king he travelled rapidly to Aixerre, where he alighted at the residence of his brother-in-law, the prefect of the department, who had zealously espoused the cause of the restored Napoleon. Ney acquainted with all the difficulties likely to attend any support of the Bourbon dynasty, and his own doubts on this subject increased as, advancing towards Lyon, he became more aware of the popular feeling in that part of France. The character of Ney was more fitted for the field of battle than for a political struggle, and it was only in the presence of danger that he showed resolution. Of this Napoleon was well aware, and he skilfully threw the weight of his influence and entreaties into the balance of Ney's already vacillating opinions. An earnest appeal to the early and glorious reminiscences of the prosperous days of the Empire, coming from his ancient chief, the creator of his fortune, and completely overawing him, was the result of this marshal. 'In the night of the 13th of March,' said he at his trial, 'down to which time I solemnly declare my fidelity, I received a proclamation drawn by Napoleon, which I signed. On the 15th of March, I was on my way to the troops, who received it with the most enthusiastic approbation.' His defection was speedily followed by that of his whole staff. On the 10th of June he joined the army at Lille, and was soon actively but unsuccessfully engaged with the British at Quatre-Bras. His conduct at Waterloo elicited equal praise both from friend and foe. His fruitless but resolute attempts at the head of the columns of the guard to overwhelm the British before they could receive succour from the Prussians, are well known. Five horses were shot under him in this terrible conflict; still, on foot, his clothes pierced with balls, he gallantly headed the impetuous charge. In the disastrous retreat which ensued, he was among the last to leave the field, and, as on the plains of Russia, he was the rear-guard of the last Imperial troops. After the defeat of Napoleon at Waterloo, Ney returned to Paris, and remained there after the capitulation of that city to the allies, considering himself safe by virtue of the twelfth article of the Convention. His advice was promptly rejected. The clause: 'All the individuals who are at present in the capital, shall continue to enjoy their rights and liberties, without being disquieted or prosecuted in any respect, in regard to the functions they have discharged, or have contributed to the political conduct or opinions.' (Convention, 7th July, 1815.)

On the 24th of July however appeared a Royal ordinance, in which, among several others, he found himself proscribed as a traitor. He had gained by obtaining the victories of Bautzen, Lützen, and Dresden; he met however
the château of Bessons near Aurillac. He was at first convicted before a council of war, which declared its incompetency to sit in judgment on a peer of France. His trial was then removed to the Chamber of Peers by another Royal ordinance of 29th July. His defence was most ably conducted by his eloquent advocates, Berryer and Dupin, and chiefly rested on the article of the capitulation above alluded to. The result however was that he was found guilty, and condemned to death. When the sentence was pronounced, Berryer ex- ployed Michael Ney, now a French soldier, and soon about to be a heap of dust.' A spot in the garden of the Luxembourg was selected for the execution; he met his fate at eight o'clock in the morning with calm courage. 'He who had fought five hundred battles for France—not one against her— was shot as a traitor.' (Napier, Hist. of the Peninsular War, vol. ii. pp. 406.)

The reflections of Alison on this event are creditable alike to his impartiality as an historian and his feelings as a man. 'The death of Ney,' he says, 'is a subject which the English historian cannot discuss without painful feelings. His guilt was so great; his past conduct so damnable; and his death inflicted upon one for a political offence who more richly deserved his fate. The question of difficulty is, whether or not he was protected by the capitulation of Paris. The clauses in that instrument clearly declared that no person should be molested for his political opinions or conduct during the Hundred Days; and it is very difficult to see how this clause was in any way to apply to a man who was within the city at the time of the treaty. Wellington and Büchler concluded the capitulation: their Sovereigns ratified it: Louis XVIII. took benefit from it. How then can it be said that he, as the allied sovereigns, were not bound by the treaty, especially in so vital and irreparable a matter as human life—and that the life of such a man as Marshal Ney? It is very true a great example was required; true, Ney's treason was beyond that of a man; true, the Revolutionists required to be shown that government could punish; but all that will not justify the breach of a capitulation. To say that Louis XVIII. was not bound by the capitulation; that it was made by the English general without his authority; and that no foreign officer could tie up the hands of an independent sovereign, is a quibble unworthy of a generous mind, and which it is the duty of the historian invariably to condemn. This was what Nelson said at Naples, and what Schwanzen- burg said at Dresden; and subsequent times have unanimously condemned the violation of these two capitulations. Banished from France, with his double treason afloat to his forehead, Ney, the great favourite of the Egyptian tide, felt as much as the world his guilt will be forgotten in the tragic interest and noble heroism of his death.' (Hist. of Europe, vol. x. p. 97)—

(For the following works we must consult for a full detail of the life of Marshal Ney: Vie du Maréchal Ney, avec Hist. de son Procès, Paris, 1816; Biog. des Généraux Français, par Courcelles; Hist. de Napoléon et de la Grande Armée, par Segur; Hist. de l'Expedition de Russie, par Chambray; Alison, Hist. de l'Europe, vols. iii. iv. v. vi. x.; Court and Camp of Napoleon; Mémoires de Rapp; Napier, Hist. of the Peninsular War; Mitchell, Fall of Napoléon; Examen critique de l'Hist. de Séguir, par le Gén. Gourgaud. The arguments in favour of his condemnation may be seen in the works of Bellart, the crown prosecutor, Affaire du Maréchal Ney."

RIBELIEN LIED. [GERMANY, P. C., p. 194.]

NICERON, JEAN-PIERRE, was born at Paris in 1685. He entered the regular order of Barnabites, and de- voted himself to the study of languages and biography. He led a life without incident, and died at Paris on the 8th July 1738. He is chiefly known as the author—or in some parts rather the compiler—of Mémories pour servir à l'Histoire des Hommes Illustres dans la République des Lettres, of which thirty-nine volumes were published by Niceron, and four were added after his death. All who have had occasion to study the earlier literary history of France must be under obligations to the worthies of which Niceron's Mémories are never very high in criticism, philosophy, or the essential elements of spirited and descriptive biography. Niceron was however a curious and laborious reader, and in those instances where he exhibits the fruit of his own original re-

search, his matter is highly valuable. Many of the lives however are mere compilations from other sources, and appear to have been hastily prepared to suit the order of publication. There is little attempt at a proportional distribution of space, seldom is a writer treated with any grace or consideration, and he stands out as elaborate as the most distinguished men of their age. This is a defect sometimes not unpleasing, as it generally att-
for it reconciles all the facts recorded of Nicias, and it is much more probable that Praxiteles would employ a young man to colorize and give him his passion, than a great painter, his equal in age and reputation. Statue-painters, *χρώματος χρωστοί*, constituted apparently a class of themselves, and Nicias may have been one of these in his youth. It is more probable that one of his greatest painters of his time should be thus employed. One of Sill's difficulties in identifying these two as one, is, that Nicias was the pupil of the pupil of Empourhor, who was the contemporary of the great painter. It is true, however, to suppose that there must necessarily be a generation between master and pupil: the master is frequently only a very few years older than his pupil, and is sometimes even younger. If we suppose that Empourhor was a generation younger than Praxiteles, there is not the slightest difficulty in the way of his having been the pupil of the pupil of a contemporary of Praxiteles.

Nicias painted in encaustic, and besides the one already mentioned Pliny notices the following pictures by him:—an Alexander (Paris), a sitting Calypso, an Io, an Andromeda, and another Calypso, in the hall of Pompey; a Bacchus, a Diana, and a Hyacinthus, in the temple of Concord. The Hyacinthus was brought to Rome by Augustus from Alexandria, and was consecrated afterwards by Tiberius in the temple of Augustus, on account of his great delight in it: it is mentioned by the Roman authors (III. 19), who says that the figure of Hyacinthus was very elegant. Augustus dedicated and fixed in the wall also a picture by Nicias in the Curia Julia, of Nemos sitting on a lion, holding in his left hand a serpent, which was fastened to his gown by a small bow; that was the picture of an old man, resting upon his staff; above him was hanging a picture of a Biga. It was brought from Asia by Silanus, and was most probably the same of which a Teutons was ambiguously being asked his opinion, said, according to Pliny, 'That he would not have him even if he were real and living,' alluding to the old man with his staff: entirely overlooking the art which embellished the picture, and measuring the man apparently by his sinew. Leucippus (Lacocon, p. 380, note) proposes to substitute in the place of the picture of the Biga, (tabula biga) hanging above the man's head, which he supposes to be a corruption of the text, a name tablet, called by the Greeks *στυλίων*. Nicias wrote on this picture that he had burnt it in, *Nicis θεσσαλικος*, that it was painted in encaustic. These words were, in the opinion of Leucippus, written upon the small painted tablet which was hanging over the head of the old man—*cuio supra caput tabula biga dependit*. Nicias scriptum se insensi; tali enim uasis est verbo. The passage is obscure; only one picture is spoken of; the words *tabula biga* may be corrupt; it is certainly difficult to give them a suitable meaning. The Biga, says Leucippus, can have no respect to the Nemean games, because in them four-horse chariots were used. (Schmidius, in Pro. ad Nemeonicae, p. 2.)

The pictures of the interiors of houses of that of Merga-byzus, high priest of Ephesus, and one at Triaeum. Pausanias says, before you come to Triaeum from Phare there was a *σεπχυρε* of white marble, which was particularly worthy of inspection on account of the painting thereon. A beautiful young woman was represented seated on an ivory chair, and behind her was a female servant holding an umbrel; a beardless youth also was standing near her, dressed in purple; by the youth was an attendant with hunting spears and a leash of dogs (Nicias was, according to Pausanias, the most excellent animal painter of his time); the names of these people were not known: Pausanias supposed them to be man and wife. Nicias was honored with a public burial, and was interred in the road from Athens to the Academy, the cemetery of all great Athenians: Pausanias notices his tomb there. He appears to have been a very statesman. Athenae says he used to forget to take his meals (Var. Hist., iii. 31).

It has been said above that Nicias painted some of the statues of Praxiteles: this requires some explanation. Pliny relates that Praxiteles being asked which of his marble statues he preferred, answered, 'those which Nicias had had in hand; so much did he attribute to his color.' As this word *circumlitos* has been variously interpreted: Fuuci supposed it signified the outlining of the clay model; but Pliny is speaking of marble statues, and the circumlitos must have been some superficial applications. If this be applied to a color question is also about a process which the marble statues have undergone at the hands of a painter. Cicero has 'Persae

mortonis eura circumlitos condunt.' (In Tusc., i. 45.) There is a prejudice against the idea that the Greeks painted their marble statues; but to some extent this is true, in fact, though it was not a universal practice. The statue-painters, of *χρωστοί* or *χρώματος χρωστοί*, as Plato calls them, are definitely spoken of by Plutarch (De Glor. Athen., 6), as *χρωστοί*, or *χρωστοί*, as *χρωστοί*. Statues seem to have been sometimes entirely painted, which appears from the following words of Plato (De Republ., iv. 420. c.). He observes, in speaking of the dispute about the statue painting, 'Every one of them assumes that the color shall be accorded to any particular part, but by giving every part its local colour, that the whole is made beautiful.' That it was not however the common practice to paint the marble entirely in color is evident from the correspondence between Lycurgus and Aristar tus, in the dialogue of the Portrait, or Pauhena, in Locius; from which it is plain the Venus of Cnidus, by Praxiteles, and other celebrated statues, were not painted, though parts may have been coloured, and the whole body covered with an encaustic varnish. (Locius, Imag., 5-8.)

We may infer therefore in this case that the *circumlitos* of Nicias, applied to the marble statues of Praxiteles, was the *χρωστοί* of Plutarch, and that Nicias was himself an *ακρωτήριον χρωστοί*, or painter of statues, in his youth. In his *circumlitos* the naked form was probably merely varnished, the colouring being applied only to the eyes, eye-brows and other noticeable parts, to increase the effect of the draperies, and to give a more finished effect to the whole; and there can be little doubt that marble statues, especially of females, must have had a very beautiful appearance when carefully coloured in this way. (See his *Roman Antiquities*, Art Painting, by the author of this article; Pliny, Hist. Nat., xiv., 10, 36-40; Pausanias, i. 29, iii. 17, vi. 22; Plutarch, More, 11; Junius, Catalogue Artificum.)

NICOLE, PIERRE, one of the distinguished painters of Port Royal, was born at Chartres on the 19th of October, 1625. At the age of fourteen, when he is said to have had an ample command over Greek and Latin, he was sent to study at Paris, where he was persuaded to join the community of the Port Royal. There he occupied himself in instructing the pupils confided to the institution. He formed an intimate acquaintance and a species of alliance with Anthony Arnauld, with whom his zeal and restless energy his placid disposition and clear systematic mind afforded a strong contrast. (Amsbach, F. C.) The angry disputes regarding the five points of the Jansenists prompted him to remain for several years a simple clerk, but in 1676 he was induced to seek holy orders. He was refused the necessary consent however of the Bishop of Chartres, who disliked his opinions; and he was evidently rather rejoiced than saddened by an excuse for remaining in a position where he was not too near the van in the battle of controversy. In his own province, however, of a clerical or polemical logician, he was bold and uncompromising, and was regarded by the Jansenists as too conspicuous a championship that he shrunk. He was obliged in 1679 to retire from France, but returning soon afterwards, he entered with some keenness into two of the most celebrated disputes of the age. He went to the monastic institutions, where he joined Mabillon in defending a devotion to science and learning in place of pure asceticism; and the discussion regarding quietism, in which he opposed the devotees of that mental epidemic. He was a man of simple habits and candid mind, and some ludicrous incidents have been told as arising out of his absent habits. He died on the 11th November, 1686. His works are many and voluminous. He was the principal author of 'La Logique, ou l'Art de penser' (1658), known as the Port Royal Logic. Of the first three volumes of 'La Perpétuité de la Foi de l'Eglise Catholique touchant l'Eucharistie,' which is generally associated with his name of Arnauld, he is known to have been the principal writer. Hume admired the logical clearness with which Nicole in this work showed the impossibility of one mind sufficiently examining all objects connected with religion to form a creed for itself on the principle of private judgment; and stated that the difficulty so ingeniously set forth suggested to him the sceptical argument in his Dialogue with a Naturalist. He wrote also 'Traité de l'Unité de l'Eglise'; 'Les Prétendus Réformés convaincus de Schisme'; 'Les Lettres imaginaires et visionnaires,' &c. He was eminent as a translator and composer in Latin, and in 1656 published a translation of Ibsen's 'Historie.'

(Niceron, Mémoires, t. xxiii. 285-333; Nouv. Dictionnaire Historique.)
Nigell, Robert, a poet distinguished by the precocity of his talents, was born at Tulybelfane, in Perthshire, on the 7th January, 1814. His parents were in too humble circumstances to afford him any education beyond the rudiments of reading and writing; and at a very early age he was set to the occupation of herding cattle. At the age of seven he was apprenticed to a grocer in Perth, and at the conclusion of his service endeavoured to earn a livelihood by keeping a circulating library. In the midst of this occupation he had been acquiring the elements of knowledge. He was a devourer of books, and at the age of twenty had acquired both knowledge and cultivation without being educated. In 1834 he published a collection of Poems, which became very popular, were extensively noticed by the newspaper press, and passed through three editions. They are less remarkable for energy or originality than the fruit of a fine-toned and sensitive mind. In prose his writing was of a different character. In 1836 he undertook the editorship of the 'Leeds Times,' a paper of strongly liberal sentiments; and by the energy and vigour of his political articles, and their association to the feelings of the surrounding community, he soon more than tripled the circulation of the paper. His early struggles had probably undermined his constitution, and he soon sank under the exactitude of his editorial labours. When on his death-bed he was removed to the neighbourhood of Edinburgh, where, amidst the attentions of kind friends, he died on the 9th of December, 1837, in his twenty-sixth year. 

(Memoir, by Mrs. Johnstone, prefixed to a third edition of his Poems; Westminster Review, No. 76.)

Nicomachus (Nicasouydis) of Thessalonica, son and pupil of Apelles of Alexandria, flourished between 360 and 300 B.C. He is classed by Cicero with Apelles and Protagenes, and his paintings are compared by Plutarch with the lines of Homer: he was the most celebrated of all the Greek painters for rapidity of execution. In illustration of the rapidity of his execution, Pliny mentions the decorations of the monument which Aristratus, tyrant of Sicyon, had erected in honour of the poet Telestes, which were executed in a few days. In one of his works, which was reserved for the beauty of the whole, to the entire satisfaction of Aristratus, who shortly before was exceedingly angry with him, for, as he supposed, neglecting his contract, which was to have the tomb finished by a certain day. Nicomachus had deferred the commencement of the tomb so long, that Aristratus concluded he did not intend to meet his engagement; the painter, however, was a better judge of the required time in his own case. The notices of Nicomachus are few, and what there are contain but little information about him. Pliny mentions by him—A R ape of Proserpine in the Temple of Minerva on the Capitol, hanging above the niche or shrine of Juno or your. In the description, the face is fresh which is dedicated by Pianus: also Apollo and Diana: a Cybele, the mother of the gods, sitting upon a Lion; Bécantes, with St. John breathing up to them; and a Scylla, which was in the Temple of Apollo on the Tiber, and is now seen in the painting of the Tyndarides by Nicomachus; he instances it as an example of the unfinished works of painters being in greater request than well-executed works, which left unfinished through death, or perhaps other circumstances impeding their completion: he mentions four pictures—the Tyndarides of Nicomachus, the Iris of Ariadne, the Medea of Timotheus, and a Venus of Apelles. Nicomachus is the first who represented Ulysses with the pike or cap of liberty. He is one of the painters from whom an error of Pliny's is said to have used only four colours. (See Dictionary of Greek and Roman Art, by Percival, p. 147.)

N. sativa has ovate obtuse anthers, capsules muriarated, united to the very point into an ovate fruit, terminated by five erect styles; the stem erect and rather hairy; flowers naked. The seeds are eaten in the same way as the former are used instead of pepper; and have also been employed as carminatives. It is the Melandrium of Hippocrates. 

Steril. 675, and of Dioscorides, 3, 93; the Gibex of Pliny, 20, 17.

N. aromatica has pointed anthers; from 5 to 7 styles ciliate, involute, downward smooth; capsules connected below the middle into an obconical fruit, which is narrowest at the base. It has a smooth stem, with diverging branches. It is native of middle and southern Europe in corn-fields, also in the north of Africa. The seeds are sometimes used instead of those of N. sativa, but they are not so aromatic, neither have they so pleasant a smell. Both species are employed in the adulteration of pepper. All the species of Nicella are plants of easy culture, only requiring to be sown in the open border. They are hardy and annual plants.

(Don, Gardeners's Dictionary: Lindley, Flora Medica; Frass, Synopsis Plantarum; Flora Classic.)

NIGRIATA is a term, which was formerly applied by geographers to the black African, and was derived from the name of Sooan of which Arabic expression it is only a translation, meaning the country of the blacks. (Sooan, P. C., vol. xii.)

NILE. Since the article Nile was printed in the P.C. the course of the western branch of the river, the Baher-el-Abiad, has been traced to 4° 42' N. lat., which is nearly nine degrees south of Aleis, to which place it had been explored by Linnant. It ascends in the year 1840, 1841, 1842, 1843, and in the year 1845, the pasha of Alexandria made preparations for the purpose of exploring the course of the river to its source, and the two last expeditions were accompanied by several scientific Europeans. South of Khartoum (15° 17' N. lat.) and as far south as Aleis the Baher-el-Abiad is in general from one to two miles wide, and runs in a bottom, which is generally four miles wide, but sometimes even six miles. The bottom is covered with grass and the higher grounds at the back are partly covered with trees. There occur a few low hills in this part of the country. The western banks of the river are occupied by the Husunnyé, a nomadic tribe of Arabin origin, the most southern of this division is a Vataya, which closes the west side of the river, and are frequently several miles long and a quarter of a mile wide, and nearly all of them overgrown with high trees and bushes. On the western side is a mountain group, called Arassali, which is crowned with seven peaks; between this high ground and the banks of the river are extensive forests. In these forests are numerous villages, which when seen from the river appear to be regularly arranged in three rows parallel to the river. They are inhabited by the Shillucks, a paitical nation of blacks, who frequently descend with their boats in great numbers to the countries lower down the river, and formerly extended their incursions as far as Khartoum, where at present they are kept in awe by the pasha of Egypt. Near the southern limits of their territories the country is interspersed with numerous isolated conical hills, among which one called Déva Fungh (10° 90' N. lat.) stands out, which itself rises from a flat volcanic cones, consisting partly of tuff and red-brown porous lava.

Near 9° 11' the Baher-el-Abiad is joined from the east by a large tributary, the Sobat, which is supposed to rise in the higher mountains of Abyssinia, and which is nearly equal to that of the principal river. The lower course of this tributary was explored, and it was found that it runs between banks, which are much higher than those of the Baher-el-Abiad, and as far as Khartoum, from the mouth of this river to Khartoum the Baher-el-Abiad flows from north to south, but higher up it runs from west to east for about a hundred miles, through a country inhabited by another black nation, the Dinkas, who are divided.
Into seven tribes and speak a language different from that of the Shillucks. In this part (between 8° and 9° N. lat.) the river appears to traverse an immense swamp interspersed with many smaller and larger lakes, one of which is stated to cover an area of 420 square miles. A broad, sluggish river runs through these low grounds is imperceptible, and its water divided into so many branches, that it is difficult to find out the main channel. It is supposed that the great quantity of water which runs through the different parts is brought by a river running from north-west to south-east, perhaps that river which by the Arabian geographers is called Kailisec. It is also possible that the course of this river has induced them to adopt the ostrich-skin for the reasons of clothing, which they wear, and in this part. The Nuba inhabiting this swampy region are a nomadic tribe, who live principally on the produce of their herds of cattle, distinguished by large horns like those of ancient Egypt. They are less strongly built than their northern neighbours, the Shillucks, and it appears that their health suffers from their residence in the swamps. In this region the elephants, giraffes, and hippopotami are met with in great numbers.

Before the Bahr-el-Abiad enters this swampy region it runs from south to north, but farther upwards (south of 7° N. lat.) from south-east to north-west. The country traversed by it is a plain. They are completely navigable, without channels, and even without rapids. Its eastern banks are occupied by the Nuerres, and its western by the Kyks or Kekos. Both nations are cultivators of the ground, but have also numerous herds of cattle. They are not very numerous. The colour of their skin inclines to the red, and their hair is smooth and lank, not woolly. They have enclosures round their huts, and others for their cattle. The Kyks have also numerous wells for water, but live entirely on cattle and roots. Both nations received the expeditions with confidence and joy, and presented to them a great number of cattle. It appears that these tribes speak a language which is understood by the Dinkas.

Farther upwards other tribes are named, as the Helibah, Bhor, and Chir. At last the expeditions arrived in the country of a black nation called the Barrys, where their progress was stopped by the gibbons which inhabit the river banks at its width near 4° 42' N. lat. and 30° 58' E. in. Long. In approaching 5° the bed of the river, which up to these parts appears to be formed by alluvial soil, begins to be rocky, and at the same time mountains become visible, which extend from east to west. The river by degrees acquires such a velocity as to run six knots an hour. According to the information obtained from the aborigines, or king of the Barrys, persons must walk for a month before they arrive at a country called Anayas, where the river is formed by the confluence of four rivulets, the largest of which comes down from the east.

The Barrys are described as a very warlike nation. They can cook five things at once, and speak a peculiar language. Their country is well cultivated and exhibits the richest crops, their fields being irrigated by numerous canals. They enjoy a considerable degree of independence and are armed to the teeth. They are also acquainted with the art of tanning and making some cotton fabrics, and wearing copper and ivory, which they employ as ornaments. The king is said to live in a palace, built on an island, to which his subjects can only arrive by swimming. He is surrounded by a guard composed of women. It was observed by the persons who composed the expedition, that the inhabitants were in possession of several articles which are not to be found in India, or in the countries at the extremity of the East Indies, as several pieces of damask made at Surat, as also swords and other arms of iron. They are also acquainted with a system of wood and ivory, which they employ as ornaments. The king is said to live in a palace, built on an island, to which his subjects can only arrive by swimming. He is surrounded by a guard composed of women. It was observed by the persons who composed the expedition, that the inhabitants were in possession of several articles which are not to be found in India, or in the countries at the extremity of the East Indies, as several pieces of damask made at Surat, as also swords and other arms of iron. The natives stated that all these articles were brought to them from a commercial place which they called Barry, and which, as they say, lies journey farther east, at the foot of a range of mountains.

Thus we learn to account for these expeditions that the interior of Africa is much more populous than was supposed, and that several of the nations inhabiting it have attained a considerable degree of civilization.

NIMA. A genus of plants belonging to the natural order Simaroubaceae, of dry localities in some parts of the world. The plants have permanent calyx, 5 oblong petals, 5 stamens with filaments dilated at the base; the 5 ovaries are connected together, pilose, and seated on the thick disk beneath the ovary. The flowers are dioecious. The fruit is a small, dry, box-like capsule, from which the petals are, with alternate imparipinnate leaves, having four pairs of serrated leaflets. The flowers are disposed in paniculate corymbs.

N. quadracis is a native of Nepal, in a valley near the town called Thankot. It has elliptical oblong leaves, which are acuminate and serrated. The coryms are trichotomous. It is as bitter as the quassia of South America.

(Don, Gardner's Dictionary; Lindsey, Flora Medica.)

NINEVEH. Since the publication of the article NINEVEH in the 'Penny Cyclopedia,' discoveries of the highest importance have been made, if not on the precise site, yet in the immediate vicinity of it. The following are some of the most interesting particulars.

For these discoveries we are indebted to M. Botta, consul of France at Mosul on the Tigris, opposite to the presumed city of Nineveh. He was visited by his Excellency in 1843, announced to his friends his intention of employing what leisure the duties of his office might allow him in making excavations at Nineveh. He began with some operations in the immediate vicinity, but having been prevented from proceeding beyond the Daben, it was not until the spring of 1845 that he was enabled to proceed to the Guara, and Nineveh, however, to the excavations of the city. Here we look to the Assyrians for the symbols of those ancient times. It is ascertained that Nineveh was the residence of the kings of the Assyrians, and the seat of their government. It is stated that the city contained upwards of 100,000 inhabitants, and was surrounded by a wall of great strength.

M. Botta, the name, which is certainly not Arabic, is pronounced in all these ways), distant about five hours (caravan reckoning) north-east of Mosul, on the left bank of the little river called the Khaiser (Khosor). M. Botta's researches in this place not only proved more successful, but have led to discoveries of the highest importance, which, if the numerous cuneiform inscriptions can be deciphered, will doubtless throw great light on the ancient history of Asia. Commencing his excavations in a small mound, his workmen soon came to a monument, remarkable for the number and style of the sculptures with which it is adorned. About ten acres of ground have been excavated by M. Botta regularly communicated, during the progress of the work, with M. Julius Mohl, at Paris, to whom he wrote sixty letters, with drawings of the sculptures and copies of the most interesting inscriptions, and the drawings and inscriptions, in the 'Journal Asiatique,' and they have since appeared in one volume, with fifty-five plates. M. Botta regretted that he was not a competent draughtsman, and wished the government to send him a good artist; and as soon as the French ministry were aware of the great importance of the discoveries, they sent him M. Flandin, an able artist, who had lately returned from Persia, and granted sums of money to enable M. Botta to prosecute his researches. The following particulars are extracted from M. Botta's letters, and such parts have been selected as may be understood without the plates. Great quantities of inscriptions were thrown in his way by the ill-will of Mehemet, the Pasha of Mosul. All are now happily surmounted, and the excavations are terminated (in 1845). M. Flandin has
returned, with drawings of 130 bas-reliefs; and the greater part of the sculptures (weighing it is said above 300 tons) have been sent to Bagdad, to be embarked on board a vessel to sail for your port, under the orders of the Viceroy of Egypt; and the great number of the bas-reliefs has been deposited in the Egyptian museum. M. Botta is we believe now at Paris, with copies of 200 inscriptions, and will publish an account of his great discoveries, with engravings of all the sculptures and inscriptions he has collected.

From M. Botta's third letter, dated Momb, June 2nd, 1843.——I return with increasing astonishment from my discoveries at Chersâbâb. My operations have again brought to light the remains of one of the robenos of the temple. On the south, the north wall of the apartment there are, first, some figures of, which only the foot remain; then a bas-relief, on which there are two archers standing and two kneeling, who wear coats of mail, and have an inscription over them. These archers are shooting at a fortress, which is taken by storm. The fortress consists of an embattled wall, strengthened by projecting towers; at the bottom there are undulating lines, probably representing a river or the water of the moat. Within this wall there is an eminence with a castle upon it, from which arise what I suppose, from their red colour, to be intended to represent flames. At the other extremity there are three warriors armed with pikes, holding their shields over their heads, and ascending a ladder; others have already reached the top; and in the intervals between the towers others are mounting scaling ladders. At the other extremity and these are partly damaged; we only see that one of the soldiers pursues an enemy with his sword; a man pierced with an arrow is seen falling from the top of the wall and is cut off. The fortresses others are lifting their hands to heaven; at the bottom there is a row of wretches impaled. On the top of the hill there is a short inscription, probably containing the name of the fortress. The whole is very animated.

The attitudes are perfect, and though the heads of the figures are scarcely an inch long, the expression of the features is excellent.

After this bas-relief there are on the same wall five war-chariots following each other, turned to the fortress, and evidently meant to represent a battle. These chariots are all alike. The horses are in full gallop, and trample with their hoofs on a man lying on the ground. There are five persons in each. The principal figure wears a pointed, turban, and is discharging arrows; beside him is the driver, and behind them two warriors, armed with darts and wearing bucklers. Above there is a man who seems to be wounded, and thrown into the air with the head downward. The singular position of this figure is perhaps meant to indicate the confusion of the battle, or the rapidity of the chariot, which violently throws to one side those that are behind, so that the rear is extremely animated; the horses are particular in very spirited. The harness of the horses is very rich, and has evidently been coloured. These five bas-reliefs are each seven feet from the top of the wall; and on several parts of the foot of the wall there is a long inscription, which at first seems to be continuous, but it is certain that it is divided into parts, each bounded by the edge of the slab on which it is sculptured. Each line of inscription which separates the inscriptions, which differ in the number of lines.

M. Botta describes several other figures, and proceeds——

'This description of these newly discovered sculptures is very incomplete; to describe them in detail would require a volume. I doubt whether more richly decorated walls are to be found even in Egypt. In the whole monument there is scarcely a square foot which is not covered with sculptures and inscriptions. The mode of building is everywhere the same. The walls are formed of enormous slabs of gypsum or alabaster ten or twelve square feet, and scarcely a foot thick. These slabs are laid smooth and level, thicker than in Greek sculpture, but higher than the Egyptian. Though rather stiff they are well designed, the attitudes admirable, the muscles strongly marked, and the hands, feet, and dresses of the figures carefully modelled. The face isI	stated some particulars which may aid them in their researches. Though the hair, the beard, and the costumes resemble the Sasanian modes, I have found no trace of any inscription in a different character. I found on the monument itself: all the mythological emblems are Babylonian. I have not met with any trace of iron being employed in the monument, but many remains of articles of copper (quiver brass or bronze); nails, rings, and other ornaments of gold or jade, of a foot and a half in diameter. These facts indicate the antiquity of the monument; but on the other hand I have discovered that the stones with which it is built belong to a more ancient edifice. In fact, on my way to the temple I have on the back cuneiform inscriptions evidently injured by time, in characters exactly resembling those on the present monument.'

M. Botta in his fourth and fifth letter continues to give an account of the progress of his discoveries; among the most interesting are two colossal statues of bulls fifteen feet high, with human heads, and between them a passage seven feet and a half wide, forming, as he presumes, a portal of a striking character and of great magnificence. These bulls were winged; they are not proper statues, but in high relief. On clearing the passage it was found that the bodies of the bulls were continued on the walls in low relief. These figures are of large dimensions, 18 feet in length and in proportion. They have five legs, so contrived that from whatever side you look at them, one leg being hid by another, four legs are always to be seen. On each side of the passage is this inscription: the entrance, there is a figure with the head of a bird of prey; the hair is regularly braided, on the head is a sort of cap which comes down over the chest. The figure has a necklace, armlets, and bracelets, and wears a short tunic with a fringe girdle. On the opposite side of the chamber, M. Botta afterwards found a similar portal. M. Botta resolved to send two of these bulls to Paris.

This discovery cannot fail to engage the attention of the learned; but unfortunately the greater part of these remains has already disappeared. The walls are not solid, but formed of slabs of gypsum or alabaster, with an intervening space which is filled up with earth. 'This earth,' says M. Botta, 'has caused the walls to bulge in many places, and broken the sculptures into a thousand fragments since I have cleared them. Having nothing to support them, they would fall did I not take the precaution to shore them up as I proceed; but as these supports will last only during the operations that I am carrying on, the monument will necessarily perish entirely if the enlightened munificence of the French government does not furnish me with means to save the most interesting portions.'

In a report to the Minister of the Interior, M. Botta says, "I have visited the temples of Khorsabad and Nineveh; the latter had been suspended for two months on account of the heat, a much regret that a great part of the sculptures is already destroyed. The inhabitants have stolen the props which I had placed to support them; the rapidity of the walls to fall. I am extremely sorry that M. Flandin has not yet arrived.'

'I am still in doubt," says M. Botta to M. Mohl, 'respecting the destination of this monument: whether it was a palace or a tomb. The latter seems the more probable, because the interior must have been completely dark; for there is no appearance whatever of windows. At all events, the extreme richness of the decorations, and the number of battles represented, prove that it must have been built by a rich and powerful monarch.'

'It is to be hoped that the 300 tons weight of the sculptures sent by M. Botta to France, the 200 inscriptions, and the drawings of M. Flandin, will enable the learned antiquaries of Europe to throw much light on the history of those remote ages.

The writer of a private letter from Constantinople says, "M. Flandin's drawings, which we had the good fortune to see a few days ago, will greatly interest the public in general as well as antiquarians—the manners and customs, the art of war, the religious, and the domestic life, and the art in general."

A letter from Constantinople, of the beginning of 1844, says, "M. Botta has entirely given up his opinion that the slabs had belonged to another building. The reason is, that the figures from the angle of all the sculptures, have the two forms forming the corners being cut out of one piece, and have always been found at the back, as if the walls had always been succeeded by those figures being so placed that they could never be seen while the building remained entire. These figures are represented in all manner of religious, or mystical manner, and were purposely concealed, like the column which M. Flandin found in deep recesso in the walls; which could not be got at so long as the wall remained entire."
who built Khorsabad, are here delineated in mitful copies of the bas-reliefs. The principal figure in most of them is a sovereign, king, or hero; on his head he wears the tiara, his forehead is bald, his cheeks and beard fall straight on the shoulders and breast, terminating in large ringlets. The dress, which appears to have been extremely magnificent, consists of a richly embroidered tunic of cloth of gold, from one shoulder supported by the surplice or chasuble of the Roman Catholic priest. This figure appears, sometimes engaged in combat, driving his enemies before him; sometimes seated at an entertainment; and sometimes in solemn procession. He is accompanied, as is usual, with four horses abreast. Among the many figures of combatants, there is frequently a shield-bearer, under whose protection another warrior draws his bow or poises his lance.—There are no female figures, except one, which is rude and unfinished. But first took several figures for females, but afterwards changed his opinion, and thought they might perhaps be meant for eunuchs.

(Lettres de M. Boite, sur ses Découvertes à Khorsabad près de Ninive, publiées par M. Julluis Molt, Paris, 1845.

NIPADITDES, a genus of fossil fruits, from Shoppey. (Bowerbank.)

N. tinctoria (in Law), P. C.)

NISSOLIA (in honor of William Nissole, a French botanist), a genus of plants belonging to the natural order Leguminosae. It has a campanulate calyx, a papillose corolla, and ten monadelphous stamens. The legume is stipitate-pedicellate. The species are climbing shrubs, with imparipinnate leaves.

N. ferruginea has from 7 to 11 leaflets, which are alternate, oblong, mucronate, and clothed with rusty velvety down; beneath they are coriaceous, with prominent nerves, and the legume straight and rather velvety. The flowers are violeous. It is native of Guinea, and exudes from its stem a red transparent gum that has a powerful astrangent flavour. It is also known by the name of N. quinquefaria. It ranges itself on the surface of the plate in a state of rest: these are called nodal lines, and the figures which they form are called Acoustic figures. Again, if a glass rod be cemented at one end to the centre of a disk of the pass material, and be controlled by being rubbed, for example, with a wet cloth, so as to be put in a state of vibration longitudinally, those vibrations will be communicated to the disk, and light dust stove over the latter when in a horizontal position will arrange itself in acoustic figures. Or, if a glass rod be connected at each extremity to a glass disk at right angles to its length, on exciting one of the disks by drawing a violin-bow across its edge, the vibrations of that disk will, by means of the rod, be communicated to the other; and if light dust be stove over both it will arrange itself in figures: when the disks are equal and similar to one another, the figures are the same on both; otherwise they are different.

If a column of air in a cylindrical tube which is closed at either, or at each end be acted upon by the force of the breath, for example, applied at an aperture in any part of its length; it will emit vibrations. It is the largest of the pipes of the British species, and best adapted for the examination of the curious currents, which are obvious in the whole of the family to which it belongs. [Sar, P.C.]

NITELLA, a stem one to six feet long, smooth, flaccid, somewhat glossy and pellicul. It is not unfrequent in lakes and still waters. The nucles are often solitary. The stem, like that of Chara, is often incrusted with carbonate of lime. Hassall thinks this constitutes the only distinction of Agardh's N. opaca.

N. nidificus, has single stems, smooth below, flaccid, somewhat glossy and pellicul: the nucles and globules separate. It is a native of the salt water ditches in the south and east of England.

N. gracilis has smooth, glossy, pellicul stems, with whorls of the branches compound, the segments acute, the bracts wanting, and the flowers small delicate and elegant species, but probably not distinct from N. flexilis. In fact, it may be questioned whether all these species are not varieties of one. (Hassall, Freshwater Algae: Smith, English Botany.)

NODAL POINTS AND LINES. The former are those points in the length of a string extended between two fixed objects, or in a column of air confined at one or at each extremity, which, when the string or column is put in a state of vibration, is restored at rest to the latter at rest, and the latter at rest, corresponding lines which exist on the surface of an elastic body, usually a plate, whose parts are in a state of vibration.

It is well known that if a string or a metallic cord be attached at its extremities to a board or plate, on causing it, when in a state of tension, to vibrate transversely, there may be distinguished, besides the principal sound, which is due to the length of the string, several others which have a greater or less degree of distinctness: they are considered as resulting from some property of the extended string, by which, when in a state of vibration, it becomes a sort of moving axis, having on it points, at distances from each other corresponding to the several degrees of flexibility in its different parts. The string between every two such points is in the same condition as if it were a line perpendicular to it. But first took several figures for females, but afterwards changed his opinion, and thought they might perhaps be meant for eunuchs.

A string of considerable length, on being made to vibrate, will be found to have several such nodal points, and the curves which the intervals assume in consequence of the vibrations, though alternately on opposite sides of the axis of the string, are equal and similar to one another. The situations of the nodal points may be made evident by placing, at intervals, across the string, pieces of paper notched or bent in the form of an inverted V, those which are at the places of the nodal points remaining stationary while the others experience considerable agitations, or are thrown entirely off.

If a string, in a state of tension, has its extremities attached to a board or a plate of metal, and be made in some part of its length to vibrate, it will be found that the board or plate, the vibrations of the string, when a violin-bow is drawn across it, will be communicated to the plate; and if over the latter light dust be stove, that dust will be agitated and made to arrange itself on the surface of the plate in a state of rest: these are called nodal lines, and the figures which they form are called Acoustic figures. Again, if a glass rod be cemented at one end to the centre of a disk of the pass material, and be controlled by being rubbed, for example, with a wet cloth, so as to be put in a state of vibration longitudinally, those vibrations will be communicated to the disk, and light dust stove over the latter when in a horizontal position will arrange itself in acoustic figures. Or, if a glass rod be connected at each extremity to a glass disk at right angles to its length, on exciting one of the disks by drawing a violin-bow across its edge, the vibrations of that disk will, by means of the rod, be communicated to the other; and if light dust be stove over both it will arrange itself in figures: when the disks are equal and similar to one another, the figures are the same on both; otherwise they are different. If a column of air in a cylindrical tube which is closed at either, or at each end be acted upon by the force of the breath, for example, applied at an aperture in any part of its length; it will emit vibrations. It is the largest of the pipes of the British species, and best adapted for the examination of the curious currents, which are obvious in the whole of the family to which it belongs. [Sar, P.C.]

These portions are separated from one another by sectional areas in which the particles are at rest: the condensations, or rarifications, of the air being affected, while, in the intervals, they will be greatly agitated. It, in the side of a tube containing a column of vibrating air, any aperture exist by which that air is enabled to communicate with the atmosphere, the air in that section becomes in equilibrio with the latter, and, in that section, there is consequently neither condensation nor rarefaction; this section corresponds to the middle points between two nodes in a vibrating string.

Vibrations corresponding to those which are produced in strings or rods and in columns of air may be conceived to take place in any solid bodies or in any elastic fluids whatever be the figure, and the latter at rest, the corresponding lines which exist on the surface of an elastic body, usually a plate, whose parts are in a state of vibration.

It is well known that if a string or a metallic cord be attached at its extremities to a board or plate, on causing it,
are found to take place parallel to the surface, and others perpendicular to it: the former being called tangential, and the latter normal vibrations. In one case the particles of dust glide upon the surface in directions which tend alternately towards and from the nodal lines (the movements in the former direction being always more rapid than those in the other) till they come to a state of rest on those lines: in the other case the particles alternately rise from and fall back upon the surface at the places where the latter is in a state of vibration; and, dispersing from those places, they become quiescent in the lines of no vibration.

Galileo was the first who observed (Dialogo delle Scienze Nuove) that the vibrations of plates might be rendered visible by covering the plates with fine sand; and he remarked that the sand became accumulated at the parts where the vibrating plate was in a state of rest: but this subject was extensively investigated by Dr. Chladni of Wurttemberg, who first discovered the longitudinal vibrations of solid bodies; and, in 1787, published, in a work entitled Entdeckungen über die Theorie des Klanges, an account of numerous experiments which he had made on the nature of the vibrations produced in plates of glass of different forms.

The plates with which such experiments may be performed should be of good window glass; and, if square, from 4 to 8 inches each side; if circular, their diameters may be within the same limits: in making an experiment the plate must be held horizontally between a finger and thumb, or it may be fixed within the lips of a clamp screw; and when it is required to prevent any particular part of the plate from vibrating, that part, if on the edge, may be pressed against a fixed object, or, if at any part of the surface, one of the fingers of the hand may be pressed gently upon that part. The plate being in a horizontal position it must be covered with a layer of fine dust; and it may be put in a state of vibration by drawing a violin-bow across its edge: the dust will then arrange itself in figures which will vary with the form of the plate, and from the way in which the bow is applied, and that in which the plate is held. If, for example, a square plate be held at its centre, and the bow be applied near one of the angles, the dust will arrange itself in lines so as to divide the plate into four equal squares (No. 1). If the plate be held as before, and the bow be applied at the middle of one of the sides, the vibrations will be such as to make the dust lie in the directions of the two diagonals (No. 2). Again, if the plate be held at A (No. 3) and the bow be applied at B, the dust will assume the positions of three lines parallel to one another: and if the plate be held at a point nearer the edge, the lines will become curves, as in No. 4.

If a circular plate, held at its centre, be pressed against a fixed object at any point on its circumference, and the bow be applied at 45 degrees from that point, the lines will take the positions of two diameters at right angles to one another, one of them passing through the point at which the circumference touches the object. A greater number of radiating lines than four will be produced if the bow be drawn more rapidly and with less pressure against the edge of the plate than in the former case. If the centre of the circular plate be free, various curve lines will be assumed by the dust, according to the position of the point which is held; and one of them is represented in No. 5. The figures represented in Nos. 6, 7, and 8, are selected from the great number which Chladni has obtained with glass plates of a circular, a polygonal, and a triangular form.

M. Felix Savart has observed, that if a rectangular plate of glass about 27 inches long, 1 inch broad, and 4 inch thick, be held horizontally between a finger and thumb at the middle of its opposite edges, and be put in a state of longi-

tudinal vibration, either by rubbing its under side, near one of the ends, with a wet cloth, or by striking it gently at one end, the dust on the upper surface will arrange itself in lines perpendicular to the length of the rod. It is remarkable, that when the plate is thus held, the vibrations being held as before, and vibrations be produced in like manner, the places of the nodal lines will be opposite to the middles of the intervals between the lines observed in the other position of the plate—a circumstance which proves that the motions of the particles in one half of the thickness of the lamina of glass are directly contrary to those in the other half. A like effect has been observed when cylindrical rods have been made to vibrate longitudinally; the line of nodes then assuming a spiral form about the cylinder, and the curves consisting of portions which run alternately in contrary directions: the points of greatest and least inclination to the axis of the cylinder are at the same distance from each other with respect to a line drawn on the surface parallel to the axis, and the effect is such as would arise if the cylinder were divided longitudinally into four quadrantal portions, having opposite qualities. The places of the nodes on that part of the rod which was uppermost were found, the rod being held in a horizontal position, by annular pieces of paper loosely encircling it.

In 1822, M. Savart read to the Académie des Sciences at Paris, an account of some curious experiments in which acoustic figures were produced in consequence of vibrations communicated through the air to elastic membranes. (Brewster's Edinburgh New Journal of Science.) A sheet of thin paper was slightly stretched over a glass vessel four or five inches in diameter, and on it was strewed light dust. A thin circular plate of glass, in a state of vibration, was then brought into contact with the paper, and the vibrations were communicated to the latter, and, the paper being of uniform thickness and well stretched, the dust assumed figures which were perfectly regular. M. Savart, having rendered the glass plate immovable at opposite points by confining it by drawing a violin-bow across its circumference. In these circumstances, on presenting the plate to the stretched paper, the following appearances were observed. The nodal figures on square paper were analogous to those formed on a square plate of glass or metal, and on circular plates their general character was circular. The circular lines were sometimes cut by diametrical lines which formed nodal points, or stars, and the number of these increased with the acuteness of the sound produced by the bow. When the plate of glass was parallel to the paper, the nodal lines were similar on both, as when two plates were connected with each other, by a rod at some distance, one fifth of the circumference of the glass plate was held vertically, the nodal lines on the paper became parallel to one another; and the figures on the paper changed as the glass plate was made to decline from the vertical position.

NODIER, CHARLES, was born at Besançon, in France, on the 29th of April, 1780. Under the care of his father, a man of stern principles and of a cultivated mind, he acquired in early life a considerable disposition for the acquirement of knowledge. At the age of twelve he entered on a course of classical study, which was, however, soon interrupted by the events of the Revolution, the principles of which his father, at that time mayor of Besançon, was solely espoused. During the Reign of Terror young Nodier employed himself in writing poetry and composing tragedies on classical subjects. These early compositions he was accustomed to read to an aged friend, who judiciously advised him to devote himself to more serious pursuits. The beneficial consequence of his advice became manifest, when five years afterwards he published a work of considerable research and great critical acumen, entitled "Le Dictionnaire des Oceanes," a monograph of French verse, in which the dictionary of words which derive their signification directly from the action which they represent (soupir, 'a name,' and soupir, to make'), as the verb 'to hiss' in our language, and 'suffler' in French. At the request of the Bibliothèque de France, it was used as a class-book throughout France, and a copy of it, by order of government, was placed in the library of every Lyceum or public school. The preface of this remarkable work on phonetic language is a great classic, and is not inferior in style to any of his later productions. During the same period of the Reign of Terror he formed an
acquaintance which terminated in the most intimate friendship with Mme. de Chateauroux, a Royalist officer, who was compelled to seek for safety in a retired country-life; through him, Nodier continued his research in the study of natural history, to which he afterwards devoted a considerable portion of his time; it was especially to the minute examination of insects and flowers that he attached himself, and his taste for it is strongly reflected in his ‘Flora de Paris’ (1817). He published in 1798 the result of his studies in a dissertation on the organs of hearing in insects, and in 1801 in a small work entitled ‘Bibliothèque Entomologique.’ In 1796 Nodier had gone to Paris to attend the meetings of the natural philosophers; he had been introduced into the best literary societies of that time. Two years afterwards he retired to his native town; but the novelty of a province and the monotony of a provincial life, he sought for novelty in the society of the political prisoners and suspected Royalists, who at that time abounded at Beaunoy. His imprudence, however, became the fortunate means of bringing his talents more prominently into notice. The convention was keeping him under the suspicion of the government, and his room was one night forced open and searched by the police agents, and his papers placed in the hands of the prefect, Jean Debray, one of the deputies of the French Republic, who was imprisoned at Rastadt by the Austrians. While searching among his papers for some traces of a political plot, Debray met with the manuscript of the ‘Oeuvres des Comédiens,’ a surprise to discover the deep research and learned disquisitions contained in a work of a young man whose habits were apparently so frivolous. With just discernment he perceived to what importance this work might be applied, and that a mind of this brilliant imagination and so persevering in study. Under his influence the work was published, with the success already mentioned.

At the Revolution which placed Napoleon on the throne, Nodier, who during the most turbulent periods of the Republic had expressed opinions favourable to the Royalists, became under Napoleon a sure Republican. Indeed, in the strict scotetion of the time, he had no political opinions. To this disposition his mind always prompted him to oppose the prevalent tendencies of the age. Thus, under the Republic, which discontenunted religion, Nodier professed openly the most religious sentiments; under the Consulate, he was at one time a Girondist, at another a Vendéan; under the Empire, he was a discontenunted Liberal; under the Restoration, he was the husband of the political party which had brought to the scaffold the brother of the reigning king. The following remark made to a young friend, who has lately published a most interesting relation of his life, is the best index of his disposition: ‘My child,’ he one day said to him, ‘of whose name I no more speak, under the suspected republican, and several men had already been arrested; when Nodier acknowledged the poem as his own. An imprisonment of some months was the result, at the expiration of which he was sent back to his native town, and placed under the inspection of the police. These measures of the government, as they were the means of excluding him from society, enabled him to devote more time to literature, and he especially attached himself to a critical study of his own language. It was during this period that he appeared his ‘Examen critique des Dictionnaires de la Langue Française;’ a work replete with the most learned and instructive remarks. To this period also is to be assigned his ‘Esquisse du Dictionnaire,’ which he composed while wandering over the country to avoid the watchful persecution of the government agents. After some years spent in this manner of life, he retired to Dôle, where he gave public lectures on French literature, which met with success unprecedented in a small country-town. It was there that he first became acquainted with Madeleine Desirée Charvès, a lady of great accomplishments and personal attractions, whom he afterwards married.

Nodier spent the first years of his married life at Quintigny, near the Jura; it was amongst the picturesque woods and meadows which adorn the neighbourhood of that town that most of the poems which have added so much to his celebrity were composed. The necessity of providing for the subsistence of his family obliged him to abandon the charms of a country life in order to settle in Paris. Previous to leaving Dôle he had studied the natural history of that town, which was attached the sum of 1000 fr., about 40l. a year, but the corporation, with a singular want of discernment, had refused it to him. In Paris he continued his literary labours near the end of the year 1810, he became a regular contributor to the ‘Journal des Débats.’ A short interruption to his residence at Paris was caused by the acceptance of the office of librarian at Laysback in Hylès, with the salary of 1800 fr., half of which he paid to an old man who had been his predecessor. The restoration of the Bourbons produced little change in the fortunes of Nodier; he continued attached to the ‘Journal des Débats,’ which paper he afterwards made the direction of the ‘Quotidienne.’ This period of Nodier’s life was rich in literary labour; each successive year he produced a work, which, taken by itself, was sufficient to confer celebrity on the author. In 1818 appeared his ‘Jean-Siflet,’ in which he displays an intimate knowledge of German literature; in 1819 ‘Théâtre Hubert,’ a short romance remarkable for the unaffected beauty of its style and the simple development of its plot; in 1820 ‘Adèle,’ another instance of the German; in 1821 ‘Smarra,’ derived from the writings of Apuleius, and ‘Trilby’ in 1822.

Nodier exposed shortly after this nomination to the important situation of librarian to the Arsenal at Paris. Nodier’s rooms at the Arsenal soon became the resort of the most distinguished literary men of the capital, who were attracted neither by the novelty of the office of the librarian, and by the charms of his brilliant and learned conversation. Among the most constant of his visitors were Victor Hugo, Lamartine, Alexandre Dumas, and Ste. Beuve. It is not the least surprising fact connected with the life of this remarkable writer, that amongst his incessant occupations of his situation, and the time which he devoted to the society of his friends, he should have produced so many works, all of which bear the stamp of originality, and are before impossible even to enumerate all his productions. He was a contributor to the ‘Bibliographie Universelle’ and other publications, and the originator of the ‘Grand Dictionnaire Historique,’ while almost daily publishing various works of a more popular character, such as his ‘Souvenirs de la Jeunesse,’ ‘Jesu de las Serres,’ ‘Les Fantaisies du Docteur Néphobus,’ ‘Dernier Banquet des Girondins,’ and ‘Franciscus Columna,’ his last and perhaps most remarkable novel. In 1834 the French Academy met him to the tardy justice of electing him a member of their body in the place of Mme. Layat.

At length, under the effects of constant application, Nodier’s health began todecline, and he died, as the witness, the event of May 27, 1845, was the last in which he was permitted to enjoy the society of his literary friends. Three days after he was taken with a serious illness, more lingering than painful, and expired on the morning of May 29th.

Nodier’s character is described by those who enjoyed the privilege of his acquaintance as peculiarly amiable and unaffected. With more than an ordinary disposition to raillery and sarcasm, he never tempred the salutary consideration to those against whom they were directed. The father of a family, who maintained by the most incessant literary labour, he had none of that irritability of temper too often the accompaniment of genius. When he was placed under the necessity of administering reproof, it was disarmed of offence by the simple modesty of his manner: to an acquaintance who had brought him a work for his perusal, in which he had made a later edition in his book, he remarked: ‘My friend, what you have given me to read cannot be very good, for, at first sight, I mistook it for my own.’

His peculiar characteristic as a littérateur is that he developed the energy of his mind no special object to which, but to write the almost every subject, and that in a way that leads one to suppose that, had he been attached to it, he might have attained the highest eminence. As a poet his merit consists in the purity of his style and diction of his thought, and his adherence to his best classical models. In one respect he deserves especial praise, the substance and moral of his works, and their complete purity as his style.
The species of Nolana are only valuable as ornamental plants; they are showy when in blossom, and are much liked by some of the trailing species of Convolvulus. The seeds should be sown as early as possible, and covered with a thin layer of soil. When the plants are of sufficient size or about the middle of May, they should be finally transplanted to the open ground, where they will flower and ripen seed; or the seeds may be sown at once in the open ground and transplanted to the garden later on. (Doe's Gardener's Dictionary; Barnett's Outlines of Botany.)

NOLLET, JEAN ANTOINE, a distinguished French philosopher, was born at Paimpô, in the Noyonnais, in 1700. It being the intention of his father, who held a farm in that part of France, that he should embrace the ecclesiastical profession, he was sent to the college of Beauvais, in order that he might prepare for the study of theology; but his taste inclining him to cultivate the physical sciences the intention was abandoned, and he was never otherwise connected with the church than by holding deacon's orders with the title of Abbé. On leaving the college he went to Paris, where he attended a course of lectures on natural philosophy, the subjects of which he studied with great diligence, repeating in his humble dwelling the experiments which he had seen performed in public. He passed many of his leisure hours in the practice of enamelling; and he is said, at one time, to have superintended the education of a son of M. Talbot, who held the post of recordman.

The Abbé Nollet supplied himself particularly, in conjunction with M. Dufay, to the subject of electricity; and he soon became distinguished by the number as well as the ingenuity of his experiments with relation to that science, performing them with great success and exactness. By his own means he contrived to make use of his valuable apparatus. He was the first who observed that pointed bodies, when electrified, gave out streams of light, but did not exhibit in other respects the phenomena of electricity, and that the smoke produced by the blunt bodies; and he found that the smoke of burnt linen and wood, and the vapour of water, were better conductors of electricity than the smoke of gun-cotton, trompette, or sulphur. He ascertained that an excited body lost none of its electricity by being placed in the focus of a concave mirror when the sun's light was concentrated in that point; that glass and other non-conductors were extremely strongly excited in the air; and that oil of turpentine on a woman's cloth was capable of producing the electric fluid in abundance; he observed also the diffusion of the electric light in vacuo. He distinguished the rays, and thus augmented the natural evaporation of fluids, and that the effect is the greatest when the fluids are contained in non-electric vessels.

In repeating the experiments of M. Boze on the effects of electricity on the scalding of fluids through tubes of iron, Nollet found that no acceleration took place when the bore of the tube exceeded ¼ inch in diameter; he ascertained however that if the bore was very small the electrified fluid did not pass through it. The absence of this resistance of his apparatus, Nollet, in 1752, performed a brilliant appearance when the experiment was performed in the dark. He electrified, during several days, the mould in a garden pot, in which seeds had been sown, and which was provided with a small window of his window. As soon as it appeared to him that the plants grew faster and produced shoots earlier than the plants obtained from the like seed in a pot containing the same kind of mould, which was not electrified. Nollet electrified in the like manner camomile, violets, sparrow, &c.; and he imagined that the animals were lighter than those of the same kind which were not so treated; from thence he concluded that electricity increases the insensible perspiration of animals. A communication of this experiment will be found in the Philosophical Transactions for 1748; but it ought to be observed that experiments relating to the effects of electricity on plants and animals have, since been frequently repeated without confirming the conclusions of the French philosopher; and it may be added, that the attempts which have recently been made to promote the growth of vegetation by an apparatus for conveying to the ground the electric fluid in the atmosphere, have been equally fruitless.

In 1734 the Abbé Nollet, accompanied by his friend M. Dufay, made a visit to England, when he was elected a Fellow of the Royal Society of London: he went from hence to Holland for the purpose of conversing with the philosophers of that country; and, on his return to Paris, he delivered a course of lectures on physics, which was well attended. In 1759 he was elected a member of the Académie des Sciences; and, during the same year, he went to Turin, where he repeated his electrical experiments in presence of the Duke of Savoy. In 1742 he went by invitation to Bordeaux, where he delivered a course of lectures; and, in 1749, by invitation of the academician of Paris, in the presence of the dauphin of France, the son of Louis XV.

Nollet made many experiments to ascertain, at various depths under water, the intensity of sounds excited in the air; and he perceived that the striking of the string of the harp, or the blowing of a hunter's horn were heard distinctly, but very faintly, at two feet below the surface. He was not fortunate however in his hypothesis concerning the nature of the electric fluid; he imagined that this fluid has two motions, viz., an afflux to the electric body and an efflux from it, and he supposed that, in consequence of the former, all light bodies are attracted or carried towards the electric; while, in consequence of the latter, they are repelled. He was also considered that all bodies have two different kinds of pores, one kind for receiving and the other for emitting the electric fluid. This hypothesis has never been admitted by philosophers.

In 1747 Signor Pivati, of Venice, published a pamphlet in which it was stated, that a man who had suffered from a pain in his side had by him been cured on being electrified with a machine in the glass cylinder of which was contained some balsam of Peru; and that two persons of great age had been cured of the gout by the like means: the benefit was supposed to have arisen from the effluvium of the balsam, which was stated to be so great that the bed and even the whole apartment of one of the patients who had received it was strongly perfumed with it. Professor Winkler of Leipzig also stated, about the same time, that he had performed similar experiments on persons affected with the gout, and that they were much relieved. It was considered that all bodies have two different kinds of pores, one kind for receiving and the other for emitting the electric fluid. This hypothesis has never been admitted by philosophers.

In 1756 the king of France endowed a chair of experimental philosophy at the college of Navarre, and he appointed the Abbé Nollet to superintend it: the zeal and ability with which the latter fulfilled the duties of his post gave full satisfaction to the king, who conferred on him the title of Master of Philosophy and Natural History to the Royal Family. Nollet was subsequently appointed Professor of Experimental Philosophy to the School for Artillery, which then existed at La Fère, and he finally removed to Paris.

He died April 24, 1779, in the Louvre, where the king had assigned to him a suite of apartments: the amiable disposition of his character was equal to his talents; and it is said that he was devoted nearly as much to the interests of his clients as to those of his parents while they lived. Besides being a Fellow of the Royal Society of London and a Member of the Académie des Sciences at Paris, he was a Member of the Institute of Bologna and of the American Philosophical Society.

The Abbé Nollet published at Paris, in 1743 and the succeeding years, a work entitled 4 Leçons de Physique Expérimen-
mentale,' in 6 vols. 12mo; this is considered as the most magnificent work of that subject which was at that time appearing, and it was the first in which the discoveries of Newton respecting the phenomena of light were stated in a popular form. His second work is entitled, 'Recherches sur les Couleurs dans les Phénomènes Éléctriques,' in 12mo of 1748; and the third, 'Essai sur l'Electricité des Corps,' 12mo, 1750. He also published, in 1758, his 'Recueil de Lettres sur l'Electricité,' in 3 vols. 12mo; and a work by him enti- tled 'Discours sur des Expériences,' was published in 1770, also in 3 vols. 12mo; this work contains the elementary prin- ciples and the practice of the mechanical arts.

(Épigraphie Universelle; Philosophical Transactions for 1748.)

NONATELLIA, a genus of plants belonging to the natural order Rubiaceae, the tribe Gustarteeae, the subtribe Moritandee. It has a calyx with an ovate tube, and a 5-toothed permanent limb; a tubular funnel-shaped corolla, with the tube as if it were gibbous, and a 5-lobed limb; the stamens five, almost inclosed; the stigma (2?) obtuse; the fruit a globose drupe, farrowed, containing 5 coriaceous 1-seeded pyrums; the albumen horny. The species are shrubs or small trees with glabrous downy-ovate-oblong leaves, and the stipules combined together more or less or free. The flowers are white and arranged in a paniculate-formed or corym- bous paniculato.

N. officinalis, A. H. Bush, has ovate, acute, glabrous leaves, the stipules combined into a 4-toothed sheath, the paniculate corymbose; the involucrum small, 3-leaved under each flower; the flower stalk is native of Guiana. It occurs in the forest, and similar places. All the parts of this plant, when bruised or dried, give out a slight aromatic odour. The creoles in Guiana call this plant Axier àusage, and it is said to have a powerful influence in subduing attacks of asthma.

There are several other species of Nonateilla, all natives of America, but some are used in the arts or as medicines.

(Loeb's Flora Medica; Barnett, Outlines of Botany.)

NORD, département DU. In our notice of this department of France, [Nord, P. C. vol. xvi. p. 258, &c.] references were given to articles CAMEM, CAMBEL, and GRAVELINES, from which in their places, references had been given to the article NORD. We here supply a brief notice of those two towns.

Cassel is situated on an isolated eminence, the summit of which, Mont Cassel, close to the town, rises to the elevation of from 300 to 350 feet, in the midst of a level country; and commands a prospect of great extent, comprehending more than thirty towns, and extending to the sea. Two streams, (one of them the little river Poeoe,) which flow into the Yser, rise near the town and furnish the inhabitants with a constant supply of water. The town, which was antiently fortified, has two gates, with large and strong gate-pierces, which have lately laid out. The population of the commune by the census of 1831 was 4234; by that of 1836, 4495; about three-fifths in the town, the rest in the neighbourhood. Some lace, stockings, hats, and coarse linen, are manufactured. There are oil-mills, and a considerable trade in cattle is carried on. Cassel has one yearly fair of seven days. The town has some historical interest. It is thought to have been one of the strongholds of the Morins, and was known in the Roman period by the name of Castellum Morinarum, whence the modern name Cassel. In the middle ages it was the scene of two severe conflicts. In a.d. 1071, Philip I, King of France, was defeated at Cassel by Robert Le Frison, who had usurped the county of Flanders from his nephew Arnulph, whom Philip supported, and who was killed in the battle. In a.d. 1298, Philip VI. de Valois, King of France, vowed a war against the Flemish insurgents who had surprised him in his camp. In later times a.d. 1677, William, Prince of Orange, after- wards William III. of England, was defeated here by the French under Lebrun. The town bears its name in the armistice of Hasembrouck, 148 miles from Paris by Amiens, Douai, Lille, Aire, and Hazemerbrouck.

Gravelines is near the coast between Calais and Dunkerque, in the department of Dunkerque, 148 miles of Dunkerque, 20 miles N. of Calais, and 170 N. of Paris by Beauvais, Abbe- ville, Boulogne, and Calais. It is a small town, but strongly fortified with a good citadel, but has very little trade. The Aa, a river that is the town for fishing is carried on, and small vessels are built. The town is laid out with tolerable regularity with wide streets. There are a church, a nunnery, a military hospital and ser vice. The population in 1826 was estimated at 10,000. The number of population in 1831, was 13,418; by that of 1836, 16,462. It is the chief place of the canton of Gravelines. The town has some historical interest from the defeat of the French in a.d. 1658 under the command of Marelle, and of Caumont, in the battle of Gravelines, assisted by some English ships that were off the coast.

NORFOLK ISLAND PINE. [Aburcaaria, P. C.]

NORMANDY, CUSTOMARY LAW OF. Previous to the Norman invasion the several districts of France were divided [Franchise, P. C.] were chiefly governed by a system of laws which, originally arising from the local usages and customs of the people, became, after time embalmed in a code which, after it had received various modifi- cations, obtained the sanction of the sovereign, and became the written and established law of the province. These codes were styled customs, coutumes, and have been largely and learnedly commented upon by various jurists of the period; their commentators were often received as law; thus we have the customs of Burgundy, Brittany, &c., commented upon by Bouvier, D'Argentiére, &c. The customary of Normandy, if not the most ancient, ranks certainly among the most perfect of the French provincial customs. According to it laws, customs, and usages, were regulations of a very different order and authority: the laws were enacted by the sovereign power, and only reduced to writing by the sovereign's grace; the customs and usages denominated the parliament of Rouen; its customs or- iginated with the people, and in time were compiled and reduced to writing by the supreme authority. Hence the dif- ference between 'loi,' 'usage,' 'coutumier,' and 'usages,' as understood in the ancient provinces of France. By 'loi' or law was understood the royal ordinances and Roman law; by 'coutumes' or customs those regulations which had been reduced to writing and received the sanction of the sovereign; by 'usage' or usages, such regulations as had not been reduced to writing. Normandy, as an independent state, and after its annexation to the crown of France under Philip Augustus [Normandy, P. C.], may be said to have had three distinct codes: 'la grand coutumier' or ancient customary, 'la charte aux Normands,' or Norman charter, and the modern customary. The ancient and modern custom related more particularly to property, &c., 'la charte aux Normands' to the political and civil rights of the subject. The Norman charter was granted by Louis X., and its principal object was to restrain the kings of France from imposing too heavy burdens on their Norman subjects. This charter was confirmed six times from its pro- mulgation to the reformation of the customary by Henry III., which fact affords a fair presumption that it had been often vio- lated. The laws of Normandy, as laid down in writing by a private hand in the reign of Louis IX., about the year 1229, which corresponds with 14 Henry III. of Eng- land. Being subjected to examination under Charles IX., many of the laws were sanctioned, and confirmed in 1641, by the Cancellier L'Hospital, and the modern reform dates from 1855 under Henry III. This custom was known throughout France by the appellation of 'la sage coutume.' The number of provincial customs of France before the Revolution were reckoned at eighty, and its local usages at nearly three hundred. In Normandy there were no less than twenty-two different modes of devising patrimonial estates, which corre- sponded to the number of vicomtes or districts of which the province was composed.

The oath of a Norman duke so late as the thirteenth cen- tury differed very little from that of a king of France: he swore to the discharge of his feudal duties, to the preservation of the unity of the kingdom, and to the obedience of the orders of the community by the impartial administration of justice, and more particularly to govern according to the Nor- man charter.

'1. A. a. a. Contumier' is divided into 125 chapters, nearly two-thirds of which are devoted to regulate the duties of the judicial officers, the proceedings in the different courts, and the respective rights and obligations of the kings of France, the duke of Normandy, the prince of Conis, the bishop of Bayeux, the duchy of Normandy, and the subject. As the power of the kings of France was very inferior to that of the dukes of Normandy, and even to that of the counts and great territorial barons, who in those days monopolised the land, and governed with it like kings, the rules of wills and inheritance, which occupy so large a portion of mod- ern law and of the reformed Norman law in the sixteenth
...the first time, from a manuscript lent him by the Marquis de Paulny, a poetical version of the customary of Normandy. Several manuscripts of this poem then existed; in one of them there was the following prologue, which, if authentic, determines its date and author:—

"Mil deux en ses quatre vols (1680)".

"A la mer de la Christ vint
Et retraite sommeign de l'imagi
Pour rendre nous, comme ses blancs,
Et par ses beaux goûts s'amuse.
O! Adam ne tailli plus,
Quand tu n'as réçu que faire.
Moi Richard D'our nel n'est
En mine qui puet pas.
"Pour le ver, le pré des fables."

There appear however at the end of the MS. of the Marquis de Paulny, which did not contain the above prologue, the following lines:

"Qud mon nom vouloit apprêter
Mes vigiles et pour vos veux
Sens le jacquier atout.
Cil y met C. A, U, P, H."

This interesting relic of ancient poetry is of considerable length, and is divided into 147 chapters; the language and details afford internal evidence of its having been composed in the thirteenth century.

The following definition of "coutumes" may be taken as a specimen of the style of 16th century literature: 

"Coutumés sont cest vieux usages
Approvés par les Princes ses
Dans sa patrie et sa mère
A s'en aviser quoy que doux prendre;
Et pour leur usage
Des douze et douze introductions,
Et des succédues
Les droits sans nul sort se doivent;
Rien de doux ni de courtois
Les droits sans retour ni appelants;
Et des coutumes, non les gens
Profes que directeurs, actifs communs

CHAP. XV.

The following is the best edition of writers on the subject of the Coutumier of Normandy:—Décisions sur chaque article de la Coutumiere de Normandie, et observations sur les usages locaux de la même Coutumie, par Pierre de Merville, Paris, 1783, in fol.; Bérault, Josias, an advocate of the parliament of Rouen, died 1820, Commentaire sur la Coutumière de Normandie, Rouen, 1804, in fol.; Basnage, Henri, born 1615, died 1695, Commentaire sur la Coutumière de Normandie, Rouen, 1678-1681; Godefroy, Jacques, Coutume du Peuple et Duché de Normandie avec les Commentaires de Bérault, Godefroy et d'Avoiron, Rouen, 1804, 2 vol., fol.; Flaut, Jean Baptiste, born 1711, died 1783, Explication de la Jurisprudence et de la Coutumière de Normandie, 2 vol., fol.; Péneille, Coutume de Normandie avec les observations de Ropnel, Rouen, 1759, 4 to.; Houard, David, born 1726, died 1808, Traité sur les Coutumes Anglo-Normandes, Rouen, 1777, 4 vol.

Hale, in his 'History of the Common Law of England' (chap. vi.), maintains that the 'Coutumier of Normandy' was written long after Glanville's tract, which was written in Henry the Second's time, and that the Norman collection was made after the time of Henry II. 

The term 'Coutumier' appears to have been made after the act of settlement of Normandy in the crown of France, for therein is specified the institution of Philip king of France, for appointing the coronation of king Richard I. for the limitation of actions, which was after the said Philip's full possession of Normandy.

Hale's opinion is that 'this similarity of the laws of England and Normandy was not by conformation of the laws of England to those of Normandy, but by conformation of the laws of Normandy to England.'

NORONHA, FERNANDO DE, is a small group of islands, belonging to Brazil, and situated in the Atlantic Ocean. The fort Concepcion on the principal island is situated 5° 50' N., lat. and 32° 13' long. The island is about ten miles long and about three across, in the widest part. The surface is mountainous, and on it is a peak which resembles a steap or tower, which is two or three thousand feet high. The soil is stony, and there are only a few small spots susceptible of cultivation. There is no harbour, and the surf runs high over the rocks, and makes it difficult to get to land. It has good water, which however is difficult to get on board the vessels, which visit this island for a supply, on account of the surf. To the north, and separated from it by..."
a narrow channel, is the Island dos Rattes (of the rats), which is three miles long, less stony and more wooded. These islands are used by the Brazil government as a place of sepulchre for the British soldiery, and their numbers amount to about eighty hundred, and the garrison consists of two hundred black soldiers. They cultivate a small quantity of mandio, a few fruits, and a little corn, and keep some hogs, that live well in this wild state, the descendants of those which have fled from the houses, are numerous. No boats are kept on the island, and no intercourse is held with shipping, without permission and the strictest in- 

(Henderson's History of the Brasil; Narrative of the Surveying Voyages of the Adventure and Beagle.)

The Morall Philosophie of Doni, drawn out of the ancient writers; a work first compiled in the Indian Tongue, and afterwards reduced into divers other Languages; and now lastly into the Latin. In 1681, 1689, 1691, 1693, 4to.

The book, besides the Lives of Plutarch, contains 'The Lives of Epaminondas, of Philip of Macedon, of Dionysus the Etruscus, of Thales of Ephesus, of Aristarchus of Samos, extracted out of good Authors; also the Lives of Nine excellent Chieftains of the Etruscans, taken out of Latin from Esyllus Probus, by S. G. S., by whom also are added the Lives of Plutarch and of Seneca, given in his works, and earnestly recommended for Study. The work is now translated into English by Sir Thomas North, Knight.'

This part of his book is also dedicated by North to Queen Elizabeth, to whom he seems to have been indebted for some kind service.

In 1689 he was admitted fellow commissary of St. John's College, Cambridge. He afterwards became a member of the Middle Temple. He passed his time gravely and studiously, and appears early to have resolved not to leave any plan untried, whether by his own strength, time, and labor, or by the advice, wealth, power, and distinction of his friends. His relaxation consisted of music meetings, hearing Hugh Peters preach, and occasional convivial sallies with fellow-students—very small items of dissipation, the nature of the times and the habits of the young

lvery of the Restoration considered. He was well-connected, and received some aid and supplies from his relatives in his early struggles. His practice however was for some time small, being chiefly exercised amongst the middle classes of London, and in the country, but in the course of time, much of the business destined for him fell to the lot of his father's favourites, young Francis North. He went on the Norfolk circuit, which brought him into the neighbourhood of the family and brought him the opportunity to let his character be known, and it soon seemed likely to aid him slip from his hands.

'The lord kept by his brother, Roger North, is one of the simplest developments of private life and habits during the seventeenth century which our literature possesses. We are let into all the hopes and fears of the young aspirant—his paucity and dishonest tricks, his gracelessness, much coarseness, his trilling politics, and his readiness to do any work that persons well intrenched in power might set before him. The book is all the more curious because its author never, even in his later years, devotes himself to political work; but watches as that patient perseverance in well doing which finally brought him what he practised them to solid honour and wealth. Standing between a Shaftesbury and a Jeffreys, North's character has a particular charm, a kind of romantic touch, something unanswerable, and perhaps the honest indignation which his character has elicited from Lord Campbell seems rather disproportionate when the nature of the times is considered. The man is particularly instructive in describing his attempts to obtain a rich wife, bestowing hearty commendation on the skill and intrepidity with which he foiled every effort to ally him to anything under the desired standard of wealth. Other qualifications apper to be of small concern. One of his negotiations is thus told:—There came to him a recommendation of a lady, who was an only daughter of an old weaver of Gray's Inns, supposed to be a good fortune in present, for her father was rich: but, after his death, to be worth nobody could tell what. His lordship got a sight of the lady, and did not dislike her: thereupon he made the old man a visit, and a proposal of himself to marry his daughter. There appeared no symptoms of a bargain; but the old gentleman asked him what estate his father intended to settle upon him for present maintenance, jiuseure, and provision for children. This was an insidious question, for it was plain from the father's manner that he was at present not a man of any establishment, and one would be to spare for him. Therefore he said to his worship only "that when he would be pleased to declare what portion he intended to give his daughter, he would write to his father and mention his offer. And so they parted, and his lordship was glad of his escape, and resolved to give that affair a final discharge, and never to come near the terrible old fellow any more. His lordship had at this time the advice of a friend, who says, 'tis a princely bounty of your blessed hand (most gracious Sovereign), comforting and supporting my poore old decayling life, of right challenging the travel of my study, the labor of my body, and the prayer of my devotions, to be wholly employed for your Highness, and alsoother devoted to your service.'

(North's Bibliotheca Britannica; Biographia Universelle, article Doni.)

North, Francis, Baron Guildford, lord keeper of the great seal of England, the immediate elder brother of the following, was born, as Lord Campbell has discovered from the inscription on his tomb-stone, on the 22d of October, 1674. He was admitted fellow-collegium of St. John's College, Cambridge. He afterwards became a member of the Middle Temple. He passed his time gravely and studiously, and appears early to have resolved not to leave any plan untried, whether by his own strength, time, and labor, or by the advice, wealth, power, and distinction of his friends. His relaxation consisted of music meetings, hearing Hugh Peters preach, and occasional convivial sallies with fellow-students—very small items of dissipation, the nature of the times and the habits of the young
flourished, being, instead of vacation in term, rather term in vacation, so large was the increase of trials by misprin out of the court, as also of motions and pleas in the court. These struggles are well known to have had great influence in the practical extension of the jurisdiction of the three courts of Westminster Hall, Middle Temple, and Inner Temple, by the late great dabbled with to lose sight of his own ultimate interest. Knowing that, from the difficulty felt by the king in obtaining payment of the large sums he had spent, the new keeper should have no salary beyond the fees of his office, and conscious that he was the only person who had at that juncture a substantial claim on the appointment, he refused to touch the seals until, "for his majesty's honour," they were accompanied by a pension of 3,000l. A year as a judge, he was almost invariably in favour of the prerogative, and seldom if ever endangered his influence at court by his independence. A bold and a still more arduous instrument of power was however gradually undermining him in his latter days in the person of Jeffrey's, whose ascendancy and presumption seem to have completely broken the spirit of the lord keeper. His military and political career shows that he had not been side-tracked with the crudities of Jeffrey's campaign; but Lord Campbell, in a comparison of dates, finds that the lord keeper's death occurred at too early a period in the history of the massacre to allow of his having been a Jacobite. He died on the 9th of September, 1685. He was, in private life, a moral man even for an ordinary age, and a miracle in the reign of Charles II. On his professional merits, Lord Campbell speaks of the bequest of his peers, and the state contained, but he was incapable of taking an enlarged and commanding view of any subject. (North's Lives of the Norths; Campbell, Lives of the Chancellor, ii. 495.)

NORTH, SIR DUDLEY, the third son of Dudley, Lord North, Baron of Kennington, was born on 16th May 1641. In childhood he was lively and active, and having strayed from his father's house, he was discovered sleeping with a woman of bad character, and with difficulty recovered. He made little progress in literary education, and his brother and biographer tells us that he had a strange bent to traffic, and while he was at school, drove a subtle trade among the boys by buying and selling. In short, it was considered that he had learning enough for a merchant, but not phlegm enough for any sedentary profession, which judgment of him was made good by the event.

Being 'boused' to a Turkish merchant upon the ordinary terms to be sent abroad, he was sent as supercargo to Archangel and Smyrna. He left an animated and curious journal of his voyage to Archangel, and his subsequent progress by Italy to Smyrna, where he resided and traded. He dedicated the work to the public and to the nation, and was the author of a book on the education of a scholar, but it is full of amusing descriptions and sagacious remarks. After a residence for some time in Smyrna, where he suffered from disease, he removed to a factory at Constantinople under King Charles II. He returned home in 1678, and in 1680 he said "that for scolding and railing it was more apt than any other language." He left some curious information about Turkish manners, particularly as to the administration of justice, with which he had some practical experience. His experience and observations are generally printed in his memoir as he wrote them; but on some occasions, when his brother professed to render them in his own language, the biographer being a practising English barrister, makes a singular jumble of the Turkish administration by putting his allusions to it into the technical phraseology of the English law.

Very few dates are given in his biography, but it is stated that Dudley was on his way home having touched at Smyrna, left that place on 28th March 1680. He wrote, as long a journal of his return journey, A Voyage from Smyrna, with an Account of Turkey, containing matters little known in Europe, left unfinished. He spent his latter years in London. Soon after his return he was chosen sheriff, and knighted by the Lord Mayor, and was admitted to the inner chamber of the Exchequer. By the interest of his brother, the lord keeper, probably as much as by his own merits, he was made a Commissioner of the Customs. Towards the end of the reign of Charles II. he was made a bailiff of Rotherhithe, and then one of the Victuallers of Rathbone Place. By the interest of the new keeper, the lord keeper, probably as much as by his own merits, he was made a Commissioner of the Customs. The life of the second of the reign of Charles II. he was made a tax collector in the City of London. In the reign of William and Mary, he was the first man in the Custom House. He died in 1692, and was buried in the church of St. James's. He was set back to his office in the Customs. He made himself somewhat unpopular in his office by suggesting a tax on sugar and tobacco. In the mean time he had been chosen member of Parliament for Banbury, and took considerable interest in politics, with, apparently, a far more independent spirit than his brother, the lord keeper. His biographer relates for him the merit of having offered resistance to the king under the excitement of the "clawing." He lost his office at the Revolution, and was subjected to a great deal of pain and hardship. His imprisonment on account of his examination by both Houses of Parliament. He died on 31st December, 1691. (North's Lives of the Norths.)

NORTH, ROGER, the sixth son of Dudley, Lord North, was born about the year 1680. He studied in the Middle Temple, and became a member of the court of Archbishop Sheldon. It is stated in Reece's Cyclopaedia that he was Attorney-General under King William III. He is mentioned in the list of Attorney-Generals in Butter's Political Index. He died in 1783. He left, in manuscript, some Memoirs of Music, which met with approbation from Dr. Burney. In 1740, a quarto volume was published called Examinen, or an Enquiry into the Credit and Veracity of a pretended complete History, showing the perverse and wicked design of it, and the many Fabuluses and Absurdities of Truth contained in it, together with some Memoirs occasionally inserted, and tending to vindicate the Honour of the late King, Charles II., and his happy Reign, from the intended Aspersions of that foolish Pen. The work against which this volume is leveled is Poussier's 'Compendium of Music,' and it is a partizan object, much insight may be had into the state of society and politics during the reign of Charles II., by a personal of the Examinen, and when measured by a higher tone of independency, it is evident that the simplicity, which this partizan object, much insight may be had into the state of society and politics during the reign of Charles II., by a personal of the Examinen, and when measured by a higher tone of independency, it is evident that the simplicity, which this

(Article by Burney, in Reece's Cyclopaedia; Collina's Paege: Works referred to.)

NORTHUMBERLAND AND INLET, is a large bay on the eastern coast of North America, running nearly parallel to Davis's Strait and entering the continent to a distance of more than 150 miles from the open sea. Its entrance lies between 64° 36' and 63° 50' N. lat., and 68° 10' W. long. It extends in a north-western direction with a width varying between 40 and 50 miles to the north of 66° N. lat., where it begins to grow narrower, and it terminates in an inlet not more than three miles wide, where the latitude is 66° 30' to 67° N. lat. Though by its geographical situation this bay appears to be placed without the general course of the icy masses, which during the summer are met with along

Digitized by Google
the coast of this part of America, the prevailing southerly and south-easterly winds, and the tides, which rise to twenty-five feet and more, bring during that season large masses of floating ice into the bay, which circumstance renders its navigation rather difficult. The country along the shores of the inlet is very rocky, and in the vicinity of the ocean mountainous. Near the western shores is Mount Hecla, whose summit rises to 2000 feet above the sea-level, being to an estimate. Farther inland the country appears to be less elevated. The shores of the bay, especially on the western side, are beset with numerous rocky islands and cliffs. It does not appear that this inlet is much visited by whales; nor are other fish abundant. But as it is pretty well peopled by Eskimaux, wild animals probably are numerous. The Esquimaux have also several stations, at which great numbers of salmon are caught. This inlet was first explored or discovered in 1641 by Captain Wareham.

(London Geographical Journal, vol. xii.)

NOSOLOGY, (from ουσα and μελες), is the term applied to the classification and arrangement of diseases. It was early found in the observation of the symptoms of disease, that many of them recur again and again, and this led to the assigning to such groups of symptoms particular names. Thus we find that the term fever was early applied to designate a certain set of symptoms, and, as any of these symptoms preponderated, the fever obtained a specific name, as putrid fever, pestilential fever, etc. But not only were symptoms had recourse to for the purpose of distinguishing peculiar forms of fever, but the causes and the locality were frequently employed; thus marsh, jail, hospital, and other fevers have been described. In this way the various were early accumulated for the formation of a system of nosology. It was, however, still comparatively modern times, that anything like a scientific system of arrangement was proposed. One of the earliest of these was that of Sauvages, who, taking the most prominent symptoms of diseases as his guide, divided them into ten great classes which he named Vitia, Feberas, Phlegmasia, Spasmi, Anhelationes, Debilitates, Dolores, Vessanum, Fluxus, and Cachexia. Under these classes were arranged various orders: thus, under the first class Vitia, he arranged the orders, Maculae, Efflorescentia, Phymata, Excrecentia, Cystides, Ectopia, Plague. The order Maculae was divided into the diseases Leucoma, Vitilego, Ephelis, GuTa rosea, Naurus, and Ecchymosa. This classification of diseases was followed by those of Linnaeus, Vogel, Sager, and Macbride, but in their arrangements they all recognized the same principle of classification as Sauvages, and made their division of diseases to depend on the greater or less prominence of particular symptoms. All these systems, were, however, supplanted by that of Cullen, which he promulgated in the second edition of his "Synopsis Nosologicum Medicinae." The following plan will give an idea of its structure:

### CLASS I.—PYREXIAE.

| 149 Caries |
It was the simplicity of this system which recommended it to goers and to numbers of numerals; for it has a great influence over other systems of pathology. At the same time it will be seen that this and the previous systems are purely artificial, and frequently bring together diseases of different kinds, on work of Boethius, particularly in those on music, and they seem to have obtained universal currency in the middle ages by means of the work of Boethius. The study of music was also led to the impression that diseases have a character as definite as the objects of natural history, and that a species in one area be as easily defined as the species of another. But it becomes evident, after a little. It is with the exception of those diseases that depend upon specific contagion, no part of the idea of a species as applied to plants or animals can be made use of to designate particular diseases.

With the knowledge of pathology and pathology, many attempts have been made to give a natural arrangement of diseases than that of Cullen. Dr. Mason Good divided diseases into the following six classes:

- **Class I.** Catarrh. Diseases of the digestive functions.
- **Class II.** Pneumatics. Diseases of the respiratory function.
- **Class III.** Haematia. Diseases of the sanguineous function.
- **Class IV.** Neuromata. Diseases of the nervous function.
- **Class V.** Genitae. Diseases of the sexual function.
- **Class VI.** Eclipsia. Diseases of the excretory function.

This system, however successful it may be regarded in its primary divisions, was too technical in its details to be very generally acceptable. The system of natural classification founded on pathological distinctions is that of Pinel, who divides diseases into fevers, inflammations, hemorrhages, neomias, and organic affections. The great object of Pinel's so-called natural classification was to give knowledge of the functions of many parts of the human body, whilst the symptoms of diseases, being very evident, led to the assumption of causes of disease and pathological states which probably do not exist.

(Cullen, *Systema Nomenclatura Medicinae*)

NOSTOC [Zoogaptes, P. C.]

NOTODANUS, a genus of fossil fishes from the lant of Dorsetshire. (Agass.)

NOTITIANUS, a genus of fossil fishes from the chalk of Kent. (Agass.)

NOY, WILIAM, a lawyer, whose professional career had a considerable influence on British History, was born about the year 1577. He was, says Fuller, for many years, the strongest champion of the subjects' liberties, until King Charles entertained him to be his attorney. He was made Attorney-General on 31st October, 1631. He had for some years been member of Parliament, first for Helston, and subsequently for St. Ives. He was a profound lawyer and juridical antiquity; but, as Clarendon says, he could not give a clearer testimony that his knowledge in the law was greater than all other men's by making that law which all other men believed not to be so. It was to his researches in the profound and subtle abstractions of common law, and to his clear, rare spirit, that the court owed the project of ship-money. Noy drew the writ for levying this illegal tax, but he did not live to see the momentous effects of his exertions, and died on 6th August, 1676. It was noted in the journals of the day, that the death of Noy deprived the King of a valuable lawyer. The judge of the King's Bench, when answering a question upon the Rights of the Crown; declaring how the King of England may support and increase his annual revenues, 1715, 8vo. He collected Reports and Cases taken at the time of Queen Elizabeth and James I. Author of the book: *The Compleat Lawyer.*

**NUCLEUS, [Scott, P. C.]**

**NUMBER, [THOMAS, P. C.]**

**OLD APPENDICALES OF.** The student of books viewing on the middle ages will occasionally meet with some designations of numbers, or rather of the ratios of numbers, which have descended, which have descended from numbers of a theological character, and they should be utterly lost sight of, for they form a dark background on which the merits of Sacrobosco, Bradwardine, Niels., II. - 3 B

*With numbers of*
NUMBRN.AS, THEORY OF. We are here to apply an omission in the article on this subject, or rather in filling up the table of the nation which were made for the previous one. Euclid's geometry, assuming only the use of his three celebrated postulates, enables him, a linear unit being given, to construct the length represented by any algebraic expression which involves only additions, subtractions, multiplications, divisions, extraction of the square roots, or combinations of all these. But a cube or fifth root is beyond the power of the system. Again, from the theory of equations it is soon made obvious that the solution of the equation $x^2 - 1 = 0$, and the division of a circle into $n$ equal parts, are one and the same problem. One solution of the preceding is $x = \cos \theta + \sqrt{-1} \sin \theta$, where $\theta$ is the nth part of four right angles. [Boor, P. C.] Euclid, in his fourth book, shows how to cut a circle into equal parts; and analysis shows that the sines and cosines of the angles so involved can be obtained by formulae which involve no roots except the square. But except into halves, thirds, fifths, or sevenths, or parts obtainable from these by one or more bisections, Euclid was not able to cut a circle into equal parts.

So the matter rested for about 2000 years, until Gauss, in his 'Disquisitiones Arithmeticae' (1801), not only pointed out how to extend Euclid's conclusions, but also in a manner how to account for them. The statement of his results, even when they are instructive to the learner, and we shall give it accordingly: referring for the demonstration to the works of Gauss or Legendre [Numbers, Theory of, P. C.], or to Murphy's 'Theory of Equations.'

The expression $a + \sqrt{b}$ and $a - \sqrt{b}$ being rational, is the solution of a quadratic equation with rational coefficients. But if $a$ and $b$ themselves have the form $c + \sqrt{d}$, in which $c$ and $d$ have the same form, and so on; then $a + \sqrt{b}$ is the solution of a quadratic equation in which the coefficients are themselves the solutions of the quadratic equations, whose coefficients are again the solutions of quadratic equations, and so on. Consequently, any equation, the root of which is capable of construction by Euclid's postulates, must be reducible to a system of quadratics; and the converse. Now if $n$ be a prime number, $n = 1$ is an even number, and therefore has factors. Let its prime factors be $2, 3, b, c$, &c., and let them several enter $p, q, r, s, &c.$ times; so that $n = 1 = 2^p \times 3^q \times b^r \times c^s$.

Gauss succeeded in showing that when $n$ is a prime number, the solution of the equation $x^n - 1 = 0$, can be made to depend upon the solution of $p$ equations of the second degree, of the $q$th degree, $r$ of the $b$th degree, and so on. Consequently, whenever $2 = 1$ is the only prime factor of $n - 1$, or when $n = 1$ is prime, or when $2^p + 1$ is a prime number, the sevenfold is reducible to the ninefold quadratic equations, and the division of the circle into $n$ equal parts can be accomplished by Euclid's geometry. And further, it is easily demonstrated that $2^p + 1$ can never be a prime number, except when $p$ itself is a power of 2 (2 included) though $2^n + 1$ is not always prime. Nor has it been shown that other divisions are impossible: Gauss's theorem merely points out cases where the thing can be done, without pronouncing the exclusion of others. Gauss, indeed, does assert that he can demonstrate all other cases to be impossible to be constructed by geometry, that is, reducible to quadratic equations: and the thing is highly probable. If we now construct the series $2^2, 2^4, 2^8, 2^{16}$, &c., among which all our chances lie, we have, 5, 17, 257, 55287, 4294967297, &c. The first five are prime numbers: Euclid has disposed of the two first divisions; Gauss has added that a circle can be concentrically divided into 17, 257, and 55287 equal parts. But 4294967297 is not a prime number, being divisible by 641. Euclid's mode of obtaining the division into 18 parts can also be extended.

From $a$ and $b$ we get $\frac{a + b}{2}$ by their difference, as in Euclid; and thence $a$. From $a$ and $b$ we get $\frac{a - b}{2}$, and thence $b$. From $a$ and $b$ we get $\frac{a + b}{2}$, and thence $b$. Consequently the circle is divisible geometrically into the following numbers of equal parts.

$$\frac{a + b}{2} \quad \frac{a - b}{2} \quad \frac{a + b}{2} \quad \frac{a - b}{2}$$

NUTRITIA. [COPYS, P. C.] NUTRITIA is a genus of Trilobites, from the Silurian strata of Tyrone. (Fortlock.) It occurs also in England and Wales.

NYCTERIBIA, a genus of parasitic insects of the order Diptera. They are closely allied to the horse-flies (Hippoboscis) which have neither wings nor balancers. Their intermediate legs are connected at the base by a pair of comb-like organs composed to represent wings. They live on the bodies of bats.

NYPHMAEA. [WATER-LILY, P. C.]
OATMEAL. [Avey, P. C. S.]

OBLIQUE ARCH. [Skeew Bridge, P. C.]

OBEQUESUS, JULIUS, the author of a small work in Latin which is entitled 'De Prodigis.' Nothing is known about the author. Scaliger concludes that Obequensis lived before Hieronymus, because Hieronymus in a particular passage appears to have copied a fact from Obequensis. This passage of Hieronymus was written in the time of Valens, who died a.d. 379. The work of Obequensis is a record of wonderful things that happened during the period from the foundation of Rome to the time of Augustus. The first part of the work is lost, but it has been supplied by Lycoctonos, whose supplement commences with the time of Romulus and extends to the year of the City 568, when the extant work of Obequensis begins. There are various gaps after 568, which Lycoctonos has also supplied. The method of the author is to enumerate the wonderful occurrences under any given year, and then to state what happened thereon. The following is an example: (No. XCI.)—'It rained milk on the Grecostaisia. At Croton a flock of sheep with a dog and three shepherds were killed by lightning. At Saturn a calves, with two heads was born. There was an uproar in the city owing to Grecusius proposing his laws.' Obequenses chiefly followed Livy, for he uses pretty nearly Livy's words, as appears from a comparison of Obequensis with those parts of Livy which are extant. His work also terminates with an event in the life of Augustus, and from the description of his life, and the history of Livy terminates with the death of Drusus.

Lycoctonos in his preface argues that the attention which the Romans paid to wonderful occurrences and signs proved their religious feeling; their religion is shown by their worship of false deities; and he adds that if they had been acquainted with the true religion, they would have surpassed in religious zeal their posterity, who are Christians rather than heathens, and that the events of the times foretold by Jesus Christ (Luke xxi.) as to happen when the end of the world was approaching. Among the signs then recently witnessed the author mentions three or four eclipses happening in a year, stars with hair (cometes), burning meteors, and earthquakes and convulsions of the earth in Italy, all which made no impression on the people of that day, to such a height of impurity and wickedness were men come. The consequences of all this were pernicious errors, horrible blindness, and persevering blasphemy; and the divine vengeance showed itself in civil wars, strange diseases, and famines. The author thought that an edition of Obequensis would be of some use, and that the portrait is published in the work of Eckhout and Bungea, 

ODOVAERE, JOSEPHUS DIONISIUS, the most celebrated historical painter of the Flemish school of recent times, was born at Bruges, October 3, 1778. He was brought up in the college of the Augustines of that city, and was destined by his parents for mercantile pursuits, though he had always displayed a decided ability for the graphic art. In 1794, in consequence of the French invasion of Belgium, Odoevaere was removed by his parents, and accompanied them into Holland, where he remained fourteen months. They returned to Bruges, and as Odoevaere had a continued dislike to a mercantile pursuit, he was placed in the Academy of Bruges, in which he obtained the first prize for drawing in 1796. He went, towards the close of the following year, to Paris, and studied in the school of his fellow-townsmen Suvee until he was appointed director of the French Academy at Rome, in which he obtained the first prize for drawing in 1804. He obtained the grand prize of the French Academy of Painting, for a picture of the death of Phocion, and had the honour of being presented to the emperor. He returned in the same year to Bruges, and in 1805 he went as a pensioner of the French government to Rome, but he remained there together eight years, and experienced the regulation of the French government, he sent, after his residence of five years in Rome, an historical picture to the French Academy; the subject was the Coronation of Charlemagne; and it was received with approbation. He was then appointed a commission in Rome to paint two large frescoes for the palace of Monte Cavallo, but political events which followed prevented the execution of these works. He left Rome at the close of 1812, and returned to Paris, and obtained the gold medal for a picture in the exhibition there. He returned finally to Bruges, where he executed several public and private commissions. In 1814 he established himself in Brussels, where he painted his pictures of the Peace of Utrecht, and the Battle of Waterloo at the moment the Prince of Orange was wounded, for the King of the Netherlands, who had created Odoevaere his own painter in the spring of 1815. The Battle of Waterloo was exhibited in 1817 and 1818 in many of the provinces of the Netherlands, together with a portrait of the Prince of Orange, which is engraved by Lignon, and a picture of Brumante introducing Raphael to Julius II. Odoevaere was the commissioner appointed on the part of the Netherlands to reclaim the pictures which had been taken by the French from Paris, in the collections of the King of Holland and Belgium. In the completion of this commission, the King created him a Chevalier of the Lion of the Netherlands, and several Flemish cities presented him with medals struck expressly in commemoration of the restoration of their respective liberties.

The Battle of Waterloo was followed, in 1820, by the Battle of Nieuwpoort, and a Narcissus, engraved by Vlamynck. In 1821 he exhibited at Brussels his Triumph of Cimabue: a work executed subsequently to a commission in his studio: the establishment of the Power of the House of Orange; the Inauguration of the King at Brussels in 1815; besides others from classical history, and many scripture-pieces for various churches in the Netherlands, in some of which are excellent altar-pieces by Odoevaere. He died at Brussels, in February, 1850, not having completed his fifty-second year. Van Eynden and Vander Willigen, in the third volume of their 'National History of Painting since the Middle of the Eighteenth Century,' published in 1820, have given December 2, 1775, as the date of Odoevaere's birth, which is corrected in the fourth volume of appendix, published in 1840, to the date given above. His portrait is published in the work of Eckhout and Bungea, "Portraits des Artistes modernes," etc., Brussels, 1829; and several of his works are engraved in the "Annales du Salon de Gand"—as the Coronation of Charlemagne; the Confession of the Duke of Saxony; and the Death of the Prince of Nieuwpoort. Some of the pictures of Odoevaere are of very large dimensions. He was a member of the Academy of St. Luke at Rome, and of several other institutes of the fine arts.

R. Van Eynden en A. Van Der Willigen, Geschiedenis der Nederlandse Schilderken, zedert de hefst der xvii. Eeuw, Amsterdam, 1842.)

ODOVNIETER (from ides, a road, and μετρον, a measure) is an instrument used for measuring the distances passed over in travelling, and is very nearly the same as that which is called a Pedometer; the latter is carried in the pocket of a person on foot or on horseback, and the former is attached to a carriage. (Pedometer: "OECUMENICAL COUNCILS. [COUNCIL OF THE CHURCH, P. C. S."

IZEDEMA, a genus of beetles belonging to the third family of heteromorph Colocerata, the Spherinae. Genothiera, a genus of plants belonging to the natural order Onagraceae or Onagraceae. It has a 4-cleft calyx, 4 petals, a filiform style, with a callos or crumiform stigma, linear capsules of 4 cells, with a long aril. C. binenis, Evening Primrose, has ovate lanceolate flat- toothed leaves, a rough hairy stem, petals longer than the stamens and about half as long as the tube of the calyx. The flowers are large, and abundant in groups at the end of a long stem. It abounds on the Lancashire coast, and covers several acres of ground near Woodbridge, Suffolk. The roots are edible.

21 3
and were formerly taken after dinner to flavour wine as olives now are; therefore the generic name was changed from Osage, the ass-fool, to Olea, the wine-feeder. This plant was
more cultivated for the sake of its tubers, which might in some measure have stood instead of the potato had they not been superseded by the introduction of the latter in this country. This is the only British species in the genus. There are 85 species enumerated for
Don, growing chiefly in North America. They are
handsome border flowers, and deserve to be cultivated, but are not valuable on account of any properties they possess. They will grow in any common garden soil. The perennial
kinds are usually propagated by seed, by dividing the plants at the root, and some of them by cuttings. The seeds of the annual and biennial kinds only require to be sown where the plants are to remain.

(Don, Gardener's Dictionary; Babington, Manual of
British Botany; Burnett, Outlines of Botany.)

OFFERINGS, OBLATIONS, AND OBSESSIONS are
not only those small customary sums paid at Easter, but also the customary payments for marriages, christenings, churchings, and burials. By 2 & 3 Ed. VI. c. 13, 'all persons which by the laws and customs ought to make or pay their offerings, shall yearly well and truly content and pay the same to the parish, vicar, proprietor, or their deputies or farmers, of the parishes where they shall dwell or abide: and that at such four-offering-days as at any time hereafter may be within the space of 5 years, shall have been accustomed for the payment of the same; and, in default thereof, to pay for the said offerings at Easter then next following.' The four offering-
days above spoken of were Christmas, Easter, Whitsuntide, and the dedication of the parish church. It is directed by the rubric, at the end of the Communion Service, that 'yearly at Easter, every parsoner shall reckon with the parish, vicar, or curate, or his or their deputy or deputies, and pay them what was due from them all ecclesiastical duties accustomably due then at that time to be paid.' Easter offerings are due of common right, as well as by custom. (Bunb. 178, 128.)

Thus, in Carthew v. Edwards, Trin. 1749, it was decreed by the Court of Chancery that the Easter offerings were due to the plaintiff of common right, after the rate of 2d. a-head for every person in the defendant's family of sixteen years of age and upwards. But by custom the sum may be more. In London 4d. a-head is usually claimed. By the Small Tithe
Act, 7 & 8 Wm. III. c. 6, offerings, oblations, and obser-
venations may be recovered before justices of the peace.

Surplus-fees are payable for every marriage, christening, or baptism, according to the custom of the parish. Mortuaries are claimed on the death of each person in a parish, according to the value of property left, but not to a greater amount than 10s. (Babington, Ecclesiastical Law.)

OGGIONE or UGGIONE, MARCO DA, a Milanese painter and distinguished scholar of Leonardo da Vinci at Milan about 1490; he was born about 1470, at
Ligorna in the Milanese. He painted in oil and fresco, and is on the whole one of the best of the
Milanese painters. His frescoes of the church della Pace at Milan, which are much praised, are now in Brera at Milan; they were removed from the wall by Barezzi. Oggione is however now chiefly known for his copy of the 'Last Supper' of Leonardo da Vinci, now in the Academy of Arts in London. This copy is painted in oil, and was executed about 1510 for the Refectory of the Certosa di Pavia; and as it was copied when the original was in a perfect state, the now almost total decay of the latter renders it very valu-
able. The opinions regarding its merits are various. Giuseppe Boffi does not wholly approve of it; but as the original has been virtually decayed since 1726, when it was first restored, all subsequent judgments of the merits of the copy with respect to the original must be received with due reservation, as they are certainly the result of individual fancies of what the original might have been, rather than of what it by actual comparison was found to be. Marco da Oggione's copy must be a better criterion of what the original was than the remains of all the critics combined; they have no right to assume a deviation from the original, when they cannot possibly demonstrate it. Oggione made two large copies, both, it is said, now in the Museum, that in oil, in the Royal Academy, and one in fresco for the Refectory of the convent of Castel-
lazzo, which was copied by the Cav. Giuseppe Boffi, though Boffi's picture was taken chiefly from a copy in the Ambra-
sian Library made by Andrea Pannini and Vespinal in

1819, when the original was already much decayed. There is an older copy at Ponte Castrice, made in 1655, and attributed to Pietro Luni. Bossi's copy was made in 1807 for Eugene Beauharnais, viceroy of Italy, to be worked in mosaic; the cartoon is now at Munich, and the mosaic was made from one copy partly from another, from studying other works of Da Vinci, and from the artist's own feeling of Da Vinci's style, is essentially a restoration or translation, and not a copy; it may have no resemblance to the original in foreshortening and composition; and to the true
lover of art can have little value, compared with the old un-
assuming copy of Oggione. The mere fact that Oggione's

1372

OIL

OIL MANUFACTURE OF. An account of the properties of the more important oils, and of the materials on which they are produced, is given in Oils, Vinegars, p. 417, and in Oils, Vinegars, p. 415, and Oils, Vinegars, p. 417; and further information may be found under the names of some of the principal oils, as Croton OIL, Linseed OIL, and Olive OIL, or in articles which treat on the materials from which oils are made, such as Elaeis, Mandia, Linseed OIL, Olive Europea, Richmon, Communist, and Guacharo Bird. Under Fisheries, also [P. C., pp. 288, 289], is given much information on the production of whale oil. We may here add a few words on the processes of the manufacture of such oils as are of the greatest commercial importance.

The manufacture of animal oils requires very little notice beyond what is given in the articles Oils and Fisheries above referred to. The blubber, or fat from which the oil is pro-
cured, is usually cut into small pieces and packed in casks soon after it is taken from the whale; it is then brought home in a half-frozen state, and is emptied into the oilummy or receiver, capable of holding several tons. From this receiver the decomposing fat is conducted, after settling for a few hours, into a copper boiler, in which the separation of the fluid from the solid is completed by the application of heat. From the boiler the oil flows through a kind of filter of brushwood, which detains the greater impurities, into coolers, from which, when quite cold, it may be drained into smaller casks. Various driers are employed for purifying whale oil and diminishing its unpleasant smell. The quantity of oil obtained is about four-fifths that

(Gran, Storia Pittorica, &c.; Gothé, Propylæum.)

OHMACHT, LANDELIN, an eminent German sculptor, born at Danzig near Rottwill in Württemberg, in 1760. He was the pupil of J. P. Melchior. His first public works were some sculptures for the Kreuzkirche at Rottwill, which still remain in the choir.

His last public work was the good boat of Lavater. In 1790 he went to Rome, where he remained two years, and after his return to Germany he was employed on several important monumental works, which were the most important to his master Rихo, in the cathedral of Lübeck; but his principal works are at Strasbourg, where he settled in 1801. His first work there was the monument of General Desaix, who was killed at Marengo, erected on the Rhine, not far from Strasbourg; Thomas, of which that to Professor Oberlin (1810) is one of his principal works; that to the historian Koch (1815) is likewise much admired. He executed an important document in the new church to Dr. Blessig; another to General Kleber, in the cathedral; and a colossal figure to Adolph von Nassau, in the cathedral of Speyer. There are also several minor works, by Ommacht—A. Hebe; the Judgment of Paris (at Nymphenburg), and others. Among his busts are several of Klopstock, with whom he was intimate. He died at Strasbourg, in 1834; his portrait is in the Vogel collection of portraits in the possession of the king of Saxony. The celebrated sculptor David, upon seeing the works of Ohmacht at Strasbourg, is reported to have said that one could not sufficiently admire them, and that Ohmacht was the Correggio of sculptors.

OIL-PAINTING. [Eyck, John Van, P. C., p. 133; Painting, P. C., p. 142; Oil-Painting, P. C., p. 145; Painting, House, P. C., p. 145; Sturze, P. C., p. 479.)

OLDS, MANUFACTURE OF. An account of the properties of the more important oils, and of the materials on which they are produced, is given in Oils, Vinegars, p. 415, and Oils, Vinegars, p. 417; and further information may be found under the names of some of the principal oils, as Croton OIL, Linseed OIL, and Olive OIL, or in articles which treat on the materials from which oils are made, such as Elaeis, Mandia, Linseed OIL, Olive Europea, Richmon, Communist, and Guacharo Bird. Under Fisheries, also [P. C., pp. 288, 289], is given much information on the production of whale oil. We may here add a few words on the processes of the manufacture of such oils as are of the greatest commercial importance.

The manufacture of animal oils requires very little notice beyond what is given in the articles Oils and Fisheries above referred to. The blubber, or fat from which the oil is procured, is usually cut into small pieces and packed in casks soon after it is taken from the whale; it is then brought home in a half-frozen state, and is emptied into the oilummy or receiver, capable of holding several tons. From this receiver the decomposing fat is conducted, after settling for a few hours, into a copper boiler, in which the separation of the fluid from the solid is completed by the application of heat. From the boiler the oil flows through a kind of filter of brushwood, which detains the greater impurities, into coolers, from which, when quite cold, it may be drained into smaller casks. Various driers are employed for purifying whale oil and diminishing its unpleasant smell. The quantity of oil obtained is about four-fifths that
of the blubber used. In the South-Sea fishery it is found
advantageous to boil the blubber in water, and whaling vessels,
and to bring home the oil alone in casks. In this process, as
commonly performed, the oil is very imperfectly extracted
from the blubber, and the scum, or solid portions which remain,
are usually thrown into barrels; the nature of which arrangement
the oil that remains in them is not only destroyed, but also becomes,
from its great inflammability, a source of serious danger. To
obliterate these evils some ships are provided with powerful screw-presses for squeezing out
whatever oil may remain after the process of boiling the
blubber, and thus materially increasing the produce. Hebert,
in the 'Engineer's and Mechanic's Encyclopedia,' vol. ii.
p. 476, says: 'After some time the blubber, or thick
press, in which the blubber-scrapes are put into a hollow cy
linder, while yet warm, and compressed by a piston brought
down upon them with a great force. The oil escapes through
holes in the bottom of the cylinder, between which and the
blubber is laid a mattress of wicker-work, to prevent the
blubber from choking the holes. This press is the inven
tion of Mr. John Hythe, of Limehouse.'

Olive oil, as explained under Olea Europaea, in P. C.,
differs from most vegetable extracted oils in being extracted
from the soft fleshy pericarp, whereas such oils are usually
procured from the seeds only. The manufacture is very simple, and
requires little or no power; but writers differ in their accounts of the process, in some im
portant particulars; some stating that the fruit should be
gathered a little before it is ripe, and spread on the floor of a room,
and turned every day until the oil, while still warm, is put
in the volume on 'Vegetable Substances used as Materials of
Manufactures,' in the 'Library of Entertaining Knowledge,' it is
stated on the authority of an English gentleman who had
resided at Gallipoli, where much excellent olive oil is made
intended by the Philippians never gather the olives, but allow them to
drop in their maturity from the tree to the ground. In the
'Dictionnaire de l'Industrie,' published at Paris in 1795
vol. vi. in a section on the manufacture of olive
oil in Provence, however, it is stated that fallen olives should
not be mixed with those which are gathered, for fear of impart
an earthy odour to the oil, and a caution is given against allowing the heap of gathered olives to heat or ferment,
coupled with the remark that the sooner the olives are taken
to the mill the better will be the oil. According to this au
thority, also, all leaves should be carefully removed, as their presence would give a bitter taste to the oil. But Dr. Ure,
in the 'Dictionary of Arts,' &c., p. 898, writing of the same
district, states that it is usual in the neighbourhood of Aix, in
Provence, 'to preserve the olives for fifteen days in barns or cells,
and then, in the month of D.' in the manufacture of olive-oil in Provence, however, it is stated that fallen olives should
not be mixed with those which are gathered, for fear of impart
an earthy odour to the oil, and a caution is given against allowing the heap of gathered olives to heat or ferment,
coupled with the remark that the sooner the olives are taken

stones are mounted on the same horizontal axis, but at rather different distances from the central vertical shaft or axis round which they roll, so that they do not follow one another in precisely the same path on the bed of this mill. The bed is surrounded by a rim which prevents the seeds from being scattered by any eccentricity of the running stones. The two running stones are mounted carriers also take rakes or sweeps, which collect and lay the seeds in a ridge along the circular path of the runners. By this means the seeds are reduced, by the partial oil, without loss of the oil. A preparation of from which a limited quantity of very fine cold-drawn oil may be obtained by the simple action of the press.

Owing to the extreme hardness and smoothness of the seeds of cast-iron plates, the circumstance that the fragments of their shells, however broken, form minute concavities which will retain the oil unless a greater pressure be applied than could be given by an ordinary screw-press, the presses employed for extracting oil from such seeds differ materially from those used in crushing olives and other comparatively soft oleaginous substances. Hence it is that the wedge-press and Bramah's hydraulic press have been introduced for the purpose, and that of these two powerful machines some manufacturers prefer the former, believing that the same degree of pressure is more efficient when imparted by means of slender limbs of wood by means of which the pressure is transmitted gradually and steadily as in the hydraulic press. In the wedge-press, of which there are many varieties, the crushed seeds are put into bags of hair-cloth or some similar material, which are placed between plates of iron united together like the covers of a book, or between boards or blocks of wood, within a very strong and massive framework. The small end of a wedge is then introduced in such a way between these plates or boards that when it is driven down by the blows of a ram or pestle, it may compress the bags with enormous force. Barlow, in his 'Treatise on Manufactures and Machinery,' in the 'Encyclopaedia Metropolitana,' in which work (sections 504—515) is much important information on the subject of this article, states that the driving of the wedges is continued until they are so tight that the pestles rebounds from them three times, when attention is paid to the action of the screw. The use of the hydraulic press instead of this apparatus needs no minute explanation. In Barlow's work, just referred to, is an account of such a press which acts horizontally, the bags being, as in the wedge-press, placed vertically, and separated from one another by cast-iron plates; but in Dodd's account, above noticed, of the Walker oil-mill, the bags are represented as piled upon one another in cast-iron cases, and placed in a vertical press. Dodd speaks of the bags in which the seeds are contained as of flannel, and Barlow as of woolen, 'unfolded (enfolded?) by horse-hair mattresses, enclosed in leather wrappers.' The last-mentioned writer states that the first operator of this machine was constructed at Bremen, in 1821, and that its proprietor is satisfied of the superiority of the plan to any other then in use. Among other advantages it is stated that the hydraulic press requires no stamping, as the seeds could do the same work, and that the hairs and bags are found to last longer with it than with the old machine. Since the above date the Bramah press has been successfully applied in the manufacture of cocoa-nut oil, and several presses have been exported to Ceylon and other places for that purpose. Mr. John Hall, of Dartford, patented in 1829 an ingenious oil-press in which the power of a steam-engine or other prime mover is applied through the medium of cams or eccentric rollers; but Barlow states that the plan has not been generally adopted.

We have hitherto spoken only of the extraction of the oil. The means employed before pressing is however necessary for obtaining the principal supply of oil. The precise order of the several operations, as well as the nature of the machinery employed, differs in different places. In the pressings by Barlow the oil-cakes, or solid contents of the bags, which remain after the first cold pressing, are taken out of the bags, broken to pieces, and put into mortars to be pounded by pestles with water. 'There,' he says, 'the pattern is again broken down, and the parestchyma of the seed reduced to a fine meal; thus free egress is allowed to the oil from every vestige in which it is contained, but it is now rendered more serviceable by being passed through a strainer, and even of the fine parts of the meal.' When sufficiently heated it is removed to a chamber, or circular copper pan, in which, while it is kept continually stirred by machinery, it is heated to about the temperature of melting beeswax, either by a charcoal fire, or, according to a more recent practice, by steam. It is then, while hot, put into the bags and subjected to a second pressing; and in some cases the like operations are repeated at least a second time. A second press of inferior quality, is produced. Sometimes the produce of oil is increased by mixing a little water with the paste; but this process is considered to impair the quality of the oil. The oil-presses from Mosop, in particular, which have no other employment than extracting oil from the cakes which they purchase from the French and Brabanters, after passing the process of their mills; a clear indication of the superiority of the Dutch practice.' In some of the Dutch mills, we learn on the same authority, the produce is increased by the application of moderate heat during the grinding process, by enclosing a little furnace in the bed upon which the running stones roll; but it is observed that 'the utmost care is necessary to prevent the heat from becoming too considerable, as it causes the oil to dissolve too much of the fermentable substance of the seeds and exposes it to the risk of soon growing very rancid. When the heat is kept out of the process of grinding may be facilitated by the addition of a little water. The oil produced by the above process needs little further treatment, as the same is unseparated, as it is delivered by the Dutch manufacturers, the parenchymatic part, which inevitably passes away with the oil in some degree in the operation of pressing, will gradually subside, and the oil may be drawn off at very small loss. In drying, great care must be taken, as the bottom being at length removed to a drier and narrow cauldron, where it should be left a considerable time for the dregs to subside.

Linseed oil is used principally as a vehicle for mixing oil-colours for painting, but it is also valuable in several branches of manufacturing industry, and, in a refined or purified state, in some medicinal preparations. Being a fat or oil, it does not easily evaporate, but it is a great inconvenience in some purposes in painting, it is sometimes converted into drying oil by boiling it with sugar of lead, white vitriol, red lead, or other substances which possess similar properties. The common kinds of drying oil are generally known by the name of boiled oil.

Very full details of the improved modern machinery used in the manufacture of oil from seeds are given by Barlow, in the work above quoted, in Dr. Ure's 'Dictionary of Arts, and in the Supplement to that work; and some ingenious processes of simpler character are described in Hebert's 'Engineer's and Mechanic's Encyclopedia;' and in both of these works additional details of the construction of these apparatuses are given, to which the generally important character. The process of making castor oil is detailed under Richius COMMUR, P. C., p. 5, 6.

O'KEEFE, JOHN, was born at Dublin, on the 24th of June, 1747, his father being a man of some consequence in the city, when only six years old, under the charge of Mr. West at the Royal Irish Academy; and his literary education, in Greek, Latin, and French, was received from Father Austin, a learned Jesuit, and his family being Roman Catholics. Two years of his youth, beginning when he was about fifteen, were spent in London with an uncle. From early boyhood he had dabbled in versification; at the age of sixteen he had composed a comedy, and when he was no more than eighteen another comedy of his was brought out by Mossop, at the Smock-alley Theatre in Dublin. His dramatic turn now took entire possession of him. He obtained an engagement at Mossop's Theatre as soon as he was of age for some years to be a member of the company; acting both in Dublin and in other towns of Ireland. At the same time he exercised himself in dramatic writing, often producing small pieces for his own benefit, and on other occasions. In 1747 he married a daughter of Mr. Heaphy, proprietor of the Theatre Royal in Dublin, by whom he had three children. Domestic disagreements arose: after seven years of union Mr. O'Keefe left her, taking her daughter with him, and in 1771, on his separation from his wife, he removed to London; and he never again visited his native country. From that
time he was a play-writer by profession. The greater number of his performances appeared at the Haymarket; but he wrote frequently also for Covent Garden under the management of Harris. His dramatic career may be said to have closed in 1788, after which date no new play of his is known to have been written. But his labours were a collection of dramatic pieces, amounting, on his own list, to no fewer than sixty-eight, of which fifty-six were acted, and many of these with great success. Some of them still keep possession of a substantial literary reputation. His works are mere farce; but the best of them have a flow of spirits, a kindness of feeling, and a richness of whin and eccentricity, which account adequately for the popularity they so long enjoyed. They were composed in circumstances calling for much indulgence. They were the constant efforts of a very poor man to preserve himself and his children from beggary. And, further, from his twenty-eighth year, when a neglected cold brought on inflammation of his eyes, he suffered under a gradual decay of sight, which speedily made reading and writing alike impossible. He was never entirely blind; but for many years he could do little more than distinguish light from darkness.

In 1780, Mr. Harris gave him a benefit at Covent Garden, at which he himself appeared, and the money realized in the subscription and the receipts was enabled to spend 800l. in purchasing a small annuity. In 1803 he received a life-annuity of twenty pounds from Covent Garden, nominally as the purchase-money of his drama still unprinted; but this annuity ceased to be paid in 1826. In 1806 he began to receive a pension from the Crown, to which another pension of a hundred guineas was added in 1826. From these combined sources he was, during the last years of his life, supported in an income little exceeding two hundred a-year; and, in an honourable spirit of independence, he refused a donation sent him by the Literary Fund Society. In 1836 he published 'Recollections of the Life of John O'Keeffe, written by himself.' two volumes 8vo. In 1828 he removed from the neighbourhood of London to Southampton, and there resided thenceforwards, attended by a daughter, who was his only surviving child, his eldest son, a clergyman of the Church of England, having died of the yellow fever at Jamaica, in 1804. O'Keeffe himself was a Roman Catholic to the last. He died at Southampton, on the 4th of February, 1838. In 1834 appeared a small volume of elegies, 'To the Baron Zach, and to Lady Leggatt, addressed to his Daughter,' and prefaced by notices of his character and domestic circumstances.

OIBER, HENRICH WILHELM MATHIAS, an able astronomer and mathematician of Germany, was born October 11, 1768, at Arbergen, near Bremen. Of his private life few particulars have yet been made public; and almost all that can be stated respecting the history of this celebrated person is contained in isolated notices relating to his discoveries in the heavens. He studied medicine at the University of Göttingen, and, during all his life, his time appears to have been divided between the exercise of his profession and his astronomical researches: it is said that, in 1830, he celebrated, by a public festival, the fiftieth anniversary of his medical labours; and his observatory is described as the most complete of those which, at the time of its latest existence, existed in Germany. It consisted of three rooms in the upper part of the house, which was situated in the heart of Bremen: three great windows in the south front gave a view of the heavens almost to the horizon on that side, and one in a closet enabled the observer to look towards the north: openings in the ceiling and roof permitted observations to be made near the zenith. Oibers possessed a five feet achromatic telescope, with a position micrometer by Dollond, and a reflecting telescope of equal length by Schröter: he had also, an astronomical clock by Karsten, a quadrant by Bird, and a reflecting sextant by Troughton, but he had neither a transit instrument nor a mural circle; and, apparently, he determined the time by extra meridional altitudes. Attached to the observatory was an astronomical library containing, among other valuable works, an extensive collection of documents relating to cometography: this library was, after the death of Oibers, presented to the university of Breslau, and deposited in the observatory of Pulkowa.

Dr. Olbers wrote but little on the subject either of medicine or astronomy; but, in 1780, he printed a thesis entitled De Oculi Musculorum Motibus, in which he shews how the eye accommodates itself to the different distances of objects from it by means of a variable action of the muscles, in consequence of which changes are produced in the convexity and the focal length of the cornea; and in 1829, he published in the Annuaire du Bureau des Longitudes a memoir entitled 'De l'influence de la lune sur les saisons et sur le corps humain.'

In 1779 he became known to astronomers by a series of observations which he made on the comet of that year, and by his determination of the elements of its orbit: the computations were founded on a method which had been given by Euler: but, not satisfied with this, he applied to a new method of calculating the orbits of comets from three observations, which, with respect both to facility and accuracy, he considered as having great advantages over the methods before in use. An account of this method, with a preface by the Baron de Zach, was published at Weimar in 1797. It is entitled Abhandlung über die leichteste und bespanneste methode die Bahn eines Cometen aus einem Beobachtungen zu berechnen, and it affords sufficient evidence that the talents of the author as a mathematician were considerable. An outline of the method, with its application to an example is given in Abhandlungen aus dem Königlichen Astronomischen Seminer zu Berlin (vol. iii. Nos. 184, 243, &c.) Oibers computed also the elements of the comets of the years 1781 and 1795; those of two comets which appeared in each of the years 1798 and 1799, of one in 1803 and of the great comet of 1611.

The interval between the orbits of Mars and Jupiter, which appears disproportionately great when compared with the intervals between two or the other planets belonging to our system, had suggested to the original and inquisitive mind of Kepler the idea that a planet too small to be seen from the earth, existed in that region: the idea appears to have been little regarded till M. Bode, of Berlin, obtained his empirical formula, for the distances of the planets from the sun, which, except with respect to the distances of the planets from Mars and Jupiter, was found to hold good for all the known planets, including the Georgian; when that which was before considered as the vision of an enthusiast was found to be deserving of serious consideration. With a view, therefore, of ensuring, as far as possible, a complete examination of the heavens in the parts where the supposed planet might be expected to be found, M. Schröter was induced to form an association of twenty-four astronomers, who, having divided the heavens into as many zones, were each to confine his observations to one of them. That distinguished individual was chosen President, of the 'Boden dasselbe, and the Baron Zach, of Vienna, of Legge, of the 'Board of Observers': the labours of the association were not, however, immediately rewarded; and M. Piazzi, of Palermo, who was not one of the number, had the good fortune to discover on January 1, 1801, at his observatory at Palermo, the planet Ceres, and which was found to be between the orbits of Mars and Jupiter, at a distance from the sun nearly equal to that which, in conformity to the law discovered by Bode, it ought to have occupied.

This planet soon afterwards became invisible, from its vicinity to the sun; but Dr. Oibers and M. Gauss, having calculated its orbit approximately from such observations as had been obtained, sought for it at the time when it was expected again to appear, and the former was the first to re-discover it. The idea of Kepler and the formula of Bode seemed now to be fully confirmed; but the harmony conceived to exist in the planetary distances was almost immediately, in appearance, deranged; for on the 28th of March, 1802, Dr. Oibers, being engaged in examining the northern part of the constellation Virgo, discovered a star which was not in any of the catalogues previously made up. On January 31, 1807, it received the name of Pallas. Its orbit was soon calculated, and it was found to describe a very eccentric ellipse about the sun at a mean distance from it which is nearly equal to that of Ceres: the time of its ascending node is also very similar to that of Ceres; and its plane of revolution is almost the same as that of the last-mentioned planet, but it has a much greater inclination to the plane of the ecliptic. Dr. Olbers was led, from the fact that these two planets are nearly in the same plane of space, and because some parts of space are very rarely traversed by the planes of the orbits intersect one another, to imagine that they might be dispersed fragments of a large planet which revolved, at one time, about the sun at nearly the same distance from it as Ceres, and at another time, by some great revolution or from some other cause, had been broken up. Pur-

TO this idea, he considered that there might be other fragments, or small planets, in the same region; and the idea was strengthened when, in September, 1804, a third planet of a like kind was discovered by M. Harding of Bremen. This planet, which was named Juno, has the nodes of its orbit nearly coincident with those of Pallas, so that the two planets are also nearly equal to one another, and both planets revolve about the sun at nearly the same distance. Dr. Olbers now determined to make the discovery of new planets the principal object of research; and from 1807, he persevered in examining with the most minute attention, at the times of their opposition to the sun, the parts of the heavens which were near the nodes of the three other planets. In March, in the latter part of the year, his sagacity and diligence were rewarded by the discovery of a fourth planet; on the 3rd of April he sent intelligence of the event to his friend M. Bode, and he transmitted the series of his observations to M. Gauss. The latter astronomer immediately computed the figure of the orbit, and, Olbers having requested him to give a name to the planet, he designated it Vesta. This is the smallest of the four new planets, or asteroids, as they have been designated, and the time of its revolution about the sun is the shortest.

It may be proper to mention, in this place, that additional confirmation of the opinion of Olbers has been afforded by the discovery of a new planet on the 5th of December, 1845, by M. Hencke of Drissen, and it has received the name of Astraea; it is a small planet, and revolves about the sun, between the orbits of Juno and Vesta, in about four years.

In 1815 (March 6th) Dr. Olbers discovered, near the constellation Perseus, a comet which presented the appearance ofSidney without a train. It was supposed to be continued to observe it till the end of August, when it ceased to be visible: its orbit was calculated by Beselli and Gauss, and it was found to accomplish its revolution about the sun in 73 years. In 1826, he published a dissertation on the probability that the comet may come in collision with the Earth—a subject which then engaged the attention of astronomers on account of the near approach of the comet Biela when in one part of its orbit in 1834. He forwarded a proposal for a reformation of the constellations and a revision of the nomenclature of the stars; recommending, as models, the figures in Flamsteed's Atlas, but better drawn than they are in that work, and also that the representations of persons and machines which have no relation to astronomy should be cancelled.

Dr. Olbers was elected a fellow of the Royal Society of London, 1804, and a Foreign Associate of the Académie des Sciences at Paris in 1829: he was also a corresponding member of several other learned societies, a knight of the order of Dannebrog and of the Red Eagle of Prussia. He died at Berlin on the 7th of March, 1840, at a proof of his fame and his high citizens of Bremen placed his bust in the public library of the city.

**Biographie Universelle. Supplement. Monthly Notices of the Royal Society.**

OLDMIXON, JOHN, one of the heroes of the Dunciad, was born in 1678. The place and kind of his education are unknown. His authorship appears to have begun with the drama, in which he was utterly unsuccessful; and his principal productions were historical, political, and critical. He overintended, carelessly and unfaithfully, the first edition of the collection of English historians which bears the name of Bishop Kennett. He himself wrote also 'A Critical History of England', 'The History of England during the reigns of the House of Stuart', and 'The History of England during the reigns of William and Mary, Anne, and George I'. It is large and undercumbersome, and is chiefly remarkable for their strong spirit of Whig partisanship. In criticism Oldmixon was distinguished for his unscrupulous abuse of Pope and other eminent men of his day. He found abundant material for venting his animosities, not only in continual criticism, but in his 'Prose Essay on Criticism', and his 'Arts of Logic and Rhetoric' (a clumsy adaptation from Bouhours). His party-services were rewarded by an appointment to the Board of Commissioners for the Port of Bridgewater. He died in London, in 1742.

**OMBRO-METER. [RAIN GAUGE, P. C.]**

**OMBRO-METER. [RAIN GAUGE, P. C.]**

**OMNIA**

**OMNIA**

**OMNIUM**

OMNIUM, employed in the Stoic philosophy, to express the value, taken as an average, of the different stocks in which a loan is usually funded. Thus, a loan having been contracted for on a certain day, an average is made of the stocks in which such loan is contracted, at the price which they bore on that day, and the fund thus formed as an average of the whole is called Omnium. (Mr. Colloquy's Dict. of Com.

**ONAGRA. [ESOTHEKA, P. C. S.]**

**ONAGRA. [ESOTHEKA, P. C. S.]**

**ONATAS (Ovand) of Aegina, the son of Micron, was alike distinguished as a painter and a sculptor: he was contemporary with Polygnotus, and lived accordingly in the early part of the 5th century before the Christian era. His name does not occur in Pliny, and, with the exception of an epigram upon a statue of Apollo by him, in the Greek Anthology, he is noticed only by Pausanias, who also gives us an account of his life. He was, however, in terms of great praise. Pausanias speaks of a group of Hymenacius heroes near the great temple at Olympia, which were dedicated by the Achaeanas in common; Thiersch attributes them all to Onatas, but his name was inscribed on one only. Pausanias says that the Achaeanas in common dedicated those statues which represent the Greeks who drew lots for the challenge of Hector; they stood armed with spears and shields near the great temple; opposite to them was Nestor with the lots in a helmet. There were eight besides Nestor; the statue of Ulysses, which made the ninth, and had been removed by Nero to Rome. Of the remaining eight, on the other hand, five werekeys, and his name is inscribed upon it, and it was written from right to left. On the shield of another was represented a cock, and this, says Pausanias, was Idomeneus, the grandson of Minos. In the interior of the shield was an alluding inscription, which appears to apply to the statue of Idomeneus alone:

**ΠΑΛΛΑ ἂν θεῷ αὐτόν μοιράσαι καὶ ἄν' ὄντες **

**Εὔρος, ἐν ἔφερεν τὸ τέμπλω μετὰ Μίνω.**

As well as many others, this is the work of the aulic Onatas. Micron was his father, his birth-place Aegina.

The Thasians also dedicated a bronze statue of Hercules by Onatas at Olympia, with a club in his right and a bow in his left hand; it measured ten cubits, and the name of Onatas with his birth-place and parentage was inscribed upon it. Pausanias observes with respect to Onatas that he was not surpassed by any artist that had appeared in the school, or from the workshops, of Attica, since Daedalus; that is, from Daedalus to Onatas's own time, which was shortly before Phidias.

Pausanias mentions further, by Onatas, at Olympia, a Mercury carrying a ram under his arm; he had on a helmet and a cloak besides a tunic or under robe; he was assisted by Callitēs, whose Pausanias supposes to have been the son or pupil of Onatas.

Onatas cast also in bronze a statue of Ceres the Black, or Demeter Melaina, for the Phigalians, in the place of an old wooden image which was destroyed by fire. Onatas cast the new statue, but when it was delivered he refused to accept one, assisted by a vision in a dream: it had a horse's head. He made also a statue of Apollo, at Pergamum, magnificent for its size and its workmanship.

Onatas had also the bronze charter of Hiero, dedicated by his son Deinomènes at Olympia in honour of his father's victories in the games: the horses and riders were by Calamis. He made also, together with Calyntus, an artist otherwise unknown, the monument dedicated by the Tarentines at Delphi: they sent a tenth of the spoils taken from the Peucetii, a neighbouring barbarous people. The offerings consisted of several figures of warriors on foot and on horseback: Opis, king of the Lacedæmonians, who assisted the Peucetii, was represented dying; near him stood the hero Taras, and Phalanthus, by whom was a dolphin; Phalanthus was saved from shipwreck in the Crissaean sea and brought on shore by a dolphin.

Onatas is mentioned only once as a painter: he decorated with Polygnotus the walls of the vestibule of the temple of Minerva Areia at Plataea. Onatas painted the most beautiful picture which has been preserved in art. Thus also he painted at Plataea the picture of Euryganea lamenting the death of her sons Eteocles and Polyneices killed by each other's hands; which, according to Sylliburgus, is by a MS. error, attributed to Calyntus; but he ascribes it to Onatas. Micron, the father of Onatas, was the celebrated Athenian painter of that name.

(Pausanias, v. 25, 27, vii., 42, vi., 12, 18, ix., 4, 5, Junius, Justin. Censor. SCHRIFTE, THIERSCH, Epoche der Bildenden Kunst unter den Griechen; Böttiger, Ideen zur Archäologie der Malerei.)
ONO, or ANGOLE, a town of Hindustan, in the Presidency of Madras, and Northern Carnatic. (Carnatic, P. C. H.) One of the largest and wealthiest towns in the province. It is situated in 15° 31' N. lat., 80° 1' E. long., 173 miles N. by W. from Madras. The sovereignty of the district and town of Ongole was acquired by the East India Company in 1823, by treaty with the Nawab, to whom it previously belonged. The town was then strongly fortified, but the fortifications have been suffered to fall into decay or have been destroyed.

(Don's Eastern India Gazetteer.)

ONOBYCHIS (from ονοβ, an ass, and ὕπαυξι, to graze the teeth), a genus of plants belonging to the natural order Leguminosae. It has a calyx with five nearly equal subulate teeth, exceedingly long, longer than the wings; the pod one-celled, compressed, indehiscent, one-seeded, upper suture straight, lower curved, toothed, winged or crested. The species of this genus are natives of Europe or Asia, with unequaly plane leaves, and axillary elongated pedicels having spikes of flowers red or white at their tops. The most common, as well as only British species is Onobyclus satina, common Sainfoin. (Sainfoin, P. C. H.; Hedbarum, P. C. S.) About forty other species have been described, but none of them possess useful properties. Many are showy plants when in bloom, and are adapted for flower borders or rockwork. They may be propagated by seeds.

(Onobyclus's Dictionary; Babington's Manual of British Botany.)

ONONIS (from ονον, an ass, and ονον, to delight, of some of the species being said to be grateful to ass), a genus of plants belonging to the natural order Compositae. It has a silky cleft campanulate calyx, narrow segments, the lower ones longer. The keel is beaked, the style filiform and ascending, the stigma terminal and subapetalous. The flower stalks are hairless, the stem is more or less pubescent. There is a procumbent uniformly hairy stem, axillary stalked flowers, broadly oblong leaves, ovate pods shorter than the calyx. It is usually without spikes. The stems root at their base, and the seeds are tubercular.

O. antiquorum has an erect or ascending stem, bifurcately hairy; axillary stalked flowers, oblong leaves, and ovate, erect pods longer than the calyx. It is doubted by many botanists as to this being true O. antiquorum. Koch and Reichenbach both describe quite a different plant, with smooth seeds.

O. recta has a viscid pohsecestem, axillary flowers with one flowered pedicles shorter than the leaf flower, a pod without bracts, the corolla about equal to the calyx, oburate, lanate leaves serrated at the lip, ovate stipules, and cylindric reflexed pods. It is found in sandy places in Galloway and the Channel Isles, and in the south of France by the sea coast.

There are 107 species of this genus described, but none of them are used in medicine or the arts. They are chiefly native to Europe and Asia, and a few on the coast of Asia. They are generally handsome when in flower. The hardy shrubby kinds are increased by seeds and layers, the hardy perennial kinds by dividing the roots in the spring, or by seeds. These are well fitted for flower borders. The seeds of the hardy annual kinds only require to be sown in the open border in April. The greenhouse and frame species thrive well in a mixture of loam, peat, and sand; these are usually increased by seeds which ripen in abundance.

(Ononis's Dictionary; Babington's Manual of British Botany.)

ONOPODURUM, a genus of plants belonging to the natural order Compositae. It has a honeycomb receptacle, a fourribbed fruit, and an imbricated involucre, with simple spinous pappus scales.

O. Acanthium, Cotton-Thistle, has an erect many-headed stem, elliptic oblong leaves, woolly on both sides; serrate, spinous, and depressur; the outer involucral scales lanceolate, subulate, recurved, and spreading. The stem is from four to five feet high. (S. & G.) The flower head is from 2 to 3 inches in diameter. The flower is lucre nearly globose, large, and somewhat corymb; the scales fringed with spinous teeth; the florets are purple. This plant is found on waste ground in Great Britain and Spain. Another name for the same species is Widow's-Artichoke, or Alcachofa of the Spaniards, on account of the fleshy receptacle being once cultivated as an esculent vegetable. The expressed juice of this plant is said by Eiller to be a serviceable emollient for the breast, and to cleanse foul ulcers; and a decoction of the root, which is siringent, has been used to restrain discharges from the mammary membranes. The seeds are used as an infusion, as the result of experiments, that 22lbs. of onopordum heads will yield 12lbs. of seeds, from which 3lbs. of oil fit for burning may be extracted by heat.

(O. obtusifolium's Manual of British Botany; Burnett's Outline of Botany.)

ONOSMA (from ονοσμ, an ass, and σμα, smell; grateful to the ass), a genus of plants belonging to the natural order Boraginace. It has a five-parted calyx, a tubularly campanulate corolla, and a naked throat. The anthers are agglutinate, and connected together by the bases of the lobes. The nuts are ovate, strong, and fixed to the bottom of the calyx, unperforated at the base, indefinite at the apex. The speck is small, and of plants, with crowded lanceolate or linear leaves, and terminal racemes of large yellow second and usually drooping flowers.

O. Emodi has lanceolate three nerved leaves, less hairy beneath, terminal solitary racemes, linear bracts, not half so long as the flowers; the calyx is five cornered with ovate segments, a ventricose five-keeled corolla contracted towards the mouth, and the anthers longer than the filaments. It is native of Nepal, in Chosinathan, where it is called by the natives Maharanja. The root is bruised, of a dark purple colour, and is used in dyeing.

O. schinum is a hirsut plant, covered with white pentgent hairs. It has a long graceful and pedicellate flowers. The corolla is yellow, a little longer than the calyx, tubularly campanulate with reflexed teeth.

O. sarmentosum is native of Tauria, in the vicinities of the Bosphorus. This species is very common, and is a shrub, black and covered with a red pigment, which stains paper a violet colour.

All the species of this genus, which exceed thirty in number, are extremely handsome when in blossom, but are not valuable on account of any peculiar properties. Most of them are natives of rocks and sandy places in Europe and Asia, and answer well to grow in rock work or wall tops. They are short-lived, and apt to rot. They do well, however, in small pots among other shrubs and plants.

(Don's Gardener's Dictionary.)

OSTEHERIUM, situated in 51° 30' N. lat. and 4° 52' E. long., is a market-town in the province of North Brabant, in the kingdom of the Netherlands. The population is about 8000 inhabitants. There are numerous potteries, brick-kilns, and three annual fairs for cloth, linen, and shoes.

Stain, Leiden; Hassel, Handbach; Cannich, Laubach.)

OPACITY is a condition of bodies under which they are incapable of transmitting light through them. It seems to depend upon the nature or disposition of the particles of bodies, but its precise cause is, at present, far from being understood. According to Natta, opacity may be due to the presence of a solid layer of a homogeneous nature, as glass, diamond, &c., the light experiences so much less of these irregular actions that, except when the thickness of the medium is very great, it is enabled to pass quite through them.

The entire absorption of all the light which enters a substance, merely by the multiplied refractions or reflections which it undergoes within the mass, is difficult to conceive; and the advocates of the undulatory theory ascribe opacity to the unfitness of the pores, or intervals between the particles of a body, for permitting the vibrations of the particles of ether, and consequently for continuing in the interior the existence of the waves which are incident on its surface. The same persons consider transparency to consist in such a disposition of the particles of a body that the incident waves of ether can be propagated with a certain degree of freedom through the mass: some impediment to the propagation of the waves may exist in the most transparent substances; and hence when such substances have more than a certain thickness, the waves cease to be transmitted through them. (Transparency, F. C.; Absorption of Light, F. C.)

OPERATION. In this article we intend to point out the principal steps of the application of the calculus of operations [Operation, F. C.] to the solution of differential equations and equations of the highest orders. The following are the steps which must be carefully read before the present one, and also the general principles laid down in Algebra, F. C. S.

However much the calculus of operations may throw light upon the character and principles of algebra, its application is at once

P. S. No. 173.

Vol. II.—3 C
time have been thought unlikely that it should much facilitate actual processes. It does this, nevertheless, and nowhere more than in the subject we are now going to describe.

Solutions which by the usual method \( [\text{VARIATION OF PARAMETERS}] \), P. C. S., would never have been considered fit examples for an elementary work, on account of their complexity, may be represented with ease, and obtained in full with very little trouble.

When rules of algebra are true of the meanings of any symbols, all consequences of the use of these rules, all relations which are legitimate deductions from them, also represent truths. Not that these truths are always intelligible without subsequent interpretation; nor do we mean to say that, in the present state of the science, the interpretations are always attainable. And further, it may happen that theorems can be pointed out, derived from processes in which some only, and not all, of the fundamental rules of algebra are true. This does not prevent our right to deduce conclusions from such theorems, as long as we use no fundamental rules except those which are true of the expressions in question. For instance, we have seen that the operations of our calculus are not convertible with the operation of multiplying by a function of the variable. Thus if \( E \) stand for the direction to change \( x \) into \( x + 1 \), \( D \) for that of forming the difference which arises, and \( L \) for the direction to take the differential coefficient with respect to \( x \), we have no right to say

\[
E \frac{\partial f(x)}{\partial x} = E \partial f(x), \quad \frac{\partial f(x)}{\partial x} \neq D \partial f(x), \quad \frac{\partial f(x)}{\partial x} \neq D f(x) \quad \text{in which } x \text{ is a function of } x.
\]

It is the operation on \( x \) alone, this convertibility of operations is the only rule of algebra which fails; it is therefore the only one the use of which we must avoid.

The operations \( E \), \( L \), and \( D \) are closely connected with \( E^a, L^a, D^a \), of which they are particular cases; a being a constant, positive, negative, or nothing. We have

\[
\begin{align*}
(E-a) f(x) & = e^{a(1)} \Delta(\Delta-a) f(x) \\
(D-a) f(x) & = e^{a(2)} \Delta(\Delta-a) f(x)
\end{align*}
\]

The first sides of these equations being representations of \( f(x-1)-ax, \Delta f(x), \Delta f(x)-ax, \) and \( \Delta^2 f(x)-ax \). If these operations be repeated, we have

\[
\begin{align*}
(E-a)^n f(x) & = e^{a(1)} \Delta^n (\Delta-a) f(x) \\
(D-a)^n f(x) & = e^{a(2)} \Delta^n (\Delta-a) f(x)
\end{align*}
\]

These results will also be found to be true when \( m \) is negative, by which means we are enabled to interpret \( (D-a)^{-1} \), \( (D-a)^{-1} \), and \( (E-a)^{-1} \) and their repetitions.

These same forms may be extended, as follows: Let \( E_x \) and \( E_y \) severally denote the operations of changing \( x \) into \( x + 1 \) and \( y \) into \( y + 1 \); and let \( D_x , D_y , \Delta_x , \Delta_y \) be similarly interpreted with respect to the differentiations and differences. We have then

\[
\begin{align*}
E_{x-a} \cdot E_{y-b} f(x, y) & = e^{a(1)+b(1)} \Delta_x \Delta_y \Delta_x^a \Delta_y^b f(x, y) \\
(D_{x-a} \cdot D_{y-b}) f(x, y) & = e^{a(2)+b(2)} \Delta_x \Delta_y \Delta_x^a \Delta_y^b f(x, y)
\end{align*}
\]

in which the function first operated upon is left out to save room. Here \( m \) and \( a \) may be either positive or negative integers. And even \( m \) or \( a \) may be symbols of operation, but not with respect to \( x \) and \( y \) respectively.

\[
(D_{x-a} \cdot D_{y-b}) f(x, y) = e^{a+b} \Delta_x \Delta_y \Delta_x^a \Delta_y^b f(x, y)
\]

in which the function is not altered, but the variables are changed. Interchanging \( y \) into \( y-\alpha y \), differentiate \( m \) times with respect to \( x \) and \( y \), change the order of the terms.

The results we shall give shall be the heads of some methods of solution, observing that this article is intended only for those who can already master the same solutions by other methods.

Take the common linear equation

\[
d^y y + a_1 d^{a-1} + \ldots = 0
\]

in which \( a \) and \( b \) are constants, and \( x \) a function of \( x \). The operation performed upon \( y \) is \( aD^b + bD^{a-1} + \ldots \); if this be called \( G \), then \( y \) is the result of performing the inverse operation

\[
G^{-1} \quad \text{upon } x.
\]

By the method explained in \textsc{Fractions}, \textsc{Decomposition of P. C. S.}, transform \( (aD^b + bD^{a-1} + \ldots)^{-1} \)

\[
A(D-a)^{-1} + B(D-b)^{-1} + \ldots = 0
\]

into \( A(D-a)^{-1} + B(D-b)^{-1} + \ldots = 0 \), \( \alpha, \beta, \ldots \) are the roots of the algebraical equation \( a \alpha^n + b \alpha^{n-1} + \ldots = 0 \).

Then \( y \) is

\[
A(D-a)^{-1} X + B(D-b)^{-1} X + \ldots = 0
\]

or \( A \ast f(x) \ast X + B \ast f(x) \ast X + \ldots = 0 \), substituting for \( f(x) \) its usual mode of expression. The arbitrary parts of the solutions will be obtained by the constants of integration in the usual manner. But the arbitrary part will always be obtained, in all inverse operations, by considering the function operated upon as \( X+0 \), and operating separately upon \( X \) and \( 0 \). Thus \( (D-a)^{-1} X \) may be completely expressed by

\[
\ast f(x) \ast X + \ast f(x) \ast X = 0,
\]

the second term of which is \( \ast f(x) \ast X = P(x) + Q(X) \), \( P \), \( Q \), and \( R \) being any constants.

Suppose that there are equal roots in the above equation, say three roots equal to \( a \). The resolution of the fraction gives terms of the form

\[
K(D-a)^{-1} X + L(D-a)^{-1} X + M(D-a)^{-1} X
\]

which contribute to the general value of \( y \),

\[
\ast f(x) \ast X + \ast f(x) \ast X = 0
\]

and the arbitrary part \( \ast f(x) \ast X + \ast f(x) \ast X \).

The linear equation of differences corresponding to the above is

\[
\sum a_n x = 0
\]

where \( u \) is a function of \( x \) to be determined. The operation performed upon \( u \) on the first side is \( aD^e + bD^e + \ldots \)

Every single root \( a \) contributes to the solution a term of the form

\[
A(D-a)^{-1} X + B(D-a)^{-1} X
\]

in which \( \Delta x \) may be any function of which the difference is \( x \). If \( x \) is an integer, what is called \( 2(x-\alpha) \) will do.

Any set of equal roots contributes terms of the form

\[
A(D-a)^{-1} X + \Delta x = 0
\]

Any linear equation being given, in which either of the operations \( D_x, D_y \) or \( D_y, D_y \) is combined with either \( E_x, D_y \) or \( E_y, D_y \), the form of the solution may be found. Take for example

\[
\frac{d}{dx} u_x, u_y + ax + by = x
\]

the operation performed upon \( u \) on the first side is \( D_x - aE_x \) and accordingly we have

\[
u_x + u_y = e^{a+b} \ast f \ast x \ast d_{x+1} X
\]

which is one form of the solution, and must be interpreted by expanding

\[
e^{a+b} \ast f \ast x \ast d_{x+1} X
\]

Another form can be obtained from

\[
E_x - \frac{1}{a} D_y u_{x+y} = \frac{1}{a} X
\]

We can only touch very briefly upon these points, and rather to show the existence of the system than to enter into it. Further details will be found in the \textit{Library of Useful Knowledge}, in the \textit{Treatise on the Differential Calculus}, pp. 781-784.

The theorems answering to that of integration by parts, when \( D \) and \( E \) are used, are as follows. To save room let \( D = aE \) and \( E = aD \) be denoted by \( \alpha \) and \( \beta \). Then

\[
e^{-\beta} (Fg) = \alpha e^{-\alpha} e^{-\beta} (Fg)\]

\[
\Delta^{-\beta} (Fg) = P(a) - Q(a) - \Delta(a) P(a) - Q(a)
\]

\text{P and Q being functions of } x \text{, to which } D \text{ and } E \text{ refer, and } P \text{ meaning } \frac{d}{dx} \text{. If } a = 0 \text{, the first becomes}

\[
\int f d_{x+1} X = P(0) + \frac{1}{a} X
\]

which is the formula for integration by parts. And if \( Q \) be of the form \( \alpha P \), \( \alpha Q \), \( P \) and \( Q \) being a rational and integral function of a lower degree than the nth, the preceding opera-
tions carried on will show that \( e^{-1}(P_0 R) \) and \( A^{-1}(P_{AB} R) \) can be performed without leaving any trace of inverse operation in the result. Of the first of these it is a particular case that

\[ \int_{\partial D} e^R \, dx = 0, \]

an equation of the eighth degree. There are eight equations of the seventh degree. Two of them are discovered at once by performing the operations \((D-1)^{-1}\) \(\text{and } (D-2)^{-1}\) on both sides, giving

\[ (D-1)^{-1}(D-2)^{-1} = \frac{1}{A^2} \text{for } x^2 = 2x^2 \text{Sd}x, \]

and the operation must be repeated; and so on.

(See the Cambridge Mathematical Journal, vol. iv. pages 60, 96.) This work abounds in uses of the calculus of operations; it was here in fact that the late D. F. Gregory first introduced this branch of it. See also the Examples of the Differential Calculus, by the same author. Mr. Boole, in a recent volume of the Philosophical Transactions, has given great and ingenious extensions to the subject.

OPHIDIUM (from \( \text{ophis} \), a snake), a genus of malacostracous fishes of the Eel tribe. The species have smooth heads; long slender bodies, margined by the united dorsal, anal, and caudal fins. The jaws, palate, and pharynx are all furnished with teeth. The branchial aperture is large. The species vary in form and colour, and in the presence, absence, and number of the various organs of the internal organs, attached to the under jaw. Two species inhabit the British seas, but both are very rare. In the Mediterranean, the bearded ophidiidium is common, and is used for food.

OPHIOGLOMUS (from \( \text{ophios} \), a snake, and \( \text{glosa}, \) the tongue), a genus of plants belonging to the natural order Filices and the tribe Ophiodensae. The thecae are conolate, disposed in a simple distichous spike attached to an unarticled frond.

O. vulgaris. Adder's Tongue, is the only British species. It has an ovate oblong frond, and is from 4 to 12 inches in height. The spike is club-shaped, usually rather longer than the frond, sometimes very long. This plant is generally distributed over England, and in many places is exceedingly common, covering large plots of ground, and is highly injurious to the crop of grass. It is less frequent in Wales, Scotland, and Ireland. It is a common plant on the continent of Europe, and is said to occur in Africa and North America. Like most singular-looking plants, it has been used in medicine for a number of years, and is supposed to be a valuable remedy for all sorts of diseases.

O. vulgatus. Adder's Tongue is dry in the third degree. The leaves of Adder's Tongue stamped in a stone mortar and boiled in olive oil into the consumption of the juice; until the herba be dry and parched, and then strained, will yield a most excellent green oil or rather a balsame for green wounds comparable to oil of St.-John's-wort, if it do not far surpass it by many degrees, whose beauty is such that very many artists have thought the same to be mixed with verdigris.' Lightfoot says that the common people in Scotland make great use of the leaves, and use it as a vulnerary. It is also used in the same way in many parts of England.

(From Newman, Brit. Farns; Babington, Manual of British Botany.)

OPHYXYLON (from \( \text{ophy} \), a serpent, and \( \text{xylos} \), wood, because it has a twisted root and stems), a genus of plants belonging to the natural order Apocynaceae. It has a 5-cleft permanent calyx, a funneled-shaped corolla with a long tube, thickest in the middle, and a 5-cleft oblique limb. In India there are subspecies in the middle and the trochilidinds the tube. The ovary is double, each lobe with one ovule, a filiform enclosed style and a capitate stigma. The drupes are baccate, black, about the size of a pea, twin, or solitary by abortion, each containing a one-seeded wrinkled nut.

O. serpentiformis, Serpentine Snake-wood, is native of the West Indies. In rich soil it becomes a climbing plant, but in poor soil it is a small erect shrub. The leaves are in threes or fives; they are short-stalked, oblong, pointed, wavy, and smooth. The peduncles are long, smooth, round, sometimes nearly erect, sometimes drooping. The pedicels and calyces are of a bright red colour, and the calyx of the root of this plant is supposed to be used by the Telenga physicians as a remedy in many diseases. It is given inwardly as a febrifuge and after the bite of poisonous animals. The juice is also expressed and drunk, or the eye to the same purpose, and it is likewise given to promote delivery in tedious cases of labour. This plant is of easy culture and beautiful appearance. A mixture of loam, peat and sand is the best soil, and cuttings and readily strike and show a glass in heat.

(Don, Gardner's Dictionary. - Lindley, Flora Medica; Burnett, Outlines of Botany.)

OPHYRYS, a genus of plants belonging to the natural order Orchideae. It has a patent perianth, a variously lobed lip without a spur. The glands of the stalks of the pollen masses each in a distinct pouch.

O. opfera, Bee Orchis, has a tupid 3-lobed lip, the two lower lobes prominent and with a hairy base, the tube intermedium reflexed, truncate, terminal, acut, elongated and reflexed; the anthers with a hooked point, the petals oblong, bluish, downy. It is about a foot high, and has large, few, and rather distant flowers. The sepals are whitish tinged with purple. The lip is velvety, brown, variegated with yellow. It is one of the handsomest species of orchidaceous plants, native of Great Britain, and grows on chalky calcareous soils.

O. arachnites, late Spider Orchis, is distinguished by a terminal, infixed, flat, rather heart-shaped appendage, and delitd downy petals. The sepals are pink, the lip dark purple variegated, with a yellow disc, the appressed, the green, never reflexed. It is found on chalk downs near Folkestone and Sittingbourne in Kent.

O. transeus, Spider Orchis, has 5 oblate lobes, the middle lobe large, arcuate, with a erect appendage, the petals linear and puberulous. This species is smaller than the preceding, and with fewer flowers. The petals and sepals are green and quite glabrous. The lip is of a dark brown colour, hairy, and covered with pale or yellowish lines. It is found in chalky places in Kent and Sussex.

O. mucroneata, Fly Orchis, has an oblong trid or lip with a large pale spot in the centre, the middle lobe is elongated, dilated, the anthers short and obtuse, and the petals filiform. It is a slender plant and grows about a foot high. The petals are very narrow, and of a purple colour, the sepals green, and the lip of a purplish brown colour, the spot in the centre of the lip is a bluish tint. It is found in damp calcareous thickets and pastures in Great Britain.

(From Babington, Manual of British Botany.)

OPORINIA, a genus of plants belonging to the natural order Compositae. It has a capitulum, the head of the flower, the exterior scales much smaller in several rows, a punctured receptacle, attenuated uniform fruit; the pappus of all the fruit in one row, feathery, dilated at the base.

O. antennulata, the medicinal leaves, linear, lanceolate, toothed, or pinnatifid, nearly glabrous; stalk branching, scaly, and thickened upwards, the involucre glabrous or hairy. This is the Aptenia antiquata of Smth and the Lactuca antiquata of Koch. It is a native of Great Britain in meadows and pastures and on lofty mountains.

(From Babington, Manual of British Botany.)
OPHANAX, a genus of plants belonging to the natural order Umbellifere; it has an oblong calyx, roundish entire petals rolled inwards, with a rather scaly lobe; compressed seeds, and a diploate letter, which with unequally cuneate segments, crested and obtuse. The umbels are compound; the involucres both universal and partial, and the flowers yellow.

The native of the south of Europe and Asia Minor, on dry hills, margins of fields, and thickets. It is a plant six or seven feet high, of a dull yellowish colour, and resembling a parsnip. The stem is strongly furrowed; the leaves from one to two feet long, or even, flat, elliptic, with ovate cordate leaflets, which are usually obsolete at the base, often confluent, and surrounded by a curtiligineous cordate border. The calyx is inconstant, the styles rather short and hairy. All this plant is a native of Europe, the resinous gum which exudes from the stalk or root when wounded is brought from the Levant and East Indies in roundish drops of a reddish yellow colour, with specks of white. It is supposed to be an emmenagogue, but it is seldom used; it is similar in its effects to asafoetida. This is a plant of easy culture, and may be propagated either by seeds or dividing at the root.

(Don's Gardener's Dictionary; Lindley's Florae Medic.)

OPTOMETR (from the Greek words οπτική, to see, and μετρώ, a measure) is an instrument devised for the purpose of ascertaining with precision the refractive powers of individual eyes at which moment they are distinctly seen. The idea originated with Scheiner; but such an instrument was constructed by Dr. Porterfield for the purposes just mentioned, and was afterwards improved by Dr. Young, who named it the Young's Optometer.

Dr. Porterfield's contrivance consisted of a convex glass lens affixed by its frame to a slip of wood about two feet long: a pencil of light, diverging from a radiant point in the axis of the lens, was suffered to fall on a plate of metal in which were two small perforations; and the rays which passed through these, after being refracted in the lens, were received on a screen, where they formed in general two bright spots, but in certain positions of the lens and screen the spots united and coalesced as to form but one image. The distance of the single image from the lens, being measured by a scale of inches, constitutes the focal length of the lens for rays diverging from the radiant point. Dr. Porterfield used the instrument to determine the distance at which distinct vision of a small object takes place in the eye; the latter being substituted for the screen, to receive the rays coming from the object through the two perforations.

The instrument constructed by Dr. Young consisted of a slip of ivory, unpolished, or of wood covered with white paper, about eight inches long and half an inch broad, on which a black line, of its length, was divided into a number of well-defined black lines. At one extremity of the slip was fixed a plate of ivory, or a piece of card, nearly perpendicular to its length, and this was perforated either with a single eye or a pair of eyes; the distance of this from the distal end varying from 4th to 8th of an inch, but not exceeding the diameter of the pupil of the eye.

On applying the eye to a single aperture, and looking in the direction of the line drawn on the instrument, the line appears to have a certain breadth, and to be ill defined, at the nearest extremity: the breadth gradually diminishes at points successively more remote till it becomes a minimum, when the line becomes distinctly seen; but the point of its commencement increases in breadth, becoming again ill defined. On applying the eye to a double aperture, the line appears to be double, the parts seeming to cross one another at a very acute angle; and the intersection is at the place where a single line would have had the minimum breadth; beyond this intersection the two lines appear to diverge from one another, and become indistinct.

The point of intersection is at that distance where the minute object being placed, its image would be distinctly seen by the eye at the aperture, and its distance from the eye may be immediately found by means of a scale of inches on the instrument, a sliding index being, at the time of making an observation, placed on the horizontal line through the point of intersection.

This distance affords, evidently, a measure of the refractive power of the observer's eye; since rays of light diverging from a small object at that distance are, by the lenses of the eye, brought to a focus on the retina, and those rays which fall on the iris and pupil of the eye, as to form there a single and well defined image. If the object were brought either nearer to or removed farther from the eye, the rays, after passing through the two apertures, would form two images, both of which would appear to be less perfectly defined than the single image.

It being assumed that a person whose sight is perfect sees a small object 8 inches from his eye, Dr. Young obtained by computation a series of numbers which he placed on the scale of the optometer, at such distances from the plate containing the aperture, that a spectator having one of them fixed for his eye (or use one which one of the persons who are advanced in life, has distinct vision of small objects only when they are at greater distances than 8 inches) on looking through the slits and observing the place where the two images of the same object met, he would ascertain, at once, by the number at the place, the focal length of a convex lens which would enable him to see distinctly at 8 inches. He also computed a series of numbers which he placed on the scale at distances 1, 2, 3, and 4 inches from the small eye (or any one which has distinct vision of objects at less than that distance from it, on observing the place at which the lines appeared to intersect one another, might ascertain the virtual focus of a concave lens which would enable him to see distinctly at 8 inches. The optometer thus became a means of enabling persons to make choice of the proper lenses for spectacles which would correct the imperfections of their own natural vision.

But the scale of Dr. Young's optometer being, for convenience, only 8 inches long, and the inferior limit of distinct vision is a presbyopic eye being beyond that distance, Dr. Orsagna, another great optician, who has developed the subject to a wonderful extent, has applied his mind to the subject, by which the point of distinct vision for such an eye was reduced within 8 inches from it: the numbers on his scale were therefore computed for the instrument when furnished with a more refined eye.

Dr. Young used the optometer for the purpose of determining the refractive powers of the eye, not only in its usual state, but also when, in cases of cataract, the crystalline lens had been displaced or extruded, and when the effect of the corneal cornes had been rendered null by immersing the anterior part of the eye in water, which was contained in a cell of a proper form, and having a plane glass in front. By such means he endeavoured to ascertain in what manner the eye accommodates itself to distinct vision for objects at different distances from it; and his conclusion is that the faculty depends entirely (Lectures on Natural Philosophy, vol. ii. pp. 572-603) upon changes of figure which take place in the crystalline lens.

ORCAM, or L'ARCAGNULO, is the name by which Andrea di Cione, a celebrated old Florentine artist, is generally known; he is by HamoDram, which appears to be his proper name. Vasari calls him Orsagna. He was painter, sculptor, and architect; was born at Florence in 1520, according to Vasari, or according to another account in 1524. He was of Florentine extraction. He was an ardent disciple of Donato di di Field, and his works are arranged in his Sanzaio Santo di Pisa, where the Triumph of Death and the Last Judgment were by Andrea, and the Hell by Andrea; the last Judgment and the Hell are engraved by Lasinio in a single plate in his 'Futurismo del Campo Santo di Pisa.' Orsagna repeated them in Santa Croce at Florence; he had painted previously in the Strozzi chapel in Santa Maria Novella, a picture of Hell from Dante's Inferno, in which he introduced the portraits of several of his enemies. As an architect, he built the elegant Loggia de' Lanzi in the Plaza Granducia at Florence, which is still in perfect condition; and its sculptures are engraved by Lasinio in his 'Piazza de Granducia di Firenze, con i suoi Monumenti,' Florence, 1830. He built also the church of the monastery of Or San Michele, and designed the celebrated tabernacle of the virgin of the church of Santa Maria Novella. It is a high Gothic pyramidal altar to the Virgin, free on all sides, in black and white marble, and is richly ornamented with figures and other sculptures. The following words are inscribed on the base: 'Andrea Orcagna fecit super duas mennas oratorium architecti exhibuit hojas, MCCCLXX.' It is generally attributed to the school of di Cione, Firenze,' after a drawing by Andrea himself. Orcagna generally signed himself painter upon his sculptures, and sculptor upon his pictures; on his pictures he wrote 'Ferr Antonio di di Cione, Pietre.' He was also a poet. Vasari mentions some sonnets which he addressed to Burchiello; and in the works of Burchiello, published in London in 1767, there is a sonnet
addressed to Orsagna. He died at Florence according to Vasari in 1389, but according to Manni in 1375. He was a man of great taste in architecture, and has the credit of having been the first to adopt the principle of the semicircular arch in preference to the pointed; but to this merit, if one, he is not entitled, though his elegant 'Loggia de' Lanzi' may have contributed greatly towards the subsequent popularity of the arch. Among his other works, besides the semicircular arch, were the Lopo, and other circular arches, used the semicircular arch. Those, says Lanzi, who are fond of minute detail in minute things, may consult Baldinucci, Bottari, and Manni concerning Andrea. Rumbach, however, was the first to show in real name, of which Orsagna is a contraction, Lo Archangello Lo' rachiongl' orchangno. In painting, Orsagna did not go beyond Giotto; in sculpture he was worthy of notice. Of his writings, which is given by Vasari in the first edition only of his work, he was chiefly excellent as a sculptor, or rather statuary:—

His descends from the noble and princely among the Tuscan nobility, being understood to be his own. (Vasari, Vite de' Pitori, &c., and the Notices to his born's German translation of Vasari; Rumbach, Italianische Forschungen.)

ORDER IN COUNCIL. This expression is chiefly known by its connection with the West or Casersean orders of the great British government in 1807 and 1809, in retaliation of the Berlin and Milan decrees of Napoleon, by which Great Britain and her colonies were declared in a state of blockade. The measure was not very popular, not so much in France and its dependencies, but all who, either voluntarily or by compulsion, gave obedience to the decrees. A full account of the matter will be found under the head Blockades. There has been much dispute as to the legality of these orders. The law of nations has acknowledged the blockade as a legitimate form of commerce even of neutral or friendly powers, when the object is to punish the state so blockaded, and the belligerent power has a force on the spot sufficient to make the blockade actual and physical. But where a belligerent power goes beyond this, and declares some place at which it has no armed force under a state of blockade, it simply issues an edict against the freedom of commerce, authorizes its cruisers to seize vessels which are not impeding any warlike operations, and covertly declares hostilities against the states affected by the fictitious blockade. The law of nations has never countenanced such a license, and it came to be a question whether these orders in council, being thus not of an executive but of a legislative character, were legal, the Privy Council not having any legislative authority on the subject. In this matter it may be considered by act of parliament. In favour of the orders, it was maintained that they were merely part of the execution of the royal prerogative of declaring and conducting war, and that the order, or rather the act, by which individuals undoubtedly suffered, as individuals always must when warlike operations are conducted on a large scale. A analogy was taken from the exercise of the crown's prerogative during war, in prohibiting the supplying of the enemy with commodities contraband of war—an interference with the freedom of commerce justified by the necessity of the case. But these arguments did not satisfy the country generally that the measure, if it was a right one, should not have been accomplished by Act of Parliament instead of Order in Council.

It is difficult to draw the line between what may and what may not be accomplished by Order in Council. There have been various occasions on which, in cases of emergency, orders in council have been issued contrary to law, and those who have been concerned in passing, promulgating, or enforcing them have trusted to legislative protection, and taken on themselves the personal responsibility of the proceeding. In the year 1706, when there was a deficient harvest and the prospect of famine, an order in council was issued prohibiting the exportation from the British from the British. In the immediate ensuing parliament the act 7 Geo. III. c. 7 was passed for indemnifying all persons who had advised the order or acted under it, and for giving compensation to all persons on whose land it was executed. The order was referred to the order declared, which order could not be justified by law, but was too much for the service of the public, and so necessary for the safety and preservation of his majesty's subjects, that it ought to be justified by act of parliament. All orders restricting trade—unless when they are within the justification of the national war policy—and all orders counteracting the objects of the act of 1706, would require an act of indemnity. There are some matters affecting trade and the revenue, as to which orders in council are specially authorized by act of parliament. Thus in the Customs' Duties Acts, the national revenue is paid by the subjects of a state having a treaty of reciprocity with Britain, it is enacted that the treaty of reciprocity, and consequently the right to import at the lower duties, shall be declared by order in council. By the International Copyright Act, 1 & 2 Vict. c. 55, the countries which, by their conceding a term of copyright to works published in Britain are to enjoy a similar privilege here, may be declared by order in council.

OREGON QUESTION. The country known by the name of Oregon is bounded on the south by the parallel of 42° N. latitude, being the northern boundary of Mexico. On the north this territory is bounded by the parallel of latitude 54° 40', or, more strictly, this is the northernmost point on the coast, for in this latitude the irregularly shaped boundary of the Russian possessions in America terminates. On the east of it are the Rocky Mountains, and on the west the Pacific Ocean. It occupies a space of about thirteen degrees of latitude and fifteen degrees of longitude. Besides the Rocky Mountains, there are two other ranges, one called the Far West, or Cascades, and the other the Blue Mountains, dividing the country into three divisions, which are distinguished by peculiarities of soil and climate. The country between the Rocky and the Blue Mountains is almost uninhabitable by those who are not mounted on horseback. The land is not very far from the Pacific Ocean, is of small extent, and is not very valuable from a commercial point of view. The valley of the river Willamette, a tributary of the Columbia, is the most fertile district, is about 150 miles long and 60 broad. Wheat produces here about 20 to 30 bushels an acre. The winter is wet and stormy.

The territory north of the Columbia river and south of the parallel of N. latitude 49°, is that which is in dispute between the government of Great Britain and the United States. It is bounded on the east and the south by the Columbia river, on the north-west by the Straits of Juan de Fuca, on the west by the Pacific Ocean, and is roughly estimated to be a little larger than the state of New York. In the eastern half of this 'disputed territory' is described as 'a worthless desert,' the other half has a very large proportion of bad land. President Polk has claimed for the United States the territory north of 49° north latitude, as well as south of 49° to latitude 42°. Between Fraser's river, or latitude 49° and 54° 40', Captain Wilkes states, that nowhere on the coast could a settlement be formed that could supply its own wants. The claims of Great Britain and of the United States are both founded on an alleged title derivable from discovery, settlement, and treaty. Some writers have added to these elements of title, what they call 'contiguity,' but this is of no importance in the dispute.

I. The discoveries along the coast have been as follows:—

[The 57° 58' is an alteration of a translator; the original account is 57°, in words, not figures.]

| Vascoño | | 1596 | 49° |
| D'Agricol | | 1596 | 47° |
| Pelle | | 1774 | 55° |
| Heceta | | 1777 | 53° 36' |

[Inferred the existence of the Columbia from the general appearance of the embouchure or bay, and named it San Francisco].

| De la Bodega | | Spanish | 1775 | 58° |

[These last three voyages were kept secret by the Spanish Government].
Navigator’s Name. | Flag | Date | Latitude reached.  
---|---|---|---
Cook | English | 1778 | 44° to beyond 60°.  
[Early maps scarcely began Cook.]  
Commercial Expedition | Russian | 1780 | 60°.  
[Planned from information obtained from King, Cook’s successor. It started from the north, and proceeded no farther than the Arctic Circle.]

Various commercial enterprises, chiefly English, then took place, which ended in the seizure of English vessels by the Spanish Government in 1789. In 1800, the well-known names of Dixon, Portlock, Duncan, Colnett, Barclay, Douglas, and Mears; the last of whom may fairly stand Cook and Vancouver as discoverers, in the immediate region north of the Columbia.

Vancouver | English | 1792 | Surveyed the Coast.  
[Informed the existence of the Columbia from the river-colored water.]

Gray | American merchant | 1792 | Entered the Columbia.  
Baker | English merchant | 1792 | Entered the Columbia.  
[Broughton found Baker there, which shows that he had also been there in the earlier part of the year.]

Broughton, Vancouver’s Lieutenant, surveyed the Columbia for upwards of 100 miles above the estuary, and took possession, with the consent of the Indians.

The following are romances.

Lorenzo Maldonado | Spanish | 1588
Juan de Fuca | Spanish | 1592 | Professed to have discovered the north-west passage by sailing through the continent of North America.

Fonte, or De Fuenteras | Spanish | 1640 | 77°.  
[The last of the Spanish voyages—was published in 1708, in London, in ‘The Monthly Miscellany, or Memoirs of the Curious.’ Neither Fuenteras nor Fuca was ever noticed by Spanish writers. Fuca invented his story with a view of getting employed by Elizabeth; Fuenteras never existed.]

Hakluyt, in his ‘Collection of Voyages,’ published in 1589, states that Drake merely reached the lat. 40°, but his account is interpolated in the volume which contains it, and he appears to have intended to suppress it. In the edition of 1600 Hakluyt places the northern point of Drake’s voyage in latitude 43°.

The authorities for the higher latitude are: 1. ‘The World Encompassed,’ printed in 1578; and 2. Hakluyt’s ‘Superintendence of Francis Drake, a nephew of the admiral, which states that the coast ‘was searched diligently even unto 45°.’ 2ndly, Fletcher, who accompanied Drake, and whose MS. is in the British Museum. 3rdly, the celebrated navigator John Davis, in ‘The World’s Hydrographical Discovery,’ printed in 1585, says, that Sir F. Drake ‘coasted all the western shores of America until he came in the septentrional latitude of forty-eight degrees, being on the coast of Newfound land.’ An authority which ought to decide the question of the limit of Drake’s discoveries. 4thly, Admiral Sir W. Monson, who had served under Drake, and who says that Davis had never seen so high a latitude. In the account of the Spanish expedition under Galizano and Valdes, published by the order of the King of Spain, at Madrid, in 1802, is this passage—‘The true glory which the English navigator (Drake) may claim for himself is, having discovered the portion of coast comprehended between the parallels of 43° and 48°, to which consequently the name of New Albion ought to be limited, without interfering with the discoveries of preceding navigators. The discovery of the coast was, therefore, made by the British. But even if Drake had not discovered it still, according to the principles laid down by jurists, the exploration of Cook would be treated as conferring a title by discovery, since the voyages of Peres, Heceta, and Bodega were not made known until 1802. (Wolf, ‘Institutes du Droit des Gens,’ § 213; Vattel, book I. i. xvii. § 307.) The discovery must be made before the occupation is against it, or that it was a mere passing act, or that occupation not being intended, the territory was abandoned. Publicity is essential to enable foreign nations to recognize and respect the title founded.

Such was the condition of the title by more discovery when the Spanish officer, Captain Martines, in May, 1789, seized the British vessels the ‘Iphigenia,’ ‘North-West America,’ and in July, the ‘Argonaut,’ Captain Mathews, and the ‘Success Royal.’ A correspondence ensued between the governments of Great Britain and Spain, which occasioned a message from the king to both Houses of Parliament, delivered May 25, 1790, stating that ‘no satisfaction was made or offered for the acts of seizure, and that a direct claim was asserted by the court of Spain to the exclusive rights of sovereignty, navigation, and commerce in the territories, coasts, and seas in that part of the world.’ The claim of sovereignty made by the British Government was objected to, and Mr. Pitt stated that it was indefensible in its extent, and had originated in no treaty nor formal establishment of a colony, nor rested on any one of those grounds on which claims of sovereignty, navigation, and commerce usually rested.

This dispute was terminated by the convention of 1819. It is the third article of which declared that ‘the respective subjects of the contracting parties should not be molested in navigating or carrying on their fisheries in the Pacific Ocean or in the South Seas, or in landing on the coasts of those seas in places not already occupied, for the purpose of carrying on their commerce with the natives of the country, or of making settlements there.’

Great Britain then renounced its title to exclusive possession, founded on mere discovery—and any similar claim on the part of Spain was abandoned. The Convention was condemned by the opposition in parliament, the chief speakers asserting that Great Britain ought to have excluded Spain, and not to have conceded to it the right to settle on the coast. When it was pointed out where the fisheries could be, Pitt replied that he should esteem the government highly culpable if it neglected to ascertain by actual survey.

Captain Vancouver was sent by the British government to take possession of Nootka Sound, and to ascertain among other things how far to the north Spanish settlements had been established. He sailed from Deptford, January 6, 1791. Nootka Sound was delivered to him, but having a discussion on the extent of his instructions with the Spanish officers, Quadra, Lieut. Mudge was sent to England for further orders. Ultimately, in March, 1795, Nootka was delivered up to Lieut. Pierre of the marines.

It was while Vancouver was on this voyage that he received information that in May, 1792, Captain Gray, of the ship Columbia, from Boston, had entered the estuary of the river now known by the name of this ship. Vancouver had on the 27th of April observed the river-colored water of the river, but he did not attempt to enter the river in consequence of being directed by his instructions not to pursue any other inlet or river than should be navigable by vessels of a burden safely to navigate the Pacific. Shortly afterwards Lieut. Broughton in the Chatham, the consort of Vancouver’s vessel, entered the estuary, and found there the ‘Jenny’ of Bristol, Captain Baker, who had been there before in the early part of the year. Lieut. B explored the estuary, discovered where the river entered it, which Gray had not done, and ascended the river above 100 miles—taking possession ‘in the name of his sovereign, Gray, it must be observed, was a more private order, which had never been communicated to him, and which had been previously discovered, and his own government never noticed his proceedings until 1814. But if he had had a commission, the discovery of the entrance of the Columbia, and the attribution of this geographical discovery, without conferring no rights, for rivers follow the title to the coast, and their discovery does not affect or impair such a title.

After Nootka Sound was delivered up in 1796, the Spaniards never made any settlement north of Cape Mendocino. They abandoned the country, and left the British to perfect their title by discovery, through occupation and settlement. The subsequent expeditions to Oregon were as follow:

The expedition of Mackenzie was the first made by civilized men west of the Rocky Mountains.

The posts and settlements made by Thompson were the first established by civilized men west of the Rocky Mountains, and Thompson and his followers were the first white persons who navigated the northern branch of the Columbia or traversed any part of the country drained by this branch of the river.

Astor’s Pacific Fur Company consisted of Mr. Astor himself, six British subjects, and three citizens of the United States. Before those who were British subjects started, they asked for and received an assurance from the British minister at Washington—that in case of a war between the United States and Great Britain, they would be respected as British subjects and merchants.” The expedition received no sanction or support from the government of the United States. In 1813, the persons resident on the Columbia, having full power to deal with, sold their establishment to the North-West Company. Subsequently in the same year, Captain Black, R.N., in the Raccoon, took possession of Astoria in the name of his Britannic Majesty. Astoria was the winter headquarters of the Columbia river, under an article of the Treaty of Ghent, made in December 1814, as a post captured during the war. This was not the fact; but in 1816 possession was formally delivered up, the British government having previously stated that the post had not been captured, and that the territory had early been taken possession of in his majesty’s name (as it had been by Broughton); but that the question of title should be discussed in the negotiation on limits and other matters, which was soon to be commenced.” (Greenhow, 307, 310, 312.)

On the delivery of this post the United States for the first time exercised any act of sovereignty in Oregon. It was put into possession, but not relieved from proving its title, for its possession was derived from Great Britain.

In October, 1818, a treaty between Great Britain and the United States declared that the country should be open to the navigation of the American government, and that claims of either power or to the claims of any other power.

In February, 1819, the United States made the Florida Treaty with Spain, which declared part of the west boundary of the United States to be the watershed between the rivers that flow into the sea, both parties ceding to each other, and respectively renouncing, all claims on either side of this line. The Americans pretend that this treaty conveys a title to the coast north of 42°, though Spain never completed or obtained a title by occupation.

In August, 1827, a treaty between Great Britain and the United States extended indefinitely the provisions of the treaty of 1818, until determined by notice of a year, and it was not to impair the claims of either party. This treaty is still in force, but the Congress of the United States in April 1846, authorized the notice to terminate it to be given.

1. The government of the United States contend, notwithstanding their treaty of 1818, that Spain alone was entitled to Oregon until 1819. In reply it is said that the British title was acknowledged by the Convention of the Escorial—that Spain never made a settlement in the territory, but totally abandoned it—that Spain had no title either by discovery or occupation—that all the rights or claims which it had were derivable from the treaty of 1790—and that official Spanish writers admit the British title by discovery, 4th July, 1811. 2. It is contended that Gray discovered the Columbia, and that this is of itself a sufficient title to Oregon. In reply it is said that rivers follow the title to the coast—if the coast was discovered, the rivers follow the title to it; that Gray was not acting under a public commission, and could not, as a private person, extend the territory of the United States—

that his discovery was never noticed by his own government for upwards of twenty years—and that in the negotiation with Spain in 1819 it was not set forth.

3. The settlement of Astoria is called a national settlement. In reply it is said that the only sanction the adventurers received from the British government, that it was a mere private speculation by a party of men, the majority of whom were British subjects, who had asked for British protection—that the application to the United States government to sanction the enterprise was disapproved, and could not be planted beyond the limits of the United States without the authority of an Act of Congress.

The British title depends on original discoveries made by Drake, Cook, and Vancouver, whose acts were sanctioned and approved by of their sovereigns, and notified to the world—on the acknowledgment of the title made by Spain in 1790—the restoration of Nootka in 1795, as evidence of an acknowledgment of territorial rights—on the possession taken by British officers, which by our law, when done with the sanction of the sovereign, is alone sufficient to make a country part of the dominions of the crown—on the numerous settlements and posts which our government has allowed the North-West Company and the Hudson’s Bay Company to establish—on the recognition of the claims of the British government made by the United States in 1813 on the sovereignty which those acts of recognition proclaimed, and which was recognized by the United States before its treaty with Spain in 1819, as well as subsequently in the treaty of 1818.

Great Britain does not assert claims beyond the terms of the treaty of 1790. The United States some time since claimed the whole territory, without ever having obtained any legal authority over it, or control of it, and they now allege the extent of this bare claim as evidence of having a better title.

In the course of the early negotiations the United States government offered the boundary of 49° to the sea and the navigation of the Columbia river. Great Britain maintained that the line should run along 49° to the Columbia river, then along the Columbia river to the sea, agreeing not to erect any fort at the mouth of the river. Subsequently it agreed part of the line to be 51°, and 52°. In the last negotiation carried on by Mr. Pakenham and Mr. Buchanan, the United States offered a boundary along the parallel 49°, withdrawing the former proposal respecting the Columbia river; and the correspondence closed with an assertion of an exclusive right to the entire west coast from 42° to 54° 40’, thus denying every claim made by Great Britain and hitherto recognised by the government of the United States. There are signs that this violent policy and disregard of the admissions made in former negotiations will not be supported by the people of America, and it is to be hoped that they will not be indifferent to what is just and reasonable. The British government offered to refer the question to arbitration, and the last offer was very remarkable for proposing that the arbiters should be civilians, in order to avoid the apprehension which republicans might have of a decision by a tribunal constituted by foreign nations. They refused, and the last refusals was accompanied with most objectionable reasons.

OREODAPHNE, Mountain Laurel (from spinos, mountainous, and daphne, a laurel), a genus of plants belonging to the natural order Lauraceæ. It is hermaphrodite, dioecious, or polygamous, with 6-parted nearly equal calyx, the limb eventually disappearing. It has 9 stamens, oblong anthers, with narrow filaments, 4-celled, the inner looking outwards. The fruit is sucrose, in less intensity, or less intense, in the cup formed of the altered tube of the calyx. The flowers are panicked or racemose, axillary, and occasionally umbellate. O. opifera is native of the woods of Paris and the Rio Negro. It has less sugar. It is chiefly used in Brazil as a remedy in pains and contractions of the limbs. O. cupularis is a very large tree, with a strong-scented...
wood; it has ovate elliptical leaves, borne at both ends, sometimes blunt at the apex, ending in a channelled stalk, obliquely netted, smooth; the axils of the costal veins without pores. The flowers are in clustered few-flowered rough hoary racemes below the axillary and terminal bud. The calyx of the fruit is hirsute. This species is rare. *This is the Isle of France, where it grows, and also in Bourbon and Madagascar.*

ORGANIC CHEMISTRY. [Timper, Animal, P.C.S.]*

ORGANON. *The article Organon in the P.C. contains a general view of the nature and object of logical science; and the article Stilling contains all that is necessary on that subject.* They will both be highly needed to complete what has been already given.

The *Elementa Logicae Aristotelicae,* by Professor Trendelenburg, Berlin, 1842, 2nd edition, consists of passages selected from the works of Aristotle, which passages may be considered as containing the elements of the science. These passages are so arranged as to present a kind of outline of the whole logical system of Aristotle. They are intended for the use of the higher classes in gymnasia, and as a preparation for philosophical studies.

The following article is simply a translation of these extracts, which are retained in the order given to them by Trendelenburg. In the places where references to the original works in Aristotle have also been retained. The original terms of Aristotle are also given in brackets the first time that each is mentioned.

In the preface to another useful work (Beiirirtungen zu den Aristoteleischen Rhetorischen Werken, Berlin, 1842, by the same author), he has more fully explained his views in making these extracts from Aristotle, and the following remarks are his: At the time of the Reformation Luther saw clearly the advantage of logical instruction in the higher schools, and he viewed it correctly as the completion of the grammatical instruction. The circle of studies in modern times has been wonderfully enlarged, and it has been found necessary to extend the school instruction to meet the wants of the present age. But the great variety of subjects with which our present systems of education occupy us, only render the more necessary to discipline the mind in such a manner that it shall see a unity in all that is presented to it, and not be bewildered by the variety of objects whose connexion escapes us, when they are contemplated separately. Such a discipline is furnished by a good course of elementary instruction in logic. For this purpose the author has adopted the genuine words of Aristotle, in which the philosopher has laid down his elementary logical principles. The logic of Aristotle is not antiquated, though it is both misunderstood by some and misused by others who do not understand it. It is not the formal logic of Kant, which would confine us to the forms of thought without any reference to the object into which the thought penetrates. Such a limitation of the subject matter of the science of Aristotle, as the author opposes to its real character. *We have,* says Trendelenburg, *attempted to restore this real character,* and thus brought Aristotle nearer to the objective demands of modern times. He has endeavoured to make the logic as purely formal, viewed in a different light, and they who may consider their mode of viewing the subject to be better than his. Those who say that Aristotle has, in some matters, erroneously extended the province of logic to things beyond its limits, and has not always kept close to the real subject. appear to have conceived that he viewed it merely as formal, and sometimes transgressed the boundaries of the science which he recognised. This is however an erroneous view of Aristotle's system.

The advantage of studying these elementary principles in the words of Aristotle is, that in his writings the language of philosophy is formed into a scientific terminology, which is the basis of that which we now use. We cannot therefore lay a sure foundation for our logical and philosophical studies on any other basis than a full comprehension of the meaning of Aristotle's terms.

The author remarks that a learner of logic there meets with those fundamental notions (begriffe) in their simple nakedness, which lie hidden in all our knowledge and govern it. As these notions are hid or concealed in our knowledge, they appear to the pupil when they are presented in their naked form. It is therefore the business of the teacher to show to the pupil their real significance, to make him see their actual value in their application. Now the instruction in the German gymnasia, which are the highest in Germany and Ireland, is in the learned languages and in mathematicae; and accordingly the teachers in both those departments, if they are to make use of such a work as Trendelenburg's, must be able to apply logical principles to instruction in language and in mathematics. To facilitate this method of instruction is the object of the learned author in the Illustrationen (Erklärungen) to the Elementary Logic (Elementarlogik), which is said to be this is precisely the form in which he supposes that they ought to be presented to the pupil, but 'merely to render clear the fundamental notion of the logical relationship in the objects of scientific observation.'

The mode in which the author suggests that his two works should be used is probably the best; but they cannot be used at all in ordinary instruction, except under the guidance of a competent teacher. They will be useful to those who have a competent knowledge of the Greek and German languages, and possess some elementary notions of logic; and those who cannot read Greek with facility will probably find the following translation sufficiently exact to give them the meaning of Aristotle. A translation of such extracts is not easy, and it is possible that there may be some errors in it. A careful study of these extracts however will convince a student how meagre and unsatisfactory an exhibition of the elementary principles of logic even our best works on the subject contain.

Outline of Logic.

(1.) In things in which there is a falsehood and truth, there is a composition of ideas as though they were one. (De Anim. iii. 6.) For falsehood and truth are concerned with composition and separation. Accordingly nouns and verbs by themselves alone can make no assertion, as 'man' or 'white,' when nothing is added: for there is so far neither falsehood nor truth. (De Interpret.) Consequently he thinks truly who considers that which is separated to be separated, and that which is compounded to be compounded; but he thinks falsely whose thoughts have a different relation from that which the things have. (Metaph. i. 10.)

(2.) All speech (λόγος) is significant, but not all enunciative (διαφωνητικός). Speech is not truth or falsehood. But it is not in all; for example, prayer is speech, but neither true nor false. The enunciative alone belongs to the present inquiry. (De Interp. c. 4.)

(5.) Of things said with no condition, each signifies either substance (ὑπόσως) or quantity, or quality, or relation, or where (space), or when (time), or position, or possession, or acting, or being acted on. And substance (ὑπόσως) is, to give an example, such as 'man,' 'horse,' etc., quantity is, such as two cubits, three cubs: and quality, such as white, grammatical: and relation, such as double, half, greater: and where, such as in the Lyceum, in the agora: and when, such as 'yesterday,' 'to-morrow': and possession, such as he has sheep on, he is armed: and acting, such as he cuts, he burns: and being acted on (εἰς ὑπόσως), such as he is cut, he is burnt. (Categ. c. 4.)

(4.) Of things said with condition, each signifies, the same, or is the same, or is not the same, or is not unlike, or is contrary, secondly a negation. And affirmation (αἰτιουμένος) is an enunciation of something towards another thing; and negation (ἀφάσις) is the enunciation of something away from another thing. And the same, or is the same, is another name for the universal, and Callias to the particular. (De Interp. c. 7.) A Proposition (στάσις) then is speech either affirming or denying something about something. And this speech is either universal or particular or indefinite. I call that universal which belongs either to all or to none; I call that particular which belongs either to some one, or not to some one, or not to all; and I call that indefinite which either belongs to some one, or to none, or not to all. (De Interp. c. 5. 6. 9.)

(5.) Not-man is not a noun; for indeed there is no name to call it by; for it is neither affirmative speech nor a negation. But let it be called 'name or noun indefinitely,' because it can be said equally of anything, both of what is and what is not. Every affirmation and negation will consist either of a noun and a verb or of an indefinite noun and a verb. But without a verb there is neither affirmation nor negation. (De Interp. c. 2. 10.)

(6.) Of things some are universal and some particular. I call that universal which can be said of more things (than one): and I call that particular which cannot: thus, man belongs to the universal, and Callias to the particular. (De Interp. c. 7.) A Proposition (στάσις) then is speech either affirming or denying something about something. And this speech is either universal or particular or indefinite. (De Interp. c. 7.)
if a man know that the angles of every triangle are together equal to two right angles, he know in a way that the angles of an isosceles triangle also are together equal to two right angles potentially (δύναμις), even if he does not know that the isosceles triangle is a triangle. But he who knows this proposition potentially, as well as every triangle, and a single thing, and what is an object of sense; but of these things others can be predicated (for each of these persons is both man and animal); and some things are themselves predicated of other things, but of them there is no further predication by other things; and some are both themselves predicated of others, and others of them, for example, 'man' is predicated of 'Callias,' and 'animal' of 'man.' Accordingly there are some things which exist which cannot be predicated of anything is manifest. For of sensuous objects nearly every one is such that it can be predicated (ἐπιτρέπει) of nothing. (Anal. Pr. i. 27.)

The genera are predicated of the species, but not the converse, the species of the genera. (Categ. c. 5.)

(9.) It is impossible for the same thing at the same time to be and not to be possible, i.e. to be and not to be at the same time. This indeed of all principles is the most certain; for it is impossible for any one to conceive that the same thing is and is not. Wherefore all who demonstrate, cast down their demonstration (διά τὸ διάταγμα) to this ultimate notion. (Metaphys. iv. 3.)

Every thing which is true must agree with itself in every way: for with truth all which is true is in harmony, but with falsehood the truth is at soon variance. (Ethics. Nic. i. 8.)

(10.) And since it is possible for what belongs to be enunciated as not belonging, and what does not belong as belonging, and what does not belong as belonging, and with respect to other times than the present in like manner, it is possible to deny both that a man has affirmed, and to affirm what he has denied. So that it is manifest that to every affirmation a negation is opposed, and to every negation an affirmation; and let the contradiction (διαταγμα) be this, affirmations and negations opposed. And I call opposition (διαταγμα) the contradiction of the same thing about the same thing, but not ἐπιτρέπει: (Comp. Categ. c. 6; De Interp. c. 6.)

Contradiction is opposition (διαταγμα) in which there is no man in itself. And as parts of contradiction, there is on one side affirmation and on the other side denial, nor is there anything denying something from ἄνυδος something. (Anal. Pr. i. 2.)

In affirmation and negation always, whether it is a thing that exists and is not existent, the one will be false, and the other true: for of the two, the Socrates and that Socrates is not sick, when Socrates exists it is manifest that one of them is true and the other false, and if he does not exist in the same manner: for that he is sick, when he does not exist, is false, and that he is not sick is true.

Accordingly, as these things alone, which are opposed as affirmation and negation, it will be peculiar for one of them always to be true or false. (Categ. c. 10.)

(11.) Things included in the same genus which differ most from one another, are defined to be contrary (ἐναντίως). (Categ. c. 6.)

I therefore say that affirmation is opposed to negation in the way of contradiction, when the one signifies that a thing is universal and the other signifies that the same is not universal: as for example, every man is white—but not every man is man; no man is white—a certain man is white. And I say that the universal affirmation and negation are opposed as contraries: as for example, every man is white—no man is white; every man is just—no man is just. Therefore it is not possible for these to be true at the same time. (De Interp. c. 7.)

(13.) And I say that propositions opposed are in common expression (ἐκατ' ἄλλος) four—namely, all and none, all and some, some and none, and in truth some for some is opposed to not some merely in expression. And of these three propositions the universal, all and none, are contrary; for example, all knowledge is excellent, no knowledge is excellent; but the other propositions are opposed (as contraries). (Anal. Pr. ii. 15.)

(14.) And since every proposition is either of being or of necessarily being or of the possibility of being, and of these some are affirmative and some negative in every mode, and again of the affirmative there is universal and particular, and of the negative some are universal and some particular and some indefinite, of necessity the proposition which is universally negative can be converted (ἐπιτρέπει) in its terms (ἐπιτρέπει): for example, if no pleasure is a good thing, neither is any good thing pleasure; but the affirmative proposition must be converted, not indeed universally but particularly; thus if all pleasure is good, some good also is pleasure. And of particular propositions the affirmative proposition must be converted, not particularly, for if some pleasure is good, some good also is pleasure: but as to the negative, it is not of necessity, for, if 'man' does not belong to (cannot be predicated of) some animal, it does not follow that 'animal cannot be predicated of some man.' (Anal. Pr. i. 2.)

(15.) The things which are sought are equal in number to the things which we know. And we seek four things—the That, the Why, If it is, What it is. For when we seek whether this or that is, referring it to number, for example, whether the sun is eclipsed or not, we seek the That. And there is proof of this, for when we have found out That it is eclipsed we cease inquiring; and if from the beginning we know That it is eclipsed, we do not inquire whether it is. And when we know that it is, we inquire the Why: for example, that the sun is eclipsed, when the earth moves, we inquire why the sun is eclipsed or why the earth moves. These things accordingly we inquire after thus; but some things we inquire after in another manner, as for example, whether or not it is true. And so, unless it is simply mean if there is or is not, but not if he is white or not. And when we know that there is, we inquire what It is, for example, what is God or what is man. (Anal. Post. iii. 1.)

(16.) To know That a thing is and to know Why it is are different; and the knowledge of the Why refers to the first cause. The chiefest of knowledge is to contemplate the Why. (Anal. Pr. ii. 1.)

(17.) And we think that we know each thing simply when we think that we both know the cause by which the thing is, that it is its cause, and that it cannot be otherwise. (Anal. Post. i. 2.)

(18.) All instruction and all rational learning come from knowledge preceding. And this is manifest to them who contemplate all (sciences); for both those of the sciences which are mathematical by these means exist, and every one of the other arts. (Anal. Post. i. 1.)

(19.) And things are prior and better known in two ways: for it is not the same thing to be prior by nature and prior as something else. Let us regard as it seems to be the better known: for example, the sun is better known by us. And I call those things prior and more known as regards us which are nearer the sense, but I call simply prior and more known as regards us which are from the conception. And the farthest off are the least universal, and the nearest the particular. (Anal. Post. i. 2.)

(20.) We get certainty in all things either by syllogism (συλλογικῶς) or by induction (ἐπιτρέπει). (Anal. Pr. ii. 23.)

We learn either by induction or demonstration (ἐπιτρέπει) and demonstration proceeds from the general, but induction from the particular. (Anal. Post. i. 18.)

(21.) And syllogism is speech, in which when some things are laid down, something else different from what are laid down results by virtue of their being laid down; and by virtue of their being laid down: I mean that it is through them; and I mean by resulting through them, that there is no need of any external term for the necessity to be. (Anal. Pr. i. 1.)

(22.) And I call Term that into which the proposition is resolved, as the predicate and the thing of which it is predicated (subject). (Anal. Pr. i. 1.)

(23.) Whatever so affirmed of the predicate, will be affirmed of the subject. (Categ. c. 6.)

(24.) When three terms are so related to one another that the last is in the whole of the middle, and the middle is either in or not in the whole of the first, and there is there is a perfect syllogism of the extremes. And I call middle that which is both itself in another and in another, and which also by position becomes middle: And I call extremes both that which is in another, and in another the
is. For if A can be predicated of all B, and of all C, necessarily -A can be predicated of no C. And I call a figure (εὑρίσκω) of such description the first. (Analyt. Pr. i. 4.)

(25.) And when the same thing belongs to all of one thing and to none of another, or to all or none of each, such a figure I call the second, and which is predicated of both or none of the middle terms, which in the terms is placed without the extremes (ὅποια), but the first in position —And a syllogism will be possible both when the terms are universal and when they are not universal. When they are universal, if the middle term is a syllogism: of one, and in none of the other, if the negative be in one of the two terms: but otherwise the syllogism cannot be.

For let M be predicated of no part of N, but of all X. Since then the negative proposition can be converted, N will belong to no part of M: but M by the supposition was predicated of all X. Accordingly N will be no part of X: for this has been shown before. Again, if M shall belong to all N, but to no part of X, neither will N belong to any part of X: for if M belongs to no part of X, neither will X belong to any part of M: but M by the supposition belongs to all N. Therefore, if X will belong to no part of N: for this also has become the first figure. And since the negative proposition is convertible, neither N will belong to any part of X, so that there will be the same syllogism. An affirmative cannot be produced by a figure, but they are all negative, both the universal syllogisms and the particular syllogisms. (Analyt. i. 5.)

(26.) But if one thing belongs to the whole of the same thing as another has no part, or both to part of the whole or to no part, such a figure I call the third; and I call that the middle in it of which both the predications are made, and I call the extremes the predications:—And the middle is placed without the extremes, and last in position—And a syllogism will be possible both when the terms are universal and when not universal with reference to the middle. Accordingly if they are universal, when both P and R belong to all S, and Q belongs to some part of R, or is of necessity belongs to some part of R: for since the affirmative is convertible, S will belong to some part of R, since S belongs to all of S, and S belongs to some part of R: for the syllogism is produced by means of the first figure.

To form a syllogism universally by means of this figure is not possible, neither in the negative nor in the affirmative. (Analyt. Pr. i. 6.)

(27.) And it is manifest that every demonstration will be by means of three terms and not more. And since this is clear, it is manifest that it consists of two propositions and not more: for the three terms are two propositions. (Analyt. Pr. i. 36.)

(30.) It is necessary in all the figures that the middle be in both the propositions. If then the middle term both predicated and subject of predications, if it itself predicated, and anything is denied of it, it will be the first figure, but if it both predicates and is denied of something, it will be the middle figure: and if other things are predicated of it, or one thing of another, if it is predicated of it, it will be the last figure. (Analyt. Pr. i. 82.)

(28.) Moreover in all syllogisms one of the terms must be affirmative and it must be universal: for without the universal there will either be no syllogism, or it will not relate to the thing proposed, or the very thing to be proved will be assumed. For let it be proposed to prove that music is an honourable pleasure: if then any one should assume that pleasure is honourable without asking the 'all,' it will not be a syllogism: and if he should assume that some pleasure is excellent, if he means other pleasure, it has nothing to do with the subject proposed, and if he means the very pleasure itself, he assumes the very thing which is to be proved. (Analyt. Pr. i. 24.)

(30.) The science of what a thing is, it is possible to investigate by means of this figure alone (the first). For in the mind it is possible to separate the like things from the unlike (ὁμογένεια) what science is, requires the affirmative: and in the last figure there is a syllogism, but not a universal syllogism, and the question what a thing is, belongs to the universal. (Analyt. Pr. i. 25.)

(31.) All who attempt to syllogize from things less credible than the conclusion, manifestly do not syllogize rightly. (Top. i. 4.)

(32.) From what is true it is not possible to form a false conclusion, but from what is false it is possible to form a true conclusion; not however 'why' but 'that' the thing is. (Analyt. Pr. ii. 2.) Accordingly it is manifest that, if the conclusion be false, of necessity those things are false either wholly or partly. And particularly, the argumentation of the first mode is, when the conclusion is true, it is not matter of necessity for either anything or all to be true, but it is possible when none of the things in the syllogism are true, for the conclusion not to be true. And in the third mode, when the middle term is of one, and in none of the other, if the negative be in one of the two terms: but otherwise the syllogism cannot be.

And speech is called false in one manner, when it appears to be conclusive but is not conclusive which which is called intuitive syllogism (φυσικά καταλήγουσα). (Top. viii. 12.)

Contentious speech is the syllogizing from notions that appear to be common notions, but are not; or it is merely apparent reasoning not from premises. (Top. viii. 5.)

The equality of opposite arguments (ανθώρων) would appear to be productive of doubt. (Top. vi. 6.)

(34.) Induction (αναγκή) is the progress from the particular to the universal. And if someone is to be told the principle: and if a charioteer who is skilled is so, universally also the person who is skilled in each thing is the best. And induction is the more persuasive and more credible, and more intelligible to sense, and in value among the many: but the syllogism has more force and is more effective against opponents in argument. (Top. i. 12.)

(35.) Induction then and the syllogism from induction, is through one, or but is not the induction of the middle term; for example, if B is the middle term of A and C, by means of C to show that A may be predicated of B: for thus we make inductions. — But C must be considered as composed of all things individually: for induction is made through all. (Analyt. Pr. ii. 23.)

(36.) In a manner induction is opposed to syllogism; for the one (syllogism) by means of the middle term proves the first term to be predicated of the third, but the other (induction), by means of the third term, proves the first to be predicated of the middle term. Naturally then the syllogism through the middle term is prior and more familiar; but to the syllogism through induction is the clearer. (Analyt. Pr. ii. 28.)

(37.) Probable (εἰκός) and Sign (εἰρωτός) are not the same, but εἰρωτός is a proposition conformable to opinion for what for the most part men have been in the habit of approving: in a particular way or not produced, or to be or not to be, this is probable; for example, that men hate the envious, or like the wise. But the syllogism, when a proposition is given and when a sign to opinion: for if when anything is, the thing is, or when anything has happened, the thing happens before or after, this is a sign of the thing having happened or being. (Top. i. 6.)

Enthexmena then (ενθοσύνεια) is a syllogism from probables or signs. (Analyt. Pr. ii. 27.)

(38.) And an example is, when the first is shown to belong (εἰκός) to the middle through one the last. But it must be known that both the middle belongs to the third and the first to the like. For example, let A be bad, and B be to take up war against neighbours; and C, the Athenians, taking up war against the Thebans; and D, the Phocians, taking up war against the Phocians. If then we wish to show that to make war on the Thebans is a bad thing, we must assume that to make war on neighbours is bad. And the evidence of this is the opinion of the Athenians, because the man who makes war on the Thebans against the Phocians is bad. Since then to make war on neighbours is bad, and since the war against the Thebans is against neighbours, it is manifest that to war against the Thebans is good. According to this: if B belongs to C and to D (for both C and D are to take up war against neighbours), and that A belongs to D (for the war of the Thebans against the Phocians was not good); then that B belongs to C is shown through B.

And in the same manner also if through more like things,
(45.) The object of science and science differ from the object of opinion and opinion, in as much as science is universal and is of necessity, and the necessary can not be otherwise, but opinion is unsatisfied in the opinion. And (46.) Induction is not possible when there is no sensuous perception; for sensuous perception belongs to the particular. Nor yet through science; for science is impossible to have sensuous perception of, for it is neither any particular thing nor; for, if it were, it would not be universal; for we can not form that the sensuous and the essentia of it. Wherefore also if we were in the moon and saw the earth intercepting the light of the sun, we should not know the cause of the eclipse, for we should perceive that it is eclipsed now, but we should not know why at all, for there would be no sensuous perception of the universal. (Analyst. Post. i. 18, 31.)

(47.) And I call universal whatever belongs to all both of itself and in itself. It is manifest that whatever is universal of necessity belongs to the things. And the of itself and in itself are the same; for example, of itself a point belongs to a line insmuch as it is a line; and to a triangle, inasmuch as it is a triangle. But of itself the same, and of itself of the triangle (as to equals) is equal to right angles. And the universal then, when it can be demonstrated of any individual (of the class) and of no class prior to that, (Analyst. Post. i. 18, 31.)

(48.) To what thing anything of itself belongs, that thing it is its own cause (de.eo); and the universal is first, therefore the universal is the cause. (Analyst. Post. i. 24.)

(49.) Universally, of all things it is impossible for there to be demonstration; for it would proceed indefinitely, so that thus there would be no demonstration at all. (Metaph. iv. 4.) And it is not possible for the thought to go through the infinite. (Analyst. Post. i. 24.)

(50.) And those things are true and first which not other things, but through themselves receive asent; for it is not necessary in scientific first principles for the 'wherefore' to be inquired after, but each of the principles must itself of itself receive asent. (Top. i. 1.) And in two ways it is necessary first to know: for as to some things it is necessary first to admit that they are; but as to others it is necessary to understand what the thing spoken of is; and as to others again both; for example, in the proposition that either to affirm or deny every thing is true, we must assume the 'is'; and in the triangle, that it signifies this particular thing; and in the monad, both, what it means and that it is. (Analyst. Post. i. 1.)

(51.) But we assert that all science is not demonstrative, but that of the immediate (σωφρον) is incapable of demonstration. And that of the immediate is admitted of itself of itself, in so far as it is necessary to understand the principle things of the proposition comes, and the immediate at that time goes into the demonstration, it is manifest of necessity that the immediate are not capable of demonstration. And this then we so affirm, and that there is not only science, but also science of first principle (ὑπόδεικνυμαι) of science by which we know the terms (ἐνοχῇ). It is necessary not only to know first the things, either all or some, but also to know them more; for always through which each thing is, is more (in a higher degree); for example, that through which we love, is more love. So that if we know by the first things and believe, those things also we know and believe more, since by them we know also the things which come after. (Analyst. Post. i. 3, 2.)

(52.) And an immediate proposition (προτέρως) is a beginning (ὑποδεικνυμα) of demonstration, and an immediate proposition is that to which there is no prior proposition. (Analyst. Post. i. 2.)

(53.) And of the immediate syllogistic beginning I call that the Thesis which need not be demonstrated, and which it is not necessary that he who is going to learn anything should possess; but what he who is going to learn anything must necessarily possess, is an axiomatic (διαπρώτα). (Analyst. Post. i. 2.)

(54.) The first things will be definitions (ὅροις) incapable of demonstration. For definition is of what the thing is and of essence; and all definitions are hypothesis and to assume what a thing is, for example,
mathematical demonstrative case for granting what a unit is and what odd is, and other kinds of demonstration in like manner.

The definition is a certain notification (γνωματική) of essence. (Analyst Post. ii. 3.)

A science shows either what a thing is or what the name means. (Analyst Post. ii. 7.)

All who in any way by a name give an account of a thing, manifestly do not give the definition of the thing, since every definition is a notion (λόγος). (Trop. i. 5.)

What a triangle means, the geometer assumes; but that it is, he proves. (Analyst Post. ii. 7.)

(56.) And it is necessary to investigate, when considering things, whether they do not differ in the first place what they all have in common, then again with respect to other things what things they have which are of the same genus as the former, and are the same one another in species, but different from the first named. And when in these things it has been found what they all have in common, and in the other things in like manner, we must consider again if there is anything in common in these things which have been taken, until you come to one notion (λόγος): for this will be a definition of the thing. But if a man does not come to one notion, but to two or more, it is manifest that what they all have in common cannot be one but more than one for example, if we should inquire what magnanimity is, we must consider in the case of some magnanimous persons whom we know, what one thing they all have by which they are such. For magnanimity is magnanimity of Ajax, and of Achilles, and of Ajax, what one thing they have in common? Non-endurance of insult: for the first made war, and the second was enraged, and the third killed himself.

If notions of others, such as Lycurger or Socrates; if indifference in prosperity and adversity are the things that they have in common, these two things I take and consider what same things are contained in the absence of all feeling (άσκεσις) as to fortune, and non-endurance of insult. If they have nothing in common, there must be two species (τύποι) of magnanimity. (Analyst Post. ii. 13.)

(57.) Of the things indeed which are in the definition each one is a notion, but all will not extend further. For of necessity there must be this essence (ονήμα) of the thing: for example, there is number in every Three (τρίαδα), odd (ετεροτρία), and the prime in both ways, both as not to be measured by any number and not to be composed of numbers. This then is Three, number odd, and prime, and prime in this manner: for of each of these things some are in all odd numbers also, but the last is in Two also, but all are in none. (Analyst Post. ii. 13.)

(58.) And it is necessary, when a person is labouring at any whole thing, to divide the genus (γένος) into things indivisible in species, the first; for example, to divide number into even and odd. (Analyst Post. ii. 13.)

All genus is divided by differences which are opposed to one another in division, as a living animal by the difference of quadruped and bird and fish. (Trop. vi. 6.)

It should fall under no extension, if they be things opposed in which there is no middle, is not an assumption, for it is necessary that everything should be in one of them, if there should be a difference (διαφόρον) in it (the genus). (Analyst Post. ii. 13.)

It is requisite moreover to divide by privation (ερίσεως), and those cut into two parts divide by privation. And there is no difference in privation, so far as it is privation, for it is impossible that there should be species of a thing which does not exist; for example, of animals without feet or animals without wings, as there is in the case of winged animals and quadrupeds. (De Fertil. Anim. i. 3.)

(59.) Definition consists of genus and differences. (Trop. i. 5.)

It is requisite that he who defines well define through genus and differences, and these belong to those things which are in a certain way prior to the species (τύποι). And there are three ways in which the definition is not from prior things. The first is, if through what is opposed that which is opposed is defined; for example, if through evil, what is opposite to evil for the opposite is the nature. But to some the knowledge of each of them appears to be also the same, so that neither is one better known than the other. But it should not escape notice that some things perhaps it is not possible to perceive, or otherwise, for the doubles without the half, and all those things which of themselves are said in relation to anything (ἐκ τοῦτο): for in all such things to be is the same thing as to be related to something in some manner, so that it is impossible without the one to know the other; wherefore it is necessary in the notion (λόγος) of the one that the other also be included.

Another way is, if a man uses the very thing which is defined. But this escapes notice, when he has not used the name itself of the thing defined; for example, if he defined the sun to be a star which appears in the day time; for he who employs the word day employs the word sun. And it is required in order that such things may be defined, to exchange the name (ἐπωνύμως) for the notion (λόγος, λόγος), for example, that day is the passage of the sun above the earth: for it is manifest that he who has spoken of the passage of the sun has also mentioned the sun. So that he who has employed the word day has employed the word sun. A third way is, if that which is opposed in division is defined by that which is opposed in division, for example that odd is greater than even by a unit. For things of the same genus opposed in division exist by nature, and odd and even are opposed in division: for both are differences of number. (Trop. vi. 4.)

To know what a thing is, is the same as to know why it is. What is an eclipse? Privation of light from the moon through the earth intercepting the light.) What causes a conflagration? Privation of the sun and the light falls, owing to the interposition of the earth. What is symmetry? A proportion (λόγος) of numbers in sounds high or deep (ψύχων, ψυχή). Why is the high symmetrical with the low? Because of the proportion of high and deep. Hence it is a proportion (λόγος) of numbers. (Analyst Post. ii. 2.)

(60.) We seek the cause after we know that a thing is; but sometimes they are manifest at the same time also; but it is not possible to know the cause before we know that what thing exists. (Analyst Post. ii. 8.) For it is impossible to know what a thing is when we are in ignorance whether it exists or not.

And both the notion or expression (λόγος) appears to give evidence to phenomena, and phenomena to the notion. (De Coel. i. 3.)

(62.) The cause is the middle (μέσον), and in all things this is sought to be known before we know the cause. (63.) Not only that a thing 'is' ought the definition (ἀποδεικτικός λόγος) to show, as the most part of definitions declare, but the cause also ought to be in it, and to be clear. But the notions of the definitions are as conclusions: for example, what is quadrature? It is a rectangular equilateral figure being equal to a figure of unequal sides. And such a definition is an expression of the conclusion. But the definition which says that quadrature is invention of a middle, states the cause of the thing. (De Animal. ii. 2, § 1.)

(64.) And it appears that not only what a thing is, is useful towards knowing the causes of the accidents of essences (καθαρτικός λόγος), but also the cause (καταλαβεῖν) of an accident (καταλαβεῖν) of an accident is most useful, when a straight line is and what a curved line is, or what a line and a plane are, is useful towards seeing how many right angles the angles of a triangle are equal to, but conversely also the straight line and the plane are ground of the cause of that thing is: when we are able by the appearance (φαινόμενον) to give an account of the accidents either of all or of the greater part, then concerning the essence also we shall be able best to speak: for of all demonstration what a thing is (οἷον εἴσται), is the beginning. So that in all definitions in which it does not happen that we can recognise the accidents, and cannot even form a conjecture of them easily, it is manifest that they are all enunciated dialectically (διαλεκτικός) and emptily (σωματικός). (De Animal. i. 1, § 8.)

(65.) And of some things some other thing is the cause, and of other things not.

Accordingly manifest that of those also which belong to the class of what a thing 'is,' some are immediate (Διάφωσις) and first principles (τέχνη), which we must assume (πρωτεύοντα) both to be, and we must assume what they are, or in some other way make clear which the archetypal does for both what unity is and that it he assumes. But as to those things which have a middle (μέσον), and of which we have said a little, there is the cause of the essence, we can, as we have said, show by the definition (λόγος) which the archetypal does for both what unity is and that it he assumes. But as to those things which have a middle (μέσον), and of which we have said a little, there is the cause of the essence, we can, as we have said, show by the definition (λόγος) which the archetypal does for both what unity is and that it he assumes. But as to those things which have a middle (μέσον), and of which we have said a little, there is the cause of the essence, we can, as we have said, show by the definition (λόγος) which the archetypal does for both what unity is and that it he assumes. But as to those things which have a middle (μέσον), and of which we have said a little, there is the cause of the essence, we can, as we have said, show by the definition (λόγος) which the archetypal does for both what unity is and that it he assumes. But as to those things which have a middle (μέσον), and of which we have said a little, there is the cause of the essence, we can, as we have said, show by the definition (λόγος) which the archetypal does for both what unity is and that it he assumes. But as to those things which have a middle (μέσον), and of which we have said a little, there is the cause of the essence, we can, as we have said, show by the definition (λόγος) which the archetypal does for both what unity is and that it he assumes. But as to those things which have a middle (μέσον), and of which we have said a little, there is the cause of the essence, we can, as we have said, show by the definition (λόγος) which the archetypal does for both what unity is and that it he assumes. But as to those things which have a middle (μέσον), and of which we have said a little, there is the cause of the essence, we can, as we have said, show by the definition (λόγος) which the archetypal does for both what unity is and that it he assumes.
tion is proposition (δύναμις); for the arithmetician lays down (ποιεῖ, πόσα, πόσον) that the unit is indivisible, as far as quantification is concerned; it is not the case that a whole number is something in which a unit is and that there is a unit not the same thing. (Analys. Post. i. 2.)

(67.) All demonstrative science is about three things, two of which concern the propositions and one that concerns the affections (νοηματικά) of which by themselves it contemplates, and what are called common axioms (διάλεξις) from which first principles science demonstrates; and thirdly, the affections (δεικτικα) of which what each means it takes for granted. (Analys. Post. i. 10.)

(68.) It is clear that it is not possible to demonstrate the peculiar first principles of each thing: for those first principles of each thing about which each man knows in common knowledge, and of those is that which is supreme over all. For he knows more who knows from the higher causes: for he knows from the prior when he knows from causes which depend not on other causes. So that if he knows more and more, then science also will be both more and most. (Analys. Post. i. 9.)

(69.) Accordingly it is impossible to science from demonstration, if a man does not know the first principles which admit of no middle (κατὰ τὸ κατάτατον), but as to the knowledge of things which want a middle, a man may be in doubt. All animals have an innate discerning faculty, which men call perception (αἴσθησις). As and they have in common knowledge of the thing perceived (αἴσθησιν) and in others there is not. In those animals, then, in which it is not, there is either wholly, with respect to things of which there is no perception in them, a lack of knowledge except in so far as they receive: but in those animals in which there is, there is the faculty of having the perception in the mind, though they do not then perceive it. And many animals being such, there results a difference among them, so that they have reason owing to the permanence of such things, and some have not. Accordingly from perception comes memory (μνήμη), as we call it, and from the frequent remembrance of the same thing comes experience (εμπειρία): for many remembrances in number are one experience. And from experience, or from a whole thing remaining tranquil in the mind as one thing apart from the rest of all things is as one and the same thing, is the beginning of art and of science; if about production (παραγωγής), of art; if about that which is or being (εἶναι, τὸ σώμα), of science. Neither indeed do the faculties (εἶδος) exist in the mind separate, nor do they proceed from other faculties which are more intelligent, but they proceed from perception; as in battle a flight has taken place, when one stops, another stops, and then another, until order is restored to the army. For each faculty is a family of something that is a faculty of being so affected. For when one thing of things which are not different stands, it first of all is in the mind as universal (for the mind perceives the individual, but the perception belongs to the mind), just as the angels are compassed close by the multitude, but not to a man (κόιλος): and again it abides in these until the undivided and the universal have abided: for example, such or such an animal abides, until animal generally abides; and many men have experienced such and such a thing. It is manifest that it is necessary for us to know the first things by induction: for perception also in this manner produces the universal in the mind.

And since of the faculties that concern the understanding (εἴδος), by which we learn the truth, some are always true, and some admit of falsehood, as opinion and reasoning (λόγιον ἐν λόγῳ); and since science and intellect (ἐπιστήμη καὶ σοφία) are always true, and there is no other kind of science more exact than intellect, and since the first principles are clearer than the demonstrations, and since all science is together with reason (λόγιον),* there can be no science of the first principles of each thing. The intellect, intellect must be intellect of first principles: and this appears both from considering these things, and that the beginning of demonstration is not so, therefore science is not the beginning of knowledge. For of no kind of truth which exists independent of science, intellect (σοφία) must be the beginning of science. (Analys. Post. ii. 19.)

ORES, DRESSING, &c. OF. [Mining, P.C. pp. 236, 240, 241; Cooper, P. C., p. 505; Tim, Manufacture of, P. C., p. 471.]

* The word λόγος is rendered 'ratio' by the Latin translation. Trendelenburg translates the passage thus: 'jede Wissenschaft aber mit einem grundsätzlichen Unterschied; das wollte man nicht unerwähnt lassen.' It may be understood as in No. 2. Argynus should be related to λευκής as ἡ τιμία to τιμία (telling, tending) to τίμιον (holy, venerable).
flowers, the peduncles longer than the linear lanceolate bracts, lanceolate simple filaments, linear glabrous barbs. The flowers are white, with a broad green longitudinal band externally. It is found in meadows and pastures in Great Britain, and is the _species_ of _Theophrastus_, _Hist. Plant._ 7. 2. 178; and the Bobbin alba of Pliny, 29. 6.

*O. pyramica*, Spiked Star of Bethlehem, has flowers in an elongated raceme; the peduncles at first spreading, after-what they are held erect; the flowers are disposed below with an elongated point. The flowers are of a greenish white, the segments of the perianth variable in breadth. The leaves wither before the stalk appears; they are lanceolate, serrate, short-petioled, and capitate at the top. It is easily distinguished from _O. alba_, and is common in Wiltshire, Bath, and in Sussex and Berkshire. This species is the _species_ of _Theophrastus_, _Hist. Plant._ 7. 10. 7. 11.

*O. mutans* has but few leaves in a lax nodding raceme; the peduncles shorter than the bracts; the flowers flat, membranous, and trifid; the lateral points acute, the middle one very short, bearing the anther; the leaves linear lanceolate; the flower large, white, and greenish externally. It is occasionally found in fields and orchards in Great Britain. It is the _species_ of _Diocereus_, 2, 201.

*O. maritima*, Squill, is described under _Squilla_, P. C. and _Scilla_, P. C. (Lindley, _Flora Medica_; Babington, _Manual of British Botany_; Burnett, _Outlines of Botany_; Fras, _Synopsis_, &c.)

**OBNUS.** (FRAZUS, P. C.)

**ORBANCIUM** (from *sponio*, a kind of vetch, and _spyrw_, to envelop, because the species grows on the roots of vetches, and were supposed to destroy them by strangulation), a genus of plants, the type of the natural order Orbanaceae. It has 2 lateral, undivided or cloven permanent sepals; a ring of withering corollas, the upper lip concave, notched, the lower reflexed, in three unequal wavy lobes; a gland under the ovary; the anthers sagittate with the lobes pointed at the base; the filaments almost as long as the lobe of the corolla, downy and anthers; the capsule ovate, pointed with 4 parietal parallel placents. The species are paraerect, usually simple, rarely branched, scaly erect herbs.

*O. macroscopos*. Greater Broom-Rape, has the sepal 2-nerved equally bid, nearly as long as the tube of the corolla, the corolla bull-shaped, vescicose at the base, in front arcuate; the lips wavy, obsolete denticulated (not fringed), upper lip helmet-shaped, scarcely emarginate; sides patent, middle lobe of the lower lip much longer than the lateral lobes; the stamens inserted at the base of the corolla, glabrous below, their upper part and the style glandular pubescent. This plant is a native of Europe, growing parasitic upon broom, furze, and other shrubs belonging to the _Furcales_ on a barren and dry soil. It is abundant in some parts of Great Britain. This plant is very bitter and is a powerful astringent. It has been used as a dye, in the production of other dyes, and applied externally as a deterrent to foul sore.

*O. minor*. Lesser Broom-Rape, has the sepals many-nerved, the lobes of the lower lip equal, the stigma bi-lobed. The lower lip purple, the stigma yellow when dry. It is found in Europe parasitical upon the roots of the _Timobium pratense_. Although it is sometimes very abundant, it does not appear to injure the crop of clover. It is constantly found in many parts of England with the clover crops.

*O. rubra* has the corolla glabrous, pubescent externally, and the upper lip internally, the lips acutely denticulated, the stamens inserted near the base of the corolla. It is a native of the north of Ireland and of Cornwall in England. It is a sweet scent, and is found parasitical upon the _Thymus serpyllum_, Thyme.

*O. carpophylla* has the corolla tubular, bell-shaped, curbed, on the upper lip 3 lobed, toothed; the flowers inserted above the base; the corolla hairy within. The stigmas are of a dark purple, the anthers at first purple, yellow when dry. It has been found in Siberia and Italy, and on the Himalaya. It has been found also in England, where it is parasitic on the roots of _Galium Mollugo_.

*O. dactylus* has the corolla curved, tubular, slightly compressed above; the upper lip 2-lobed, toothed; the lobes inflexed; the margin toothed, in dyer's recipes, inserted above the base; the corolla scabrous. It grows in Great Britain, but is a rare plant.

*O. barbata* has the middle lobe of the lower lip of the corolla bright yellow. Found in Europe, parasitical upon ivy (Hedera Helix). Two other British species, _O. caerulea_ and _O. ramosa_ are described by Babington. These are referred by many systematists to the genus _Orobanche_, and _Orobanche_ is distinguished from _Orobanche_ by the possession of a tubular bibracteate, 4-5-toothed or 4-5-cleft calyx. _P. coerulea_ has a calyx of 4 sepals, tubular, with triangular subulate tooth shorter than the tube of the corolla; the corolla tubular, slightly curved in front, the middle of the tube compressed on the back; the throat slightly inflated externally; glandular lobes of the lips oblong with reflexed margins, lower lip hairy within, nature of the anther hairy. It is found in the north of Germany and the south of France. It has been rarely found in Great Britain in the fields of Hampshire and Norfolk, and in Jersey. The flowers have a bluish colour. It is parasitical upon _Achillea_ and _Spartium_. There are several other species of _Phelippea_, which were formerly described as belonging to the genus _Orobanche_. All the plants belonging to _Orobancheaceae_ have the habits and general character of _Orobanche_. The genera belonging to this order are distinguished as follows:

**Tribe I.**

**Orobancheae.** Parasitical leafless herbs.

1. **Orobanche.** Calyx bracteolatus, somewhat 1-2-parted.
2. **Phelippea.** Calyx tubular, bibracteate, 4-5-toothed or 4-5-cleft.
3. **Amphilophyllum.** Calyx bracteolatus, 4-cleft, sub-bibracteate.
4. **Bochkenia.** Calyx truncate, unequally 5-toothed.
5. **Camphora.** Calyx ventricose, 5-parted, bibracteate, corolla incurved; upper lip entire, lower one bifid.
6. **Epipogium.** Calyx 5-cleft, tubular, bibracteate.
7. **Lambro.** Calyx bibracteate, campanulate, 4-cleft.
8. **Hyobanche.** Calyx tubular, 7-cleft, unequal, bibracteate.
9. **Aeolus.** Calyx bibracteate, bracteolus; upper lip 2-cleft, lower one entire.
10. **Equisetum.** Calyx spathaceous, capsule many-celled.
11. **Amblystegium.** Calyx campanulate, 4-cleft, both lips of corolla entire.

**Tribe II.**

**Orobolae.** Terrestrial leafy plants.

12. **Orobolus.** Calyx 5-cleft, bibracteate, corolla campanulate.
13. **Tussia.** Calyx 5-toothed, bracteolus (7) corolla ringent, tubular; capsule 1-seeded by abortion (7)

(Don, _Gardener's Dictionary_; Lindley, _Vegetable Kingdom_; Babington, _Manual of British Botany_.)

**ORBUS.** (Vieche, P. C.)

**ORIS ROOT.** (Irish, P. C. S.)

**ORSOVA.** (Servia, P. C.)

**OBTN.** A genus of plants belonging to the natural order Filices, and to the sub-order Ombilicaceae. It has clustered these arranged in a branching spike terminating the frond.

*O. scopala*, the Flowering Fern, has bipinnate fronds, pinnales oblong, nearly entire, dilated, and slightly suriicted at the base; the clusters panicled, terminal. This fern is a native of Great Britain in boggy places, and often attains a height of from 1 to 8 feet. It is very common in many parts of England, and especially on the lakes of Killarney in Ireland. It is common throughout Europe, and a plant of the same name is found in the United States.

(Babington, _Manual of British Botany_; Newman, _British Fern_.)

**OSSIFEROUS BRECIA, OSSIFEROUS CAVERNS.** The existence of large fissures and caverns in the rock is a fact known to miners and quarrymen in all parts of the world; that these cavities are frequently filled with stalactitical sparry and earthy accumulations, and sometimes with the bones of animals, is another fact on which modern geologists have based a long train of ingenious inferences. Fully to examine these facts and inferences would be to discuss one of the most comprehensive and unsettled problems of geology; it is possible however to present in a small compass the leading conclusions arrived at, and the inferences drawn from them.

Great fissures and caverns, though not absolutely confined to limestone rocks, are yet by far of most frequent occurrence in these deposits. They are not common in all limestones, but have been observed in limestone of various positions which they occupy. It is peculiarly in thick masses of limestone, (whether magnesiforous or purely calcareous)
that we find great caverns in England, Ireland, France, Belgium, North Germany, the Tyrol, Carinthia, Italy, Greece, North Africa, North America, and South America. It is sometimes observed that great cavities abound in limestone rocks, not so much at near to points and lines where the ordinary position of the strata is violently disturbed by faults, or fissures, or through the accumulation of water. For while the numerous caverns of Derbyshire and Yorkshire, and the Mendip Hills, are situated in or near to situations of violently disrupted strata, and by accumulating observations of this nature are gradually come to receive, in many cases, a real dependence of the chasms in the rock on the fractures which have broken it.

But there are few caverns or great fissures all whose features can be explained. The disturbance has not so often produced the caverns as the conditions necessary for their production. On the contrary, in very many cases we perceive, even in caverns now dry, forms of interstitial surface which mark the decomposing influence of air and moisture, and the erosive power of running water. Through many of them water now runs, through more of them it formerly ran, conducted into the subterranean channels by the fractured condition of the strata. The great caverns of the Peak at Castleton and Buxton may be quoted as examples. Other caverns occur, nearly or entirely exempt from the direct influence of water, and in others where the course of water is known, as at Kirkdale in Yorkshire, a cave which has for great lengths an even floor and roof, and is connected, not with faults or axes of movement, but with great joints in the limestone. These caverns are marked by the joints. Water dropping, trickling, or running through the fissured limestone rocks dissolves (by the almost constant carbonic impregnation which it derived from the atmosphere and decomposing vegetation) its calcareous channels, and transports away, to the surface of the ground, the materials of petrifying springs, the tuberculous mounds of Matlock, and the travertine of southern Europe. In certain classes of limestone there is reason to conjecture that the great caverns have not been occasioned by violent fractures, yet new by the influence of joints, but that they are a part of the original structure of a coral reef (in which cavities were left by the polynoids builders), or have been generated by those chemical processes which we have as yet imperfectly traced and classed as metamorphic effects. This may be the case in certain magnesiferous (dolomitic) limestones in Derbyshire, France, and those caverns.

In regard to the filling of these cavities, we must again, in a great majority of instances, appeal to the action of water—an inverse action, new circumstances causing water to deposit where once it was evaporated; or an antecedent action, occasioning new accidents. Stalactical depositions and many varieties of sparry accumulations, which are now happening in caverns and lakes, confirm the former case, and as an instance of the latter we may describe what is known as the great North Yorkshire coast. Here the chalk is cavernous; the caverns, connected above with small fissures reaching to a mass of diluvial earth, have been filled for the most part by the water falling from waves and spray of the sea, and sometimes their roof, thus weakened, falls in, and the diluvial masses from above pour down into the cave, but are soon removed by the agitation of the tide.

Another instance is of familiar occurrence in the mining districts of the north of England, where limestone, more or less cavernous and fissured, is covered by shales or argillaceous toesands. Near the edge of these argillaceous beds, many rather regular pits (clay hollows) occur, through which the surface drainage reaches the limestone, and carries into its cavities some of the materials which are diloged in its course.

The geologist, who takes into consideration the possible origina of caverns in limestone from original hollows, the influence of joint fissures, and the effect of violent displacements; and considers further the various degrees and circumstances under which a cavern is formed, or the various action of water within them, their level in relation to that of the sea, and the nature of the strata or other matter superincumbent on the limestone, will be at no loss to comprehend how diverse, complicated, and variable are the processes of the earthy and earthy contents of subterranean cavities. These contents have in some cases fallen, in so as to constitute confused heaps or masses of breccia; in other cases they have been drifted by the waters, or have been washed away by storms, or have been dissolved, and deposited in crystallized and stalagmitic forms.

The occurrence of bones in these caverns, sediments, and stalagmitic incrustations is sometimes to be explained by supposing them to have been washed down by streams, or to have been drifted with sediments by water; but in a considerable proportion of the cases which have been examined there is no avoiding the conclusion that animals retired by the waters, or drifted into these cavities, and have left their bones in these cavities, and there have left their bones. This conclusion, established by the magnitude of Buckland for the hyena caves of Kirkdale and Torquay, applies to the numerous bear caves of the Harz, France, and Westphalia, and to the bear caves in Brazil and Virginia. It is a conclusion of the highest importance in geology and zoology. It assures us of the habitat of many extinct races of quadrupeds, and thus furnishes authentic data for a survey of the geographical distribution of Mammalia in one definite period of great antiquity, under which and climatic conditions of the globe much different from what it now is. Thus for instance we find among the perished races of British quadrupeds, the lion, hyena, and bear; the elephant, rhinoceros, and hippopotamus; the urus and the elk.

To allow of the introduction of these animals to Britain, we must suppose this island joined to the continent; to allow of their long continued existence here (which the phenomena in Kirkdale cave substantiate), we must suppose certain climatic and physical conditions. Practically, the great caverns of Kirkdale, near Kendal, in Yorkshire, are remarkable, having a general phenomenon, extending over a great part of the northern zones of the world, and of such startling magnitude as to have suggested hypotheses of diavilic catastrophes, and glacial periods, to geologists; while zoologists may perhaps regard it as a great example of the law of limited duration and successive predomination, to which, judging from the whole course of paleontological discovery, all the races of the animal creation must submit. The reader may consult, for the facts and inferences thus briefly noticed, Cuvier, Osservazioni; Buckland, Relazioni Diluviane; Meyer, Paleontologia; Owen, On British Fossil Mammalia, in Transactions of the British Association, and a variety of Memoirs by different authors in the Transactions and Proceedings of the Geological Society of London.

Ostracion [Schickel, P. C. S.].

Otterm, Karl Theodor, an architect to whom Brunswick is indebted for what ranks almost among the largest, and certainly among the most elegant palaces in all Europe, was born in that city, January 19th, 1800. He was the son of a physician, who intended him for the same profession; but his father's death leaving him free to follow his own inclinations, he made choice of architecture as his future profession. He studied architecture at the Polytechnic Institute at Berlin, 1812; and was compelled for a time to earn his living by the production of drawings and plans and by erecting the theatre there, called the Konsigstaed Theatre, which was begun in July 1823, and opened in the August of the following year. This decided success on the part of one so young—it being in fact his coup d' essai,—brought Otterm forward: henceforward it should, however, be mentioned that, although he was not known at the time, his designs were corrected by Schinkel. [Schickel, P. C. S.]. In his next work of note, the 'Sing.-academie' at Berlin (erected 1826-7), his design obtained preference of that of Schinkel, although the latter was in every superior taste, and indeed, one of the happiest ideas of the great master, as may be seen by the published drawings of it in his "Entwürfe," &c. As all this was, it was not without its disadvantages, as by immersing him too early and too completely in matters of mere business, it hindered that calm application to study which is so important to an artist at the outset of his career, and besides being spoilt by the exaggerated praises bestowed on his first efforts,—praises which, it has been suspected, proceeded partly from a desire to lessen the reputation and keep down the price of the work. Fortunately, he found it necessary for improving himself; and after first studying a short time in Paris, he visited Italy, where he remained nearly two years (1827-9); and where he was so far inspired as to complete and give the project and design of a building which should surpass every known edifice of the kind in extent and magnificence.
He was recalled to Germany by an invitation from Dresden, where he proposed to build a new theatre; and he proposed designs accordingly; but the scheme was dropped for several years, and then Semper was the architect employed on the noble structure since erected there. The designs produced at Dresden were the first of the several he made for him while he was at Dresden, a commission from the Duke of Saxo-Meiningen to make others for a theatre and casino for him, and the buildings were forthwith commenced. On his return to Breslau in 1830, the first part of his 1st Architectonic Mittheilungen, containing plans, &c. of his Theatre at Berlin. At that time his professional occupation consisted of little more than his official duties as Hofbaumeister, nor was the actual erection of ever being of any work of importance, when during a popular tumult which took place in September, 1830, the palace at Brunswick was set fire to and destroyed. He was thereupon directed by the new Duke, Wilhelm (the successor of his brother Karl, who was expelled by the revolution), to make designs for rebuilding the palace; and the edifice was begun the following year, and prosecuted with such activity as to be ready for habitation in 1837. The principal mass is 400 feet in extent, by upwards of 200 in depth, and 80 high, and in the centre considerably loftier, though the design has not yet been fully carried out, the open colonnades intended to form a place before the principal façade not being yet erected. Still, should nothing further ever be done, this palace is a most stately and elegant pile as it is; and even now it has been objected to it that it is too extravagant and costly a sacrifice of public labour and expense; and he has been prodigiously beseeching for besides that he was obliged to supplant every department of the works personally, from first to last, he designed the numerous details both of the exterior and interior, which display considerable inventive power as well as refined taste. The principal entablature of the exterior—extending altogether two thousand feet in length—is entirely of crimson, and much equally excellent and novel construction is displayed in other parts. The interior is distinguished by many striking pieces—the lower entrance vestibule, a Grecian Doric hall 150 feet in length; the parade staircase; the upper vestibule, a rotunda seventy feet in diameter, and sixty high; gallery; theatre; concert room; banquetting room, &c.

Besides the palace, Otter erected at Brunswick several other structures, both public and private, all of them, more or less, of architectural note: viz. the Theater-Intendantur, the Infantry Barracks, in the Florentine style, with a façade of 350 feet; the Iron Bridge, the Villa Bulow, New Richmond, the Schmitzhaus, the Interim Railway-station, &c. He also made a design for Cavalry Barracks at Brunswick, in similar style to those for the infantry; which design was published in Rosenthals' 'Zeitschrift für praktische Baukunst,' 1843, which is left behind him will perhaps remain unedited. Naturally of a delicate constitution, Otterm sank under the harass of business and the multiplicity of his tasks in the prime of life, August 22nd, 1843; but he lived to the hundred of the century, hardly would he have had such another opportunity as that afforded him by the Palace of Brunswick.

OVA, or as the name imports, egg-shaped, is the name given originally to such a form as the section of an egg presents, round, but not circular. In mathematics it has received some extension of meaning. Any curve, or isolated branch of a curve, which returns into itself, would be called an oval: perhaps even a figure of eight would receive the name.

The curve having for its equation

\[ y = \sqrt{x^2 - 4x + 4} \]

(a and b being positive; and a less than b) has an oval extremity. The new curve is to the origin x = b; but there is no curve whatever from \( x = a \) to \( x = b \), or from \( x = b \) to \( x = 0 \). If a be small, the dimensions of the oval are small: and when \( a = 0 \) the equation becomes

\[ x = \sqrt{y^2 - 4y + 4} \]

in which the oval has become a point (the origin), and is a conjugate point (Curve, P. C.), an isolated point which is not on any continuous branch.

Some conjugate points have none but imaginary values of \( dy/dx \), some have one and some two, and in the case of

\[ y = x^2 - 4x + 4 \]

there is a conjugate point at the origin, and \( dy/dx \) is then imaginary; but when

\[ y = x^2 - 4x + 4 \]

there is also a conjugate point at the origin, but \( dy/dx \) is there. The meaning seems to be as far as we can judge from a few of the instances that when the oval during its diminution has axes which preserve a finite ratio to one another, so that its tangents fall in all directions, the ultimate value of \( dy/dx \) is imaginary. But when one of the axes diminishes without limit at a point and the other remains finite, the tangents of that axis, the tangents tend to assume one direction, there is an ultimate value of \( dy/dx \) which defines that direction. If our surmise be correct, a double or triple value of \( dy/dx \) at the conjugate point would indicate the existence of a star-shaped oval, or of one which tends to assume that form as it diminishes. But this, with other points relating to the singular values of algebraic functions, has yet to be fully considered.

OWEN, JOHN, DR., was born in 1616, at Stadham in Oxfordshire, of which parish his father, Henry Owen, was for some time minister. At the age of twelve he was admitted a student at Queen's College, Oxford, where he took his first degree in 1632. During the period of his university life he is represented as having so diligently applied himself to study that he never allowed himself more than four hours repose. In the year 1637, when he was an instance of illegal taxation (Hammond, P. C.), Archbishop Laud, the chancellor of the university, made some new regulations, of which Owen disapproved. He was thus obliged to continue to Oxford. Brought up by his father in the strictest school of Puritanism, he considered the new statutes an attempt to enforce the observance of superstitious rites. On leaving Oxford he accepted the invitation of William, Lord Buckhurst, Sir Richard Dormer, of Ascot in Oxfordshire, having been some time previous to his expulsion admitted into holy orders by Bishop Bancroft. He afterwards became chaplain to the Earl of Lovelace, of Holland Park, London, whom he remained till the outbreak of the civil war, when, as he warmly espoused the cause of the Parliament, he forfeited the protection of his patron. Left to his own resources, Owen retired to London, where he appears to have joined the non-conformists. In 1642 he published his first work, entitled 'A Display of Arminianism,' which soon recommended the author to the notice of the Parliament, and became a prescriptive of his political views. Shortly afterwards presented by the committee appointed to purge the Church of scandalous ministers' to the preferment of Fordham in Essex. He enjoyed this living little more than a year, having been deprived of it by the patron, to whom it had reverted on the death of the sequentor incumbent. The Earl of Warwick then bestowed upon him the living of Coggleshott in the same county. Owen had not been long at Coggleshott before he abandoned the Presbyterian party to join that of the Independents. On the 29th April, 1646, one of the frequent fast days instituted by the Puritans, he was called to preach before the Parliament, and his sermon, on that occasion, 'on the necessity of one man's judgment being more prevalent than was prevalent among his party at that period. He still more strongly manifested his tolerant disposition when he was appointed to the critical task of preaching before the same assembly after the battle of Edgehill, which was not long before.

In this sermon he solemnly warns his hearers against oppression, self-seeking, and persecution. On the 26th February following, a day set apart for humiliation and prayer on account of the intended expedition to Ireland, he was again appointed to preach before Parliament and the chief officers of the army; on that occasion, Cromwell, who heard him for the first time, pronounced so favourably of his exposition of his merit, that he named him his chaplain, in which capacity he accompanied the expedition. In 1651 Owen was, by an order of the Parliament, promoted to the dignity of dean of Christ Church, and the following year made vice-chancellor of the University of Oxford, Cromwell being at that time chancellor. He appears to have discharged the peculiarly difficult duties of this office with much moderation, and his conduct met with the approbation of many of the Episcopalian party. After holding it five years, on the death of Cromwell he was deprived of it, as well as of his deanship, to which Dr. Reynolds, a Presbyterian, was appointed.

At the time Owen retired to small estates, which he had purchased in his native place, where he employed himself in preaching as often as an opportunity was afforded him. He was, however, soon obliged to abandon an occupation to which he had accustomed himself, particularly to the administration of the militia, and he determined upon settling in London. It was there that he published a work entitled 'Flat Lux,' in answer to the writings of a Franciscan friar, which attracted the
attention of Lord Clarendon. This statesman, who was anxious to reconcile the most moderate of the non-conformist party (H. R. P. C.), offered Owen immediate preferment if he would conform; which proposal, however, was firmly, though respectfully, declined. He then formed a congregation, among which he assiduously laboured, and in conjunction with Baxter, Bates, and other leading men of his persuasion, insisted upon the necessity of the restoration of the church of England. De Carbon contracted a second marriage, by which he was enabled to live in comparative affluence on an estate at Ealing, in Middlesex, where he died on the 24th of August, 1683.

The species described by De Carbon has equally been admired by those who were united with him by similarity of religious feeling, and by those who differed most widely from him in opinion; and it is not surprising to the temperance of his language and the mildness of his disposition. This character is a great measure reflected in its works, which, though strongly tinted by the peculiarities of the Calvinistic system, are not capable of their devotional spirit and are calculated to encourage practical piety. He certainly belonged to that section of his party whom Lord Clarendon designates as 'the more learned and rational.' (Clarendon 'History of the Rebellion,' vol. v. p. 513; see Warburton's note.) His works are very numerous among the best known of those not already alluded to may be mentioned: 1. his 'Exposition of the Epistle to the Hebrews;' 2. 'A Discourse on the Bible;' 3. 'A Discourse on the Book of Job;' 4. 'An Answer to T. Beddow,' 1655; 5. 'An Examen de l'Innommé, a Dieu Nécessaire, d'Orta, Progressus et Studio Sere Theologi,' 1661; 5. 'An Examen of the Psalms,' 1660; 6. 'On the Doctrine of Justification,' 1668; 7. 'A Discourse on the Book of Job,' 1668; 8. A large collection of Sermons and Tracts. His last production was 'Meditations and Discourses on the Glory of Christ,' which it is stated was sent to the press the day he died.

(For further particulars of his life and writings the following works may be consulted: 'Biographia Britannica,' vol. v., London, 1709; 'Memoirs of the Life of Dr. Owen,' prepared by a collection of the most eminent Dr. Owen, 1721; and Wood's 'History and Antiquities of Oxford.')

OWNERSHIP. (PROPRIETY, P. C.)

OXYRA (from ἀκρός, sharp, acid; the leaves have an acid taste), a genus of plants belonging to the natural order Polygemon. It has a 4-parted perianth, the 9 interior segments larger; 6 stamens; 2 stigmas; a 1-seeded nut, compressed, with a membranous wing, larger than the persistent segments of the calyx. O. reniforme, Mountain-Sorrel, is the only species. It is found on the highest mountains of Great Britain, and is an inhabitant of Europe. It is the O. dysphania of many botanists.

OZONE (from the Greek ὀξυς, to smell) is the name given by Professor Schönbein of Basel to an odour evolved during the progress of certain spiro-cyclic decompositions. It is also produced by common electric sparks, and by the working of an ordinary electrical machine in the air. This odour attracted no particular notice until M. Schönbein called the attention of the British Association to it in 1840, since which time it has undergone much examination, and various theories have been propounded as to its nature and composition.

Ozone is evolved at the anode, or positive pole of a galvanic battery, at the same time with oxygen, during the electrolytization of any of the following bodies, viz. water, dilute sulphuric acid, solutions of phosphoric and nitric acids, potas, and many oxides. Of these substances, sulphuric acid yields it in the greatest quantity. It may also be obtained from atmospheric air, oxygen, nitrogen, hydrogen, carbonic acid, and nitrous acid, by passing the electrodes through the latter after the electrification is continued and frequently making and breaking contact. Under the influence of heat ozone disappears, and it cannot be obtained from heated solutions, or solutions of hydricants, chlorides, and carbonates of metals. The gradual evaporation of these quantities, prevents its evolution from solutions otherwise yielding it abundantly. It may be developed by electri-lyzing a solution of muriate of soda with platinum electrodes, by placing the gas collected at the anode over ammonia and water to absorb the chlorine. Ozone can be preserved for a length of time with the oxygen collected with it in well closed bottles. It possesses the property of bleaching limewater and paper coloured with indigo or a solution of that substance. It is readily absorbed by mercury and the oxidizable metals, forming oxides with them; and when the solutions employed are heated, its affinity for metals is so greatly increased that it combines with platinum and gold. Water absorbs it. The inspiration of ozone is very injurious, and the effects similar to those resulting from chlorine and bromine. It killed several persons in Athens, Greece, as well as of Japan, Mexico, North America, and Europe. The flowers are yellow; those of the North American plant are larger than the European. The gases above are formed only when the unbehindful peduncles rather shorter than the leaves. It is native of North America, and is naturalized in Cornwall and Devonshire in England. The flowers are yellow and about the size of those of O. coromandelica. This plant is native of Java, and he recommends it as a pleasant cooler and diuretic; formerly P. C. S., No. 135.
are obtained: with platinum electrodes the odour is very powerful; but it is not produced when copper, zinc, or iron electrodes are employed. With boxwood charcoal the gas given off from the positive pole has no smell; but when absorbed by lime-water it turns it milky, proving the gas to be carbonic acid. With gas charcoal, sulphuretted hydrogen is evolved at the negative pole and carbonic acid at the positive; but no odour of ozone is produced. With a solution of mutarasa of soda the odour is not perceptible until the gas obtained from platinum electrodes at the positive pole is placed over ammonia and then over the charcoal. The residual gas emits the peculiar odour.

There exists much variance in the experimental results with this new substance; and not less in the opinions concerning its nature. Professor Schönbein considers it to be a trioxide or peroxyde of hydrogen. Marignac controversy M. Schönbein's conclusion, that it is to be derived from the decomposition of nitrogen, as he obtained it from water free from this latter gas. Mr. Williamson would prove that it is a compound, and that hydrogen is one of its elements, he having obtained it from a salt of copper, and passing the oxygen with the ozone over metallic copper which had been reduced by carbonic oxide gas, a sensible formation of water resulted. His view of the subject is, that ozone is a higher oxide of hydrogen than water, although not the peroxide of hydrogen of T histard, which is not volatile like ozone, but inodorous and fixed. Mr. Gann remarks, I intend to think that this peculiar odour may be emitted from all metallic bodies in such a manner as to prevent oxidation or combination with other bodies; and that all metals have the power of emitting it, when put into a peculiar electrical state, that is, when the metals are in a state of transition previous to oxidation or combination; and Mr. Lake, who claims to have demonstrated that the electric fluid is a substance, to which he has given the name of pyrogen [P yroge, P. C. S.], considers that it is a compound of this substance with oxygen, that is, an oxide of pyrogen. He says, 'It would seem indeed the necessary inference of Mr. Gann's experiments (the evolution of ozone from oxygen and the other gases) that oxygen enters into the composition of nitrogen and hydrogen, for ozone is developed, except in these two instances, from oxygen and its compounds, by the combination of oxygen with pyrogen, and hence it would follow that nitrogen and hydrogen contain oxygen.'

The inquiry concerning the substance is of great importance to chemical science, as it involves the question of the nature of oxygen, hydrogen, and nitrogen, from each of which it can be obtained. It is agreed by all that oxygen is one of the elements of ozone. If, therefore, hydrogen is the other, it follows that oxygen is a compound into the composition of which hydrogen enters; that oxygen is an element of hydrogen; and that both oxygen and hydrogen are elements of nitrogen, since ozone can be evolved from each of these gases: and it is to be remarked that this last circumstance agrees with Mr. G. J. Knox's discovery, that nitrogen is a compound of hydrogen and silicon. This also overthrows M. Marignac's opinion, that it cannot be obtained by the decomposition of nitrogen, and confirms M. Schönbein's to the contrary effect.

Mr. Gann's opinion, in substance and as far as it goes, coincides with Mr. Lake's, for he considers ozone to accrue between the oxidation or combination of the metals with the substances exhibited to them and the time when chemical action commences. According to the latter, ozone must be present and of paramount importance in the processes of acidification and oxidation, for he shows that both oxygen and the electric fluid (which he considers the elements of ozone to be) are required to form an acid [Pyrogen, P. C. S.], and of course no oxide. If this view be correct it accounts for the disappearance of ozone where the more oxidizable metals are exhibited to it, and also for the formation of carbonic acid when acid solutions are electrified with carbon as the positive electrode.

Some singular phenomena connected with ozone were observed by Professor Schönbein, strongly indicative of its electric origin, if not of its electric composition. When perfectly clean and dry plates of gold or platinum are immersed in oxygen containing ozone, they acquire a negatively electric state of polarity. Silver and copper also become thus electric, but in a far less degree than zinc; and these plates thus polarized retain their electric powers in air for a considerable time, but rapidly lose them when plunged into hydrogen gas, in which, if retained a sufficient time, they acquire an opposite state, becoming positively polarized.

When a perfectly clean and dry plate of gold or platinum is exposed to an electric brush it becomes positively polarized, the degree of polarity depending upon the nature of the point and the time the plate is exposed to the brush issuing from it. This power may be attributed, according to the last of the above theories, to the formation of ozone by the combination of the electric fluid of the brush with the oxygen of the air. If the point from which the electric brush is issuing be moistened with water, the electricity still continues to be given off, but the power of polarizing the plates is lost, which effect is no doubt produced by the water absorbing the oxygen. Heat, which destroys, or exposure to hydrogen, which inverts, the electricity of a plate that has been polarized by exposure to oxygen containing ozone, exerts a precisely similar action on plates polarized by the electric brush.

(Proceedings of London Electrical Society, 1841-42, p. 160; Reports of the British Association, 1840; Polytechnic Review, New Series, vol. ii. p. 260; Athenaeum, 1845, pp. 690, 674, 723; Chemical Gazette, September, 1843.)

* According to Professor Schönbein, nitrogen is a combination analogous to hydrochloric acid, and is composed of ozone and hydrogen.

PACCIARIOTTO, JA'COPO, one of the most distinguished of the old Siennese painters, was born at Siena in the latter part of the fifteenth century; but though he has a chronology to the painters of the sixteenth century, he is one of the quattrocentisti in style; his works much resemble those of Pietro Perugino; at the same time they are more fully developed in form and of wonderful force of colour. His chief works, celebrated masterpieces, are:

He lived in Siena until the year 1535, when, owing to his being one of the principals in a conspiracy of the people against the government, he was compelled to fly, and he took refuge in France. Lanzi says that he would certainly have been hanged, had he not been protected by the Osservanti monks who concealed him for some time in a tomb. He succeeded in making his escape, and joined II Rosso in France, where he in all probability ended his days not very long afterwards, as nothing further is known of him, and he does not appear to have left any works in France.

There are still several excellent paintings, both in oil and in fresco, by Pacchiarotto, in Siena. There is a beautiful altar-piece in San Cristoforo; and some excellent frescoes in Santa Caterina and San Bernardino. Speth takes particular notice of these frescoes in his "Art in Italy," and terms Pacchiarotto the second hero of the Siene school—Lanzi, calling Sodoma, being the first. They are highly praised also by Lanzi. In Santa Caterina is the visit of St. Catherine of Siena to the body of St. Agnes of Montepulciano, in which are a host and figures worthy of Raphael. According to Speth these works can be justly compared with Raphael's alone, and he adds that designating Pacchiarotto as the head of the school of Perugino, is only magnifying the injustice he had already undergone in being reduced to the long report as the works of Perugino. If therefore he were the pupil of Perugino, what Perugino supplied was only the spark, says Speth, which in Pacchiarotto grew into a flame.

Pacchiarotto has suffered the same misfortune that many other excellent masters have undergone, owing to their being omitted by Vasari—their merits have remained long unrecognized. Pacchiarotto is probably the Girolamo di Pac his cousin was casually mentioned by Vasari in speaking of II Sodoma; they painted together in San Bernardino.

There are two beautiful small easel pictures in oil and on wood in the Pinciotheek at Munich by Pacchiarotto—San Francisco d'Assisi, with two angels in the background; and the Madonna and Child, with four angels in the background; half-length figures in both. They are two of the best pictures in the collection, in character, colour, and execution, and are among the best specimens of the beauties of the early Italian schools of painting. They were formerly in the church of San Bernardino at Siena, but were purchased and presented by the present King of Bavaria, Ludwig I., then crown-prince.

(Lanzi, Storia Pittorica, &c.; Speth, Kunst in Italien, vol. ii.)

PACHECO, FRANCISCO, was born of a good family at Seville, in 1571, according to his own account, which is nine years earlier than the date given by Palomino. He was nephew of Francisco Pacheco, canon of the cathedral of Seville, a distinguished divine and a celebrated Latin poet.

Pacheco's master was Luis Fernandez, a painter of severs &c. at Seville: he never was in Italy, as Palomino has wrongly inferred from two passages in his treatise on painting; he studied exclusively in Seville. His first works worthy of notice were two large flags or standards for the Spanish fleet of New Spain and Tierra Firme, painted in 1594, in oil on crimson damask, each thirty yards by fifty; the paintings were sewed on to the flags, and hung on the rich borders and other decorations. He was one of the principal painters employed on the great decorations of the funeral or catafalque of Philip II. of Spain in the cathedral of Seville in 1599. He was also the first, says Cona Bermudes, in Seville who properly painted and gilded statues—el primero en encarnar y estabar bien las estatuas; thin colour was painted over the gold. He was the first likewise who painted the figures of the Virgin and Child, which are several works of both descriptions by Pacheco in Seville.

In 1600 he was appointed, together with Alonso Vazquez, to paint a series of large pictures illustrating the life of St. Ramon for the cloister of the convent of the Merced. In 1603 he executed some works in damper in the palace of Don Fernando de Ribera, third duke of Alcalá, from the story of Dádulus and Icarus.

It was not till 1611 that he visited Toledo, Madrid and the Escorial, and saw the great works of Titian and other celebrated masters, and more closely studied the excellent works which he saw on this occasion impressed him forcibly with the varied and incessant application requisite to form a great painter. Accordingly upon his return to Seville he opened a systematic academy of the arts, as well for his own improvement as for the benefit of the rising artists of Seville; and the fact alone that Alonso Cano and Velasquez were two of his scholars, shows that his system worked with some effect. The improvement he himself acquired by such elementary instruction, and from the true principles of art, is shown by his great picture of the Last Judgment, an altar-piece finished in 1614 for the nuns of the convent of St. Isabel, which he has himself described at great length in his treatise on painting. Soulé made a magazine of this convent during his occupation of Andalucia, and the picture was probably removed. It was a large work containing many figures and many incidents, but Pacheco received only 700 ducats for it. On one part of it was inscribed 'Futurum ad Finem Saculorum Judicium Franciscus Paccies Romulense depingebat. Saeulos a judicis natali xxv. anno xi.'

In 1618 Pacheco was appointed by the Inquisition one of the guardians of the public morals, in as far as he was made censor of all the pictures which were exposed for sale in Seville; nakedness was prohibited, and it was Pacheco's business to see that no picture was sold which showed a naked female of the size of life, if of any other size. It reflects the jealous morosity of the Inquisition even in its portraits. Frudery was carried so far in Spain, that in the time of Ferdinand VII. even all the great Italian works which could be reproached with nudities were removed from the galleries, and were condemned to a distinct set of apartments called the Galeria Reservada, and only opened to view to those who could procure special orders. There is a 'Cabinet des Objets Réservés' at Naples, and though this is separated from the rest of the collection with reason, there is no difficulty whatever in obtaining admission into it; but the Galeria Reservada of Madrid is of a very different nature, and comparatively innocent, and the separation of such works from the general collection is a greater evidence of subjective immorality than objective immorality. Mr. Ford, in his 'History of Spanish Art,' terms this gallery a sort of Magdalen, or penitentiary, into which were banished all peccant pictures whose nudities might corrupt the purity of Madrid; where the Italian and Flemish Ledas, Danasés, and other improper ladies, blushed unseen, lumped together like the naughty epigrams of Martial when collected into one appendix in well-intentioned editions. All these pictures were the works of foreigners. 'Nothing,' says Mr. Ford, p. 116, 'gave the holy tribunal greater uneasiness than how Adam and Eve in Paradise, the blessed souls burning in purgatory, the lady who tempted St. Anthony, or the Last Day of Judgment, were to be painted, circumstances in which small-clothes and long-clothes would be highly misplaced. Both Palomino (ii. 187) and Pacheco (201) handle these delicate subjects very tenderly. Describing the celebrated Last Judgment of Martin de Vos, he remarks: 'It formed him that he had chanced, when only a simple monk, to perform service before this group of nakedness; the mitre had not obliterates the dire recollections; he observed (he had been a sailor) that on the day of judgment, when the last man mass before it again, he would face a hurricane in the Gulf of Bermuda; the moral effect of the awful Day of Judgment was so much counter-balanced by the immoral desolation.'

In 1623 Pacheco again visited Italy, and was visited by his distinguished scholar and son-in-law Velasquez, and he remained two years in the Spanish capital. Velasquez went
to Madrid by the invitation of the duke de Olivarres, who procured him the appointment of painter to the king, Philip IV. It was at this time that Velazquez painted his equestrian portrait of Philip, upon which Pacheco wrote a sonnet, in which he was compared with Alexander, and Velazquez with Apelles (Cena de Madrid, v. 1619).

Pacheco, during this visit to Madrid, among many other works, executed one which hardly accords with the present notions of the occupation of a great painter, though it has been the practice of great artists from very early ages to treat in their statues: it was common in the time of Plato and of Alexander. [Niclas, P. C. S.] Pacheco dressed, gilded, and painted (except for the duchess of Olivares, a statue mostly of wood, of the Virgin, by Juan Gomez de Mora, for 2000 reals. The work was much admired, and by none more than Eugenio Cazes, who, says Cean Bermudes, estimated the decoration at 500 ducats. What this process exactly was is not evident from this mere mention; but the object generally in these painted wooden images appears to have been to obtain an exact imitation in the minutest detail, perpetual femaleness. The effect of such images, called Pasos, must be experienced to be comprehended. The Spaniards dress them as well as paint them. Their churches were crowded with such works; but most have now been removed to private possession.

Pacheco returned to Seville, where his house became a chief resort of all men of art, of literature, and of taste, and among his most intimate associates were the Jesuits of Seville, who instilled into him a love for art, and who were indeed the authors of that part which is devoted to sacred art; and doubtless to them is due the austere morality which characterises Pacheco's principles of art. He is noticed above as having been a great lover of painted images. He published an essay partly on this subject in 1622, complaining of sculptors painting their own statues. But the generality of Donoradores and Estafadores worked so badly, that such sculptors as Juan Martin Montanes and Alonso Cano felt compelled to dress and colour their own statues. Pacheco however coloured many statues for Montesinos, including the St. Jerome of the monastery of Santiponce. Montesinos generally went with his employer to be allowed to superintend the toilet of his own statues. Mr. Ford gives some curious details about the toilets of these Spanish images. No man is allowed in Spain to undress the Pasos, or Sagrados Imagenes of the Virgin; and some images had their merrinesse of the robes (Camarena Mayor) and a chamber (Camara) where their toilet was made. The duty has, however, now devolved upon old maids; and ha quedado para vestir imagines—she who has gone to dress images, has become a term of reproach. Embroidering rich dresses for images of the Virgin is still a great occupation with the rich and pious ladies of Spain. Similar customs prevailed with the antients. But the great pride of Mr. Ford, paid much more attention to decorum and propriety of costume than the Spanish clergy. In the remote villages and in the mendicant convents the most ridiculous macaquedroles were exhibited, such as the Spaniards were wont to wear in their Ursulines, with wig, and cap, figures have only heads, feet, and arms, the bodies being mere blocks, because destined to be covered with drapery; they are called 'imagines a vestir.' Before the French occupation of Spain there were fifty of these images in Seville alone, which were carried in various processions in the holy week, and on other great occasions.

Pacheco died at Seville in 1654. His works, though not vigorous, are correct in form, effective in light and shade, studied in composition, and simple in attitude; but they have little colour, are dry, and rather feeble or timid in their handling. These defects are more apparent when his pictures are seen together with the works of other Andalucian painters, who have generally made colouring their principal study, and have comparatively neglected purity of form. Besides many religious pictures, he painted or drew in crayons nearly four hundred portraits, the best of which is that of his own mistress. One of his sitters also was Miguel Cervantes.

His Arte de Pintura, su Antiguedad, y Grandezas, 4to, Seville, 1649, pp. 641, a remarkably scarce book, is considered an indispensable study by the painters of Seville, and it is as far as is possible the perfect method of Seville. It is very elementary, and is said also to be a work of great learning on the subject, and is held throughout Spain to be the best work on painting in the Spanish language: it is in three parts, in modern Spanish verse, and does not contain any technical knowledge. His works are seldom seen out of Seville; and he is even very inadequately represented in the splendid gallery of the Prado at Madrid.

His masterpiece is, or perhaps rather was, the altarpiece of the Archangel Michael expelling Satan from Paradise, which was in the church of San Alberto at Seville; but this church was one of Souli's museums. There are still at Seville an altarpiece of the Conception at San Lorenzo, two pictures of San Fernando in San Clemente; and a picture in San Albano. The methodical system of Cean Bermudes to mention the locale of all the most celebrated works of the great Spanish masters, eventually cost Spain a greater portion of these works, for his dictionary was compiled by Cean Bermudes as an inventory of what was valuable, and directed them to the places where these works were to be found. Not a moiety of the works of Pacheco are mentioned by Bermudes as at Seville is now to be found there. Pacheco's own portrait by himself is in the Spanish museum in the Louvre.

Pacheco collected the poems of his friend Bernardo de Herrera, and published them with a portrait, in 1619. His own poems do not appear ever to have been published in a collected form. Bermudes has printed a few in his Dictionary. (Cean Bermudes, Dicionario Historico de los mas Ilustres Profesores de las Belleas Artes en Espana.)

PACHYCIORMUS, a genus of Ganoid fossil fishes, from the lias of England and Wurttemberg. (Agassiz.)

PACHYCEPHALUS, a genus of fossil fishes from Shropshire. (Trew.)

PACHYDODON, a genus of Dimyarian Conichthys, fossil in the lias and oolites. (Strickland.) This is the genus Cardinia of Agassiz, and includes part of the Unionide of Swainson.

PACHYPTERIS, a genus of fossil Ferns, from the oolite of Yorkshire. (Brongniart.)

PACKING-PRESS. The hydraulic press invented by Mr. Brunner, besides being used to draw piles, trees, and blocks from the ground, or to prove the strength of materials, is frequently employed to pack or compress bales of linen, cotton, and the like goods into small dimensions for the convenience of transport. The description of this machine has been given under HYDRAULICS, P. C.; and it is intended here merely to notice the method employed by Mr. Barlow to determine the thickness which the cylinder should have in order that its strength may be equal to the strain to which it is subject from the pressure of the fluid within it.

Within any horizontal section of the cylinder the tendency of the contiguous particles of metal to separate from one another in a direction perpendicular to a diameter passing through them, in consequence of the expansion produced by the pressure of the fluid, becomes continually less from the interior to the exterior circumference of the section, and is inversely proportional to the distances of the particles from the axis of the cylinder; and the cohesive power of the particles is, by the laws of elasticity, proportional to their separation, while the strain produced by the pressure of the fluid varies as the square of the distance from the axis of that part from the axis. It follows that the resistance opposed at such part of a section to the momentum of the pressure is inversely proportional to the square of the distance from the axis of that part.

Therefore r representing the radius of the interior surface of the cylinder, t the whole thickness, and x any variable distance from the interior surface towards the external, all in inches; then \( \int_{r}^{t} \frac{x}{(r^2-x^2)} \, dx \), if multiplied by \( \pi \), the circumference (rad. = 1), and by the force of cohesion on a square inch of the metal, will express the resistance produced by an annulus which is one inch deep in a direction parallel to the axis.

That integral, for the whole thickness \( t \), is \( \frac{\pi}{4} t^2 \); therefore

\[ \int (\text{in pounds}) \text{ denoting the force of cohesion,} \quad \frac{2 \pi tf}{r^2-t^2} \]

expresses the whole resistance.

\[ \int (\text{in pounds}) \text{ represent the force on a square inch of the interior surface, by which the pressure of the fluid tends to strain the cylinder,} \quad \frac{2 \pi tf}{r^2-t^2} \]

will denote the whole strain on the same annulus; therefore, equating the strength and strain, there is obtained

\[ t^2 = \frac{\pi}{2} \frac{2 \pi tf}{r^2-t^2} \]

This value of \( t \) expresses the required thickness.

PACO. [LLAMA, P. C.]
PADDLES, PADDLE-WHEELS. [Steam-Vessels, P. 463, pp. 480, 486, 608.]

Familj Paddles contain plants belonging to the natural order Cincinaceae. It has a small 5-toothed permanent calyx, a funnel-shaped corolla, hairy inside, 5-lobed, and with a pilated stamnation. There are 5 stamens, some times 2 or 3 shorter, nearly sessile in the middle of the tube. The style is not prostrated, and the stigma bident. The berry is small, roundish, and globose, tr-angled, with a seed in each cell. The flowers are white, small, and usually unclosed.

**P. ficoides** has a woody twining stem, round and smooth. The leaves are oblong or lanceolate, cordate at the base and glabrous. The panicles axillary, terminal, opposite, short, and the flowers are usually small and pink, the bracts ovate, the calyx 6-toothed, the corolla with a long tube somewhat gibbous and woolly inside; the limb narrow and divided into 5-cordate ciliate segments. The berry is dry, compressed, being 5 lines on each side, 1-seeded, and 2-seeded. The seeds are smooth, compressed, enlarged with a somewhat membranous ring all round. The leaves have a very fleshy and allaceous odor when bruised, yet they are used to impregnate baths and are administered in a decoction medicinally in cases of retention of urine and some febrile complaints. According to Roxburgh the root is used by the Hindoos. it is a native of the East Indies, and of Japan and the Moluccas.

**P. ternata** has an erect smooth trichotomous stem with triangular branches; leaves 3 in a whort; oblong lanceolate, the blades being divided into the calyx campanulate and obscurely 6-toothed. It is a native of the East Indies on the mountains which border on Silhet. The flowers are rather large, funnel-shaped, white, on long filiform pedicels, each pedicel having a pair of linear ciliate bracts above the middle. The flowers are said to be fragrant when fresh, but emit a very offensive smell on being steeped in water after they have been dried.

The species of Paederia are free growers and will strike root in any kind of light rich soil under a hand-glass. (Don, Gardener's Dictionary; Lindley, Flora Medica.)

**PAGANI, GREGORIO.** was born at Florence in 1500; his father, Francesco Pagni, died aged only thirty, when his son was but three years old. Gregorio was an excellent colourist, who first the pupil of Santi Titi, and afterwards of Cigoli, and became one of the first and most able re-formers of the Florentine school from the low state to which it had been reduced by the blind followers of the anatomical school of Michael Angelo. (Tuscan School of Painting, F. C.)

Bargelli had a school of his own, but Cigoli was its principal representative, and Pagni adhered so closely to the style of his friend and master Cigoli, that he used to be termed the second Cigoli. His masterpiece, however, was the painting of the Virgin in the Cappella di Firenze, was burnt in the fire which destroyed that building in 1771, and Pagni's reputation has greatly suffered in consequence, though there is a print of it by G. B. Cecchi and B. Angelini. It was once the centre of a fresco in Santa Maria Novella: its easel-pictures in oil are also rare. He died at Florence in 1605: Matteo Rossini was his scholar.

**PAGANTINI, NICOLÒ**, whose European fame as a violinist, whether justly acquired or not, entitles him to notice among distinguished characters, was born at Genoa, in 1784. His father, a commission-broker, played on the mandoline, but fully aware of the inferiority of an instrument so limited in power, he put a violin into his son's hands, and initiated him in the practice of his art. He was conducting a band and so well under parental tuition, that at eight years of age he played three times a week in the church, as well as in the public salons. At the same period he composed a sonata. In his ninth year, he played before the Society of Oratorio of Genoa; then had lessons of Rolla, a famous performer and composer; and finally studied counterpoint at Parma under C. Doni and A. Guglietti, and the celebrated maestro Farinelli. He now took the Emperor Josephine to Bavaria, and went with her to Russia, where he was presented to the Empress, and himself invited to the full extent of her means, superior talent of every kind. In 1813 he performed at Milan; five years later at Venice, and subsequently at Florence and Naples. In 1828 he returned to Vienna, where a very popular violinist and composer, Mayeck, asked him how he produced such new effects. His reply was characteristic of a selfish musician:—"Chaucer's advice," said he. "In that capital he was accused of having murdered his wife with his own sword, and of having married, which could not be produced. Then he was charged with having polygarned his mistress. This is the public explanation. The fact is, however, how to make money from friends wherever his thirst of gold led him. Avarice was his master-passion, and, second to this, gross sensuality in his intercourse with the female sex.

The year 1831 Paganinni in the usual style of a virtuoso capital he produced a sensation hardly inferior to that created by the visit of a truly great musician, Rossini. Even this renowned composer was carried away by the current of popular opinion. Being asked how he liked the new violinist, he replied, 'I have wept but three times in my life: first, on the failure of my earliest opera; the second time, when in a boat with some friends, a turkey stuffed with truffles (undine doletrues) provided for our dinners tumbled into the water; and, thirdly, on hearing Pagnianni for the first time.'

The public of Brussels, however, were moved in a very different manner. According to M. Félix, Paganini's performance at a concert by him in Brussels, was the despair of the whole of the town. He arrived in England in 1831, and immediately announced a concert at the Italian Opera-House, at a price which, if accorded to, would have enabled him to be the first of the Continent, of the gullibility of the British public, of the wealth of the aristocratic classes, and of their lavish expenditure on foreign performers; but the attempt was too cautious, even for those, and he was compelled to abate his demands. Though he succeeded in drawing audiences fifteen nights in that season at the ordinary high prices of the King's Theatre. He also gave concerts in other parts of London, and performed at walks which were taken at the end of the proceeds, and frequently the whole. He visited most of our great towns, where his good fortune still attended him. He was asked to play at the Commemoration Festival at Oxford, in 1854, and demanded 1000 guineas for his assistance at three concerts. Need we add that his terms were scornfully rejected?

Paganini died at Nice in 1840, of a diseased larynx (ataphis laryngis). By his will, dated 1837, he gave two of his sisters legacies of 60,000 and 70,000 francs; his mother a pension of 1200; the mother of his son Achillino (a Jewess of Milan) a similar pension; and the rest of his fortune, amounting to four millions, devoted to the establishment of schools and other objects before related, we give on the authority of the Biographie Universelle.

Paganini certainly was a man of genius and a great performer. His bowing was always pronounced by the masters of the violin and of music to be one of the most remarkable ever heard. His fingers were so sensitive that he could play with his middle finger as if it were the violin almost marvellous, though he made an ignoble use of his power by employing it to captivate the mob of pretentious amateurs by feats little better than sleight-of-hand. His performances in London and Paris, his playing of some of Beethoven's and other compositions, were very extraordinary; but why, as was asked at the time, be confined to one string when there are four at command that would answer every musical purpose so much better? His tone was pure though not strong, his strings having been of smaller diameter than usual, to enable him to restrain them at pleasure; for he tuned his instrument most capriciously. He could be a very expressive player: we have heard him produce effects deeply pathetic. His algæ gies evinced his knowledge of harmony, and some few of his compositions exhibit many original traits. But money was his object, and he attained it. Were the French, continuing their not uncommon practice, to put the principal incidents of Paganini's life into a dramatic form, "All for gain, or fair fame well lost," would make an appropriate title to the piece.

**Biographie Universelle**

**PAGGI, GIOVANNI BATTISTA.** was born in an ancient and noble family at Genoa, in 1564. He was the pupil of Luca Cambiaso, and was distinguished chiefly as a painter, but he was also a very dexterous designer and etcher. In 1585 he was ordered to fly from Genoa in consequence of an unfortunate homicide which the absurd conduct of a friend brought upon him. Paggi went to France, and, under the protection of the great-duke of Mantua and Ferdinand, lived in ease and reputation, until he was recalled through Archbishop Sisnudo, afterwards
cardinal, to Genoa about 1500, where he executed several excellent works, and gave a great impulse, especially in colouring, to the Genoese school of painting, of which he was the best master in his time. His masterpieces are considered two pictures in San Bartolomee, and the Slaughter of the Innocents belonging to the family of the Si- gismondo, painted in 1506. Paggi died in 1527. In 1607 he published a short treatise on the theory of painting, entitled 'Definitione, o sia Discezione della Pittura.' He wrote it in consequence of his objecting to those who, without being an artist and in his 'Trattato della Pittura,' 'Idea del Tempio della Pittura.' Paggi's treatise is extremely scarce.

(Soprani, Vite de' Pittori, &c. Genovesi; Lanzi, Storia Pittura, &c.)

PAJOU, AUGUSTIN, a distinguished French sculptor, was born at Paris in 1730, and was the pupil of J. B. Le- moune, likewise a sculptor of eminence. Pajou obtained the grand prize for sculpture in the French Academy, in 1748, and accordingly went as a pensioner of the French govern- ment to Rome, where he remained twelve years. Gabet mentions that Pajou was the sculptor of about two hundred works, in bronze, marble, stone, wood, and even in paper or pasteboard; and he gives a list of some of those which he ex- hibited. In 1768 he exhibited a sketch of the tomb of Sta- ino, at Rome, in marble and plaster, and in 1752 the statue of Louis XVI., and in 1758 the statue of Louis XV., a statue in lead, of the natural size, for the Duchesse de Ma- zarin, representing Love as ruler of the elements; and four large colossal figures in stone for the garden of the Palais- Royal in Paris, Mars, Cupid, Mars, and Apollo. The following are some of his principal works:—Pluto hold- ing Cerberus, claimed (for this work he was elected a member of the Academy); Psyche abandoned (in the Luxembourg); statues of the Dauphin, of Pomone, of Doublet, and of the sculptures of the façade of the Palais-Royal, ordered by Louis XVI. He executed also the sculptures of the Salle de l'Opéra at Versailles; the ornaments of the Palais Bourbon; and the阳性 of Orleans; and also the Noailles of the south and west faces of the Fontaine des Innocents. He died at Paris in 1809. He was made one of the professors of the French Academy of Arts in 1767; and was subsequently a member of the Royal Institute. His works were natural and manly, and was so far the exponent of his own character. His son Jacques Augustin Pajou was a painter of great merit.

(Gabet, Dictionnaire des Artistes de l'Ecole Française, &c.)

PALEOGRAPHY (from παλαιός, 'old,' and γραφή, 'writing') is a term applied to express the knowledge of the ancient styles of writing, or the study of the characters and illuminations of ancient manuscripts. Paleography is a com- paratively recent study respecting its ornaments, but it has very lately been the subject of much laborious application in all respects; and the age of a MS. may be now approximated from a few characters, though it cannot be strictly ascertained. The present article is directed particu- larly to the ornament and general illumination of ancient MSS., and their connection with the progress of painting, and is not to be confounded with the study of MSS. or the history of MSS., which is treated of in the 'Penny Cyclopædia.' The whole subject is perfectly illustrated, generally, in the splendid work recently published in Paris by Champollion Figeac, and Aimé Champollion, Fils, which contains fac-similes from most of the principal MSS. extant in Europe, admirably executed by Silvestre (Paléographie Universelle, Collection de Fac-Similes d'Écritures de tous les Peuples et de tous les Temps, par M. Silvestre, 1839-42, 4 voles, folio).

The first work which treats of this subject with regard to ornament is Diddin's 'Bibliographical Decamerion,' published in 1617, which was followed by the more comprehensive work of D'Agincourt in 1823, Histoire de l'Art par les Monuments, but which treats chiefly of Greek and Italian MSS., and the illustrations are uncourled. D'Agincourt was the first to pronounce the treasures of the Vatican Library in this depart- ment of art. A very beautiful work in colours, by Mr. Shaw, on this subject was published in London, in 1833, Illuminated Ornaments selected from MSS. and early Printed Books, from the Sixt to the Seventeenth Century, drawn and engraved by Mr. Shaw, with descriptive catalogue and an introductory essay by Sir F. Madden, keeper of the MS. in the British Museum. There are many papers on this subject in the Academy; and a series of articles on the Progress of the Art of Illumination in the Penny Magazine of 1839.

The illumination of MSS. was in practice among the ancient Romans. This is known from passages in ancient writers, though there are no MSS. extant of an earlier date than about the third century of the Christian era. Portraits were sometimes prefixed to the writings of authors: Martial (xiv. 186) men- tions one of Virgil which was prefixed to a MS. of his works; and Virgil himself mentions a MS. of his own works, and portraits of 700 distinguished men in his writings, and dis- persed them over all parts of the world.

The illumination of MSS. is generally considered as a corollary to the art of manuscript painting, though, at the revival of painting MSS. were illuminated by painters, the calligraphists must have always been a distinct class, and even the initial letters and borders were executed by distinct personages. The artist who wrote the text often worked from the fact that some MSS. want the initial letters altogether, the spaces being left to be filled in by the proper artist. Though many illuminators of MSS., or miniaturists, at about the time of the revival of painting became especially great painters, it is not likely that painters became the illuminators of MSS. at any time, beyond the execution of the miniatures which were attached to them. There is no moderate- size miniatures as works of art to be found in any MSS., and the best of all are those executed by the celebrated Memling and his nearly contemporary Giulio Clovio, a native of Genoa, called 'il disegnatore di miniatures,' and active before the time when painting was at its highest state of perfection, which shows that the influence of the great works with Flanders and Italy then abounded reached the decoration of MSS. The miniatures of these masters (from minium or oil, red lead, blue, and green) are sometimes said to be the greater; but the reverse was probably never the case, and it would be difficult to show that painting was ever in any way improved or even preserved by the illumination of MSS. The miniatures of the sixteenth and seventeenth centuries are a mere theory founded on assumption. Constantinople always had its painters, and there is a Latin work extant of an early date probably as the ninth century, which treats of painting and illuminating MSS. and miniatures (from minium or oil, red lead, blue, and green) in MSS.

There is a MS. of this work now in the British Museum; it is by Theophilus Presbyter, whom Leonicus supposed to be the same person as Tullio or Tustulo, a monk and painter, 'pictor artifices'; of the convent of St. Gall in Switzerland. The work is printed in Leonicus Beiträge zur Geschichte und Literatur, No. vi., Brunswick, 1781. (Tullo, F. C.)

Vasari, in the Life of Don Lorenzo, evidently informs us that the writers of letters were a distinct class after the revival of painting, for he notices Don Jacopo of Florence, a monk of the convent degli Angeli, of the fourteenth century, as the most of about two hundred, and his work was a sort of self-employment only in Tuscany but in the whole of Europe. He left his convent sixteen folio choral books with miniature illuminations by another monk of the same convent, Don Silvestro, and their skill was 'so marvelling' that his right hand was enameled after their death and preserved in a tabernacle.

It appears that the earliest MSS. of Greek and Roman origin are not much ornamented, their embellishments consisting in little more than the occasional use of red ink for titles or commencementes of books. No ornaments have been found in the Hierotheum papyri. The Egyptian papyri are written in various colours; they contain mythologi- cal figures in red, blue, yellow, green, and white.

The most celebrated collection of Illuminated MSS. is that of the Vatican, already noticed, which, among its 24,000 MSS., contains upwards of fifty valuable MSS. in this collection, and gives specimens of the style of decoration, in design, from most of them. The following are the most remarkable of this collection according to Mr. Shaw ('South Ross, vol. ii. pt. 2, pp. 846-863');—Of the Western or Latin MSS. the earliest is probably the Virgil (Vatican, No. 8216), containing 50 miniatures, 44 of which are from the 13th century, and in many respects an introduction by Sir F. Madden, keeper of the British Museum. There are many papers on this subject in the Academy; and a series of articles on the Progress of the Art of Illumination in the Penny Magazine of 1839.
other accessories are picked out with gold: the date of this MS. is supposed to be not earlier than the fourth century. Among the MSS. are the Historia Sacra (Vatican, No. 453), finished in 1068, and distinguished for its writing, initial letters, and arabesque marginal decorations; it contains only one miniature—the author writing. A still more important copy for its illumination is the Panoplia fortifications against heresies (Vaticana, No. 666), executed by order of the Emperor Alexius Comnenus (1081—1183). In this MS. are three large illustrations on gold ground: two, representing the union of the same leaf—on one the father and the Greek church are bringing the materials of the book, and on the other, the emperor is receiving them; above is an apparition of the figure with the title of benediction—the third illustration, the emperor is presenting the finished work to the Saviour seated on his throne. The figures of these paintings are perhaps the best extant of this or any preceding period; they are about nine inches high, are brilliantly coloured, and the heads have much character: the costume of the emperor is on both occasions very complete; it is quite oriental, and bears no resemblance to the antient costume. (D'Agincourt, p. liii.)

There is also a beautiful MS. of the four gospels, or Evangelium, executed in 1128, in the reign of John Comnenus. The illustrations of this MS. are—Christ seated between Justinian and Theodora, representing the legal code; another with the emperor and the pope, probably Niccolo da Prato, who died at Avignon in 1321 (D'Agincourt, p. lxxii.). No. 1071 of the Palatina is a treatise of the 15th century, on falconry, by the Emperor Frederick. (D'Agincourt, p. 118.) In this period the horses are well executed, but the horses and the human figures, particularly, are bad. (D'Agincourt, p. lxxii.)

The Byzantine MSS., of which there are many in the Vatican, are better illustrated than those of the western empire; their illustrations are strictly in what is called the Byzantine style, but they are often executed with great care, and finished with remarkable detail. No. 1055 Vaticana, is a MS. of the book of Joshua, on a roll of parchment 82 feet long, of the seventh or eighth century. Rumohr (Ital. Forsch., i. 167) is of opinion that these illuminations are copies of earlier works, and that the figures are less well executed, but the horses and the human figures, particularly, are bad. (D'Agincourt, p. lxxii.)

The Byzantine MSS. is also the celebrated Menologium (Vatican, No. 1615), or part of a Greek Calendar, from September to February, with 430 miniatures upon gold grounds, illustrating the life of Christ, and of all the saints whose holidays occur in these months of the year. The miniatures, according to names inscribed upon them, were painted by — Pantaleon, Simeon, Michael Chlachernits, Georwigus, Menas, Simeon Chlachernits, Michael Micros, and Nestor. They are extremely poor in invention, but have considerable merit in the expression of the heads, in the draperies, and detail of execution: the figures in action are the most defective; those in repose are frequently natural. Their manner is generally the subject represented in the life of the saints. There are many characteristic Byzantine buildings introduced in the background. This MS. was executed by the order of the Emperor Basilius I, called Porphyrogenitus in (1059-1067), and is supposed to have been procured from Constantinople by Lodovico Sforza, Duke of Milan. It was presented to Paul V. by Cardinal Sfondrato, and placed in the Vatican Library in 1615. Cardinal Amiconi, Abbot of St. Mary of Vallo, of Cupra, and of St. Andrew in crossing together with a Latin translation, but the engravings of this edition are very inferior to the originals. (D'Agincourt, p. xxiv.—xxv.)

The rest of the Calendar was supplied from a copy of the Library of Grotte Ferrata, in which there are no illustrations.

Plater is of opinion that the best Greek MSS. are those of the period of the Commene emperors (1068-1183), which were illuminated in 1225 by the Crusaders; and particularly during the reigns of Alexius I., Johannes II., and Manuel I., and this opinion is borne out by the illuminations of D'Agincourt. Of these MSS. are the Historia Sacra (Vatican, No. 463), finished in 1068, and distinguished for its writing, initial letters, and arabesque marginal decorations; it contains only one miniature—the author writing. A still more important copy for its illumination is the Panoplia fortifications against heresies (Vaticana, No. 666), executed by order of the Emperor Alexius Comnenus (1081—1183). In this MS. are three large illustrations on gold ground: two, representing the union of the same leaf—on one the father and the Greek church are bringing the materials of the book, and on the other, the emperor is receiving them; above is an apparition of the figure with the title of benediction—the third illustration, the emperor is presenting the finished work to the Saviour seated on his throne. The figures of these paintings are perhaps the best extant of this or any preceding period; they are about nine inches high, are brilliantly coloured, and the heads have much character: the costume of the emperor is on both occasions very complete; it is quite oriental, and bears no resemblance to the antient costume. (D'Agincourt, p. liii.)

There is also a beautiful MS. of the four gospels, or Evangelium, executed in 1128, in the reign of John Comnenus. The illustrations of this MS. are—Christ seated between Justinian and Theodora, representing the legal code; another with the emperor and the pope, probably Niccolo da Prato, who died at Avignon in 1321 (D'Agincourt, p. lxxii.). No. 1071 of the Palatina is a treatise of the 15th century, on falconry, by the Emperor Frederick. (D'Agincourt, p. 118.) In this period the horses are well executed, but the horses and the human figures, particularly, are bad. (D'Agincourt, p. lxxii.)
or Attavante, a celebrated miniature painter, also executed miniatures for Matthiae Corvinus, but Vasari adds that all the MSS. belonging to the Urbinate Library were purchased by Lorenzo de' Medici, and afterwards placed in the Laurentiana at Florence. There is one at the Biblioteca Nazionale which is believed to have been purchased from this source; it was written by the Zenobius Maius in Florence in 1424, and the Codex Medici was probably not the only purchaser of these works. There is an illustrated Dantesque, which has never been published, and it was executed for the duke Federigo, and was presented at the end of the fourteenth century, and it is the last of the series. The manuscript is in the Biblioteca Nazionale at Florence, and the last is that of the death of Dante, and it is the last of the series. The manuscript is in the Biblioteca Nazionale at Florence, and the last is that of the death of Dante, and it is the last of the series. The manuscript is in the Biblioteca Nazionale at Florence, and the last is that of the death of Dante, and it is the last of the series. The manuscript is in the Biblioteca Nazionale at Florence, and the last is that of the death of Dante, and it is the last of the series. 

D'Agnicourt, pl. xlvii.) Of the sixteenth century there are, with the exception of Julio Clovio's and Memling's, scarcely any MSS. worthy of the time, and some of Clovio are injured by their excessive fineness. The miniatures of Clovio have one particular distinction from those of other earlier masters; they are executed in what is at present understood by water-colours, while those of earlier masters are done in body colours, or a species of distemper, a guazzo or a colla; the lights are relieved in white, gold, and silver. The design is both in cases previously put in fine outline. In Chapellin's "Pedia est et Universelle" one of the illustrations of the Order of the Garter in the Vatican is given as Clovio's; it is extremely highly finished. This painter, according to Vasari, spent nine years in painting the twenty-six miniatures in the manuscript of the Virgin (Uffizi, dated 1510), for the Cardinal Alessandro Farnese, now in the Royal Library at Naples. The works of Clovio, however, are not superior, and in some respects are not even equal to those of his predecessor Memling, which are more masculine in their execution. The illuminations of Memling and his scholars are in the opinion of Schorn the finest paintings of their class extent: they are more elegant and more graceful, and when painted in body colours, are quite free from the dark outlines of the Greek and Italian MSS., and have no gold but what is put on with the pencil. The most remarkable work of this class by Memling, in which he was assisted by Gerhard of Ghent and Livin of Antwerp, is the celebrated missal of Cardinal Grimaldi in the Library of St. Mark at Venice (it is described in the Kunstblatt of 1832); Memling died considerably advanced in age in the beginning of the sixteenth century. Memling, P. C. S. There were several good miniatures or miniature painters of earlier centuries, who can be mentioned by name. Oderigi of Gubbio, and his pupil Paolo Bolognese, who are noticed by Dante, are two of the earliest:—

**Memino di Avignon in 1432.** **Menni, Simone, P. C. S.** In the fourteenth century Don Lorenzo and Don Silvestro, already mentioned, Florentine monks, were also celebrated illuminators. Some of the choicest books of Don Silvestro still exist, and are among the best in Italy. Don Bartolomeo and Gherardo, of Florence, already mentioned, died at about the close of the fifteenth century. Francisco Sbar- rione, also of Padua, and his school, were celebrated illuminators. Attavante, their contemporary, is the illuminator of some of the most valuable MSS., in respect of their illuminations, now extant. Vasari attributes to him the MS. of Silius Italicus in the library of St. Mark at Venice, which is one of the finest MSS. belonging formerly to Matthiae Corvinus. In the royal library at Brussels there is a magnificent missal which Attavante illuminated for this king: it has a large folio, and comprises every page of which is decorated with arabesques, flowers, and figures. The miniatures of the two first pages and those at the beginning of the canon mass are, however, by another hand. There is also an ornamental beauty on the first page is written—"Actavantes de Actabantius de Florentia hoe opus illuminavit, a. d. mcccclxxvii. et on other is written—'Actum Florentia, a. d. mcccclxxvii.' The Hungarian scribes are often repeated, but those of Austria and Spain have been since glued over them; there are gold medallion portraits of Corvinus and his queen Beatrice of Aragon towards the end of the volume. The former regents of Belgium used to take their official seal upon this volume: the first to do so were the archduke Albert and Isabella in 1599; and the prince of Saxen-Teschen, in the name of Joseph II., was the last, in 1781. In Italy it was done at the time of Napoleon. In 1796, Charles V.; she obtained the government of the Netherlands after the death of her husband Ludwig II. of Hungary. It is described by Chevalier in the Memoires de l'Academie Royale de Litteratures et Sciences. 

Cosimo Tura, or Cosme da Ferrara, was also a celebrated miniatore of this century, but he was not equal to the Florentines. Liberale da Verona and Girolamo da L'abri were, after Clovio, the most eminent miniaturists in Italy of the sixteenth century. There was an antient geographer of the name of Agatha- dacon, who delineated and illuminated some maps for manuscrits of the Gospels, and in the Dutch MSS. with these coloured maps at Vienna, and another at Venice. Agatha-dacon's time is not known. (Heeren, Commentario de Fontibus Geograph. Photinae, &c.) The ornamental and initial letter decorations of MSS. are almost infinite, and but few of the names of these decorators have been preserved. Some of the arabesque and floral decorations are extremely elaborate and beautiful, and there are also many classes of initial letters which display extraordinary ingenuity, skill, and patience. There are many specimens of initial letters in Shaw's Ornament, &c.; Sir F. Madden, keeper of MSS. in the British Museum, in his Introduction to the Manuscripts of the British Museum, notices the various kinds of letters which prevailed in various times and various countries, and from this the substance of the following remarks are taken. The red ink or minium, cinnabar, was long used very largely, as it was by the Greeks and the early emperors; the popular was the sacred fyraxera, and was at one time used only by the emperor or for his name to imperial rescript, as confirmed by Leo, a. d. 470. This continued until the 15th century. The custom was established in the West by Charles the Bold in the ninth century, but was not continued by his successors. Gold and silver letters were common in the earlier centuries, sometimes written on vellum of a purple or rose colour. Julius Capitulorum, in his Life (c. 4) of the Emperor Maximinus the younger, mentions a present to the emperor from his mother, of the poems of Homer written on purple vellum in gold letters; this was at the beginning of the third century. By the end of the fourth century such MSS. of devotional books became common, but in other classes of literature they were still rare. The Codex Argenteus of Ulfilas, in gold and silver letters on purple vellum, of the year 360, is the most ancient specimen extant of this magnificent description of calligraphy; other early specimens are the book of Genesis in the library at Vienna; the Psalter of St. Germain des Prés; and the fragment of the New Testament in the Cottonian Library in the British Museum (Titus, c. v. x.), all of the fifth and sixth centuries. Eddius, the biographer of Wilfrid, archbishop of York, mentions a copy of the Gospels of this description, which that prelate presented to his church: this was in the year 695, and is the seventh century, and was thus richly executed, as the title. In some Greek MSS. the vellum was burnedished with gold on both sides where it was to be written upon, and was then richly ornamented with coloured arabesques, flowers, and figures. The manuscripts are kept in the British Museum; see Shaw's Illuminated Ornaments, &c., pl. 1-4.
The more beautiful MSS. of the eighth, ninth, and tenth centuries are executed in the gold letter on white vellum. The Harleian copy of the Gospels, No. 2788, and the Bible and Hours of Charles the Bald, at Paris, are among the finest examples of this kind of writing extant. (There are specimens in Prof. Abdy's 'Palaeographia Universalis.') The Charter of King Edgar to the new minister, or Hyde Abbey, at Winchester, in the year 966 (MSS. Cott. Vesp. a. viii.), is the only remarkable instance that occurs of gold writing in England; and a portrait of Edgar between the Virgin and St. Peter. This MS. is much damaged, and the ink has fallen off in many places. In the fourteenth century gold and silver writing became almost universal in manuscripts, with gold and silver along in capitals, the initials were in general not larger than the other letters. The large illuminated initials are said to have commenced first among the Greeks about the close of the seventh century. In subsequent centuries large initials were usual, and they gradually became more complicated and elaborate down to the twelfth century, when they attained such a degree of size, ornament, and intricacy, that they have not in the recent times been surpassed. Those letters are ornamented with all kinds of fanciful figures, composed of men, animals, birds, fish, and flowers. Montfaucon, in his 'Palaeographia,' gives a list of names under which these figures appear, and copies of some of what the Benedictines call, from their illustration of the text, 'Lettres Historiées;' they occur most frequently in Visigothic and Franco-gallic MS. In this alphabet T is represented by a little figure in its mouth horizontally, from the ends of which hang two cocks.

Charlemagne and his grandson Charles the Bald were great patrons of illuminations of MSS. Charlemagne's Bible in the church of St. Paul at Rome was considered by some the best example of ornamental calligraphy extant. There is another very inferior ornamented Bible, which is said to have belonged to Charlemagne, now in the British Museum, but which, according to Sir F. Madden, is of the time of theapsis of the Bald. It is described by Sir F. Madden in the Gentleman's Magazine for 1836; see also Penny Magazine, vol. viii., p. 92, 1839. It was purchased of M. de Speyer-Passavant, who had spent twenty years behind their glasses, and forty years in the collection of such MSS. of the Old Testament, for the comparatively small sum of 750L: he ascertained the trustees of the Museum originally 12,000L. The twelfth century is remarkable, says Sir F. Madden, for profusion of ornament and a greater but intricate mode of illuminating capital letters, which renders it more easy to recognize MSS. of this period than any other. See specimens in Shaw's 'Illuminated Ornaments,' &c., pl. ix. - xii., where there are many varieties of initial letters. The prevailing colours are red, blue, and green, with gold and silver. In the following century red, blue, and white were more common, and frequent yellow and green, which give a less inferior effect: they are mostly German and French. Illuminators were very numerous in the thirteenth century. In the library of Sir Thomas Phillipps, Bart., there is a MS. of this century, entitled 'Laiques,' which is a fine example of small and illuminators. In French and English MSS. of the fourteenth century, initials in purple, red, and gold are very frequent, which contain figures of men and animals, and terminate in spirals, which extend along the upper and lower margins of the page, and support small groups or single figures of dogs, hares, apes, &c. much resembling the decorative stichs and woodcuts which have recently appeared in Germany, and also occasionally in England. A Psalmist of Lord Braybrooke has beautiful examples of this style of decoration (Shaw's 'Illuminated Ornaments,' &c., pl. xii., xiii.).

The History of England, written in the year 1320, and taken continental neighbours. Among the Saxons, at the close of the tenth century, says Sir F. Madden, a peculiar style of ornament prevailed, which, for boldness, correctness of design, and richness of ornament, is worthy of our admiration. This is the character of the so-called 'Vulgate Bible,' and of the manuscripts in the British Museum collection of illuminated MSS.; the latter was given to the Duke of Bedford by Henry VI., at his coronation in France: after passing into various hands, it was several times sold by public auction, and was last bought by Sir John Tolkien in 1849 for 1100L. It is 11 inches high and 7½ wide, and contains 59 illustrations nearly of the size of the page, and about 1000 very small illustrations of borders and foliage, &c.: there is a copy of it in the British Museum. In this MS. is the only known portrait of the Duke of Bedford; the portrait of the duke, engraved by Vertue for the translation of Raphael's 'History of England,' from which the portrait of the duke, in a crimson robe embroidered with gold, is represented kneeling before St. George, who is dressed in a suit of armour, over which is the mantle of the Order of the Garter; behind the saint is his armour-bearer. This MS. was presented by the Duke of Bedford to Henry VI., at his coronation in France: after passing into various hands, it was several times sold by public auction, and was last bought by Sir John Tolkien in 1849 for 1100L. It is 11 inches high and 7½ wide, and contains 59 illustrations nearly of the size of the page, and about 1000 very small illustrations of borders and foliage, &c.: there is a copy of it in the British Museum. In this MS. is the only known portrait of the Duke of Bedford; the portrait of the Duke of Bedford, 118 leaves of vellum, measuring 11½ inches in height, and forming a series of 118 drawings; and it is considered the most valuable MS. of the Cavendish collection. See Mr. Gage's ' Dissertation on the St. Ethelwold Benedictine,' in the 'Archaeologia' (vol. xxiv., p. 224), where the illustrations are engraved. Another curious MS. of this time, now in the British Museum (Cott. MSS., Thib. b. v.), valuable for the pictorial illustrations of old English habits and costume, is a 'Saxon calendar, in which the account of each month is headed by a drawing illustrating the agricultural occupations of the respective months of the year. Julius A. vi. is a fine MS. of the same description. B. iv. is also a remarkable MS. It contains the first six books of the Bible in Saxon and Latin, with notes by Bede and others, and many drawings illustrating the principal passages; it is of the eleventh century. No. 608 of the Harleian MS. contains a long series of illustrations of Anglo-Saxon customs, in very curious designs in outline, executed in various coloured inks; and though the execution is rudimentary, the attitudes and portrayals are well worth consideration.

In the Cott. MSS., Cleopatra c. vii. of the same period there is a comparatively very superior drawing of a party at near drinking together; the poses of the figures are excellent, and the heads and hands are perfectly intelligible and expressive; it is engraved in the Penny Magazine, vol. viii., p. 70, 1839, where there are also a few other cuts from some of these MSS. In the thirteenth and fourteenth centuries Saxon MSS. are comparatively rare: the majority of the MSS. of this period are French.

There is a Psalter in the British Museum, supposed to be of English origin, of a very fine good the representation of some or more probably of the early part of the fourteenth century (Reg. 2 b. vii.), in which the drawing of the period is much better represented than in MSS. generally: some of the illuminations in this volume, containing 390 leaves, are of a very high order; sixty-five are illustrations from the Old Testament, in transparent water-colours, in the usual style of such decorations, the designs being drawn in black outline, and the colours lightly washèd in. This Psalter is followed by drawings of saints in body-colours, which are likewise prepared in black outlines; but in these body-colour drawings the outline is frequently painted over; then follows a Calendar. The greater part of the volume is occupied by the visions described in the 'Vulgate Bible,' and is multiply ornamented with designs, many illuminating the history and habits of the time. This book was presented to Queen Mary in 1553, and is in the library of Lord Willoughby de Broke. There are some French MSS. of the same period in which the illustrations are equally good, as the 'Life of St. Germain des的关系 Le Geste des Roys de France,' both folio volumes, with numerous illustrations. On the last page the words 'C'est livre est a moy Hosmery De Gloucestre de don des executors de sr. De Fauchere.' There is also a French MS., called the Metrical History of the Life of Richard II., preserved in the British Museum, which contains some beautiful illuminations. It is translated in the 'Archaeologia,' vol. xx., by the Rev. John Web. There are three cuts from these MSS. in the volume of the 'Penny Magazine' already quoted.

One of the most interesting French MSS. of the fifteenth century is the celebrated Bedford Missal, executed for John Duke of Bedford and regent of France, in the reign of Henry VI., now in the possession of Sir John Tolkien at Liverpool. It is 11 inches high and 7½ wide, and contains 59 illustrations nearly of the size of the page, and about 1000 very small illustrations of borders and foliage, &c.: there is a copy of it in the British Museum. In this MS. is the only known portrait of the Duke of Bedford; the portrait of the duke, engraved by Vertue for the translation of Bapin's 'History of England,' from which the portrait of the duke, in a crimson robe embroidered with gold, is represented kneeling before St. George, who is dressed in a suit of armour, over which is the mantle of the Order of the Garter; behind the saint is his armour-bearer. This MS. was presented by the Duke of Bedford to Henry VI., at his coronation in France: after passing into various hands, it was several times sold by public auction, and was last bought by Sir John Tolkien in 1849 for 1100L. It is 11 inches high and 7½ wide, and contains 59 illustrations nearly of the size of the page, and about 1000 very small illustrations of borders and foliage, &c.: there is a copy of it in the British Museum. In the Cott. MSS. (MS. 4425), the collection presented by Talbot Earl of Shrewsbury to Margaret of Anjou (Royal MSS., 16 E. vi.), and the poems of Christine de Pisan (Harl. 4431), while the feats of arms and chivalry, by the same author, were des
Fais d'Armes et de Chevalerie," written in French in London in 1434 (Harl. MSS. 4605), is so inferior in its illustrations, that it presents a great contrast between the states of the art of illumination in the sixteenth and the fifteenth centuries. The "Pomme de la Rose" is rich in beautiful miniatures; it is supposed to have been executed towards the close of the fifteenth century; it is a folio volume, measuring 104 inches high by 112 inches wide. The 185 leaves are illuminated and glazed. A single column, the initial letter of every paragraph being illuminated. This French poem is of the sixteenth century; it is a dream, and was commenced by William de Lorris and finished by his companion, de Malus. The work is divided into 100 chapters, and contains 22,000 verses. It has been several times printed, and last at Paris in 1814, in 4 vols. 8vo. The British Museum MS. is considered the most beautiful of the poem extant; the illustrations are probably Flemish. (Dibdin, Bibliographical Decameron.)

The Anglo-Saxons were for many centuries among the best illuminators, and the Irish also obtained great celebrity in this art at an early period. This British or Hiberno-Saxon school of illumination shows a distinct character, as seen from the so-called 'Durham book, or St. Cuthbert's Gospel,' of the beginning of the eighth century, now in the British Museum. The initials, observe Sir F. Madden, are characterized by an extreme intricacy of pattern, interlacing of knots, in a diagonal or square form, sometimes interwoven with animals, and terminating in heads of serpents or birds, to which may be added an 'Airish detached type.' The edges of the larger letters. The Lombardic and Valli-Gothic letters are tessellated and embroidered. There are no British illuminations later than the reign of Henry VII.; and at this time they disappeared.

After the establishment of printing and consequent multiplication of books, MSS. became gradually more rare, though they were still occasionally executed as articles of luxury even as late as the eighteenth century; but their immense price, compared with that of printed books, must naturally have so limited the demand, that they can only have been required as works of art and curiosities in calligraphy, not as books. The writing of many MSS. is so beautifully executed, that probably no movable type has ever equaled the manuscript characters in beauty, and they have perhaps not even been surpassed in equality of execution and finish. See the fac-similes in Sylvester's 'Psalteriographia Universelle.' Perhaps the latest, says Sir F. Madden, or one of the latest illuminated missals, is the immense folio in the library of Rosen, which is nearly three feet high, and cost the monk of St. Andoen, who illuminated it, thirty years of labour: it was completed in 1682.

PALEOAZRA/MIA, a genus of fossil Cycadeid plants, from the oolitic and lias deposits of Yorkshire, Dorsetshire, and Oxfordshire.

PALANQUIN (sometimes written Palankeen, Palanquin, and Pallo), a kind of covered litter carried, by means of poles, upon the shoulders of men, which forms the principal conveyance for the conveyance of state. A very minute description of an ordinary palanquin, together with an amusing account of a dawk or donkey journey, which is the same given to the mode of travelling long distances by the palanquin, is given in the 'Works of the Travelers of the Holy Land,' third series, vol. ii., chap. vi., where the palanquin is described as about six feet long by two and a half feet wide, and provided with conveniences which enable it to serve night-time for a bed, and in the day-time for a parlour. In the front part is usually a broad shelf, with a drawer underneath, and a net stretched above it; and in the hinder part is often a shelf for books, a native of China and other loose articles, and hooks for hats, towels, etc. In each side of the palanquin are two doors, or sliding partitions, with Venetian blinds in the upper panel, and in each end are two small windows. As, owing to the heat of the country, travelling is performed much by night, palanquins are often furnished with a lamp at one corner, so fixed as to throw its light into the interior, but to be trimmed from outside. The bottom, or seat, is made of strips of rattan, like that of a cane-bottomed chair, and is covered with a light elastic material stuffed with horse-hair or shavings produced in dressing the bamboo and rattan. Across the palanquin, at about eighteen inches from the hinder end, is the pole for supporting the bearer's back to receive the weight of the passenger, and below it a broad belt which may be adjusted to the height, or to the length of the passenger's legs, or the choice of position. In the space behind the seat clothes and pillow are stowed away during the day; and the sheets, draperies, and nets afford facilities for the conveyance of baggage, canisters, sharing of seat with the passenger, protection against the materials, and a sufficient supply of clothing to prevent inconvenience if the traveller be separated for a time from his heavy baggage. Flat articles may be laid beneath the mattress, and bottles and glasses may be stowed in the cupboard at the end of the palanquin. A cover of waxed cloth is affixed to the top in such a way that it may be rolled up when not wanted, and let down as completely to envelop the palanquin, in rainy weather. The same is done in the case of the goglet, or gorget, of porous earthenware; and as the water which flows through the pores of the goglet is rapidly evaporated by the current of air, its contents are always kept cool in the hottest weather. The action of this apparatus is identical with that of the alucrazas of Spain, described under Cools, P.C., p. 498. On the hinder pole are carried, in like manner, a kettle, coffee- pot, and wooden wash-hand-basin. As the poles, which rest upon the shoulders of the bearers, are not elastic like those of a sedan-chair, Captain Hall states that a palanquin has not the same unpleasant motion as that vehicle; and Bishop Heber also, who gives an account of dawk travelling in the 'Narrative of A Journey through the Upper Provinces of India,' published in 1824, speaks of the latter as 'a very heavy, whether neither violent nor unpleasant,' but that, being incessant, it is impossible to draw in a palanquin, and not very convenient to read, excepting a large print. In the first edition of this work there is also a general description of dawks, according to which the bearers can, in an ordinary palanquin, place their shoulders beneath the poles, two at each end; but in passing over difficult ground two others will occasionally assist at the back part of the carriage by pressing a bamboo under the body of the quin. In most cases the bearers follow one another in a straight line; but in some districts it is the custom to proceed obliquely, in which case the sideways motion is said to be exceedingly unpleasant to the traveller. While walking or running with their load, the bearers, who form a peculiar caste among the Hindus, keep up an incessant noise, sometimes like grunting or groaning, and sometimes approaching the character of a song, or of wild vociferation. Captain Hall has some curious remarks on this subject.

In the 'Pictorial Bible,' in illustration of a note on Solomon's Song, iii. 9, are representations of the 'J'Alladar, or state palanquin of Hindustan, and also of a similar vehicle used by the ancient Egyptians; and some further information on conveyances of this character is given in the article 'Litter' in the Cyclopaedia of the Holy Land.

PALECHI/NUS, a genus of fossil Echinozoa from the mountain-limestone of Ireland. (Scorler.)

PALESTRA, GIOVANNI PIERLIGI. Da Campra, born at Palestrina, near Rome—the ancient Pristium—in the year 1524, a date which, though with some hesitation for want of direct evidence, has been fixed by the Abbé Bini, who devoted thirty years to collecting material on the history of Palestrina. Of his family nothing is known, except that his parents were mean in rank, and in circumstances corresponding to their station. The name of the master who is entitled to the credit of having instructed him in an art in which he became so famous was involved in some doubt, but after diligent research the honour seems to have been justly awarded to the Claude Goudimel, a native of France, a disciple of the Franco-Belic school, a Hugenot, and one of the victims of religious bigotry in the massacre of 1572, the Catholics on St. Bartholomew's day having thus resented his heresy in setting to music Clement Marot's and Theodore Beza's metrical version of the Psalms.

Palestrina was appointed Master of the Chapel to Pope Julius III. in 1551, to whom in 1554 he dedicated his first work, consisting of four books of Psalm- settings. To reward the composer, placed him among the singers of the Pontifical Chapel, who were well paid for their services. The college of chaplain-singers demonstrated, and pleased the Pope so much that he proposed that Palestrina should be associated with them unless elected by a majority of themselves. But in vain. The mandate of the infallible tiara was obeyed, though not without the kind of vexation that may be sufficient to baffle a man's heart. He proceeded to the papal throne, under the title of Paul IV., who, finding that Palestrina had quitted a state of celibacy, which
all the higher appointments in the apostolic chapel enjoined, abruptly dismissed him, and for some time he felt severely his strained circumstances; then gladly accepted the place of Maestro di Capella of St. John in the Lateran, which he exchanged in 1811 for the lucrative pastorate at Santa Maria Maggiore; and in 1817 was restored to his post in the Vatican. Up to the year 1856 he composed many works for the church, among which Bini, especially mentionous the three Masses, dedicated to himself, was the attempt for a perfect adaptation of music to the sense of the words. 'To hear them as executed on Good Friday in the Sistine Chapel,' says the abbé, 'the mind is subdued by emotions of tender- ness and awe.'

During the above period, however, the Council of Trent, among other matters, took the state of ecclesiastical music into serious consideration, and approved two or three manuals which they charged with its reform, who called to assist them a committee of eight selected from the college of chaplain singers. Much discussion arose out of the case. The cardinals reasonably demanded the abolition of all the secular tunes which had been recklessly foisted into the sacred service, many of them vulgar, some obscene, and required more simplicity in the music. The singers irritatedly defended the melodies, and Bini, who was about to publish a collection of his Masses, urged that Palestrina should write a mass on the principle laid down by their Emminence, and on his success depended the fate, at that time, of music in the Catholic church. In consequence of this discussion, the Council, after some further debate, decided in favor of six voices.

The two first were rather coldly approved, but the third was considered as the perfection of art, and the singers, on whom a ray of common sense had now fallen, could not restrain their expressions of admiration even during its performance. This is known under the title of 'the Mass of Pope Marcellus.' He applied all his powers on the work, and wrought himself up to the most enthusiastic pitch. On his manuscript were found the words 'Domine, Plenitudo sanctorum.' The pope, 'before whom this mass was performed, was enraptured, and compared it to the heavenly melodies which the apostle John heard in his ecstatic trance.' By this one great example the present generation was now for ever set at rest,' says Ranke (in his 'History of the Popes,' acknowledging Bini as his authority); 'a path was opened, in following which the most beautiful, the most touching works, even to those who are not of the church, were produced.'

This art, which had been perhaps more completely alienated from the spirit and service of the church than any other, now became the most closely connected with it. Never before had the church been more spiritual in its sentiment and rapture were the favourite themes of poetry and painting. Music, which speaks a language more direct, more impressive, more adapted to express ideas and emotions, was within the reach of all nations, and thus subjugated all minds to her empire.

The restoration of Palestrina to his office, his fame spread widely, Cardinal Paccecco announced to him that Philip V was disposed of Spoleto. The story is mentioned by the composer that he might dedicate to him. To his other appointment was now added that of Maestro to the congregation of the Oratory. He undertook the direction of the school established by his patron, Gio. Martini. Soon after this he was charged by Pope Gregory XIII. with the task of revising the Roman Gradual and Antiphoner, which, however, he did not live to complete, but performed by his son, now living in Vienna. Rather than to be disappointed, his pen spirituous circumstances must have been much improved, for on his death-bed, after blessing his son, he added, 'I leave my son with God's blessing.'

On the 26th of the following month, after receiving the last rites of the church from the hands of his friend (the future Saint) Filippo di Neri, he expired. Of his funeral, Terriglio (Grotte Vaticane, ii. 166) says, 'In St. Peter's church, near the altar of St. Simon and St. Jude, was interred, in consequence of his similar circumstances, the body of Palestrina, the great musical composer, and Maestro di Capella of this church. His funeral was attended by all the musicians of Rome, and Liberam me, Domine,' as composed by him, was sung. The inscription is,

Johannes Petrus Aloysius Prænestinus, Musæum Princeps.'

Palestrina's music is learned and grave, and it was written for the church—as well, indeed, as much that proceeded from the same school—when heard in the kind of place for which it is adapted, and attended by pomp and pageantry, is strongly felt by all, and acts with irresistible force on sensitive minds. But in the concert-room or chamber, his compositions, whether sacred or secular, have, with few exceptions, no charms for hearers who have not cultivated a taste for simple, solid, airless harmony, or for the intricate and incoherent points well woven with a skill that owed more to study than genius.

His works are exceedingly numerous, chiefly ecclesiastical; but including also many madrigals, now rarely performed, even in societies devoted to this species of music. Choral, as these are, their dryness is undeniable, and they are praised by many who derive no pleasure from their performance. Three of his motets are in use in our cathedrals, adapted by the Bishop of Bath and Wells, the Bishop of Winchester, and Sir C. W. Yonge in his 'Musica Transalpina' (1858), a work containing twenty madrigals by Italian masters; and this is the only published collection of Palestrina noticed in Le Musa Madrigalica (1857); an elegant, interesting volume, comprising the words of 386 compositions, chiefly madrigals, 'of the Elizabethan age,' together with many translations from the Italian, and some English paraphrases. The Padre Martini, in his 'Storia della Musica,' has given two madrigals, and several extracts, from the works of this celebrated master, all of them evincing his deep knowledge of the art, as understood and practised in his time, but all exclusively confined to this style now distinguished by his cognomen—by the term alla Palestrina.'

Within the city of Palestrina, there was a genus of plants belonging to the natural order Cichoracese. The limit of the calyx is 5-toothed or 5 lobed, or nearly entire; the corolla tubular and cyp- tral, and a little wider above; at the base is a ring of hair, bearded beneath the middle inside. The teeth of the calyx and corolla sometimes rather unequal. The species are American shrubs wholly destitute of pubescence. The leaves often curled and of a tint of pale yellow. The pericarp is white in terminal sessile or stalked panicles, thyrse, or cymes. P. Marcipravitii is a shrub from 5 to 6 feet high, and has smooth quadrangular branches. The leaves are short-stalked, oblong, acuminate, obfine at the base, smooth; the stipules interpetalior and tridif. The calyx is 5-toothed and downy; the corolla from 5 to 7 lines long, slightly curved, gibbous at the base, rough downy yellow-coloured below, purplish above, closely bearded with hairs inside. Sometimes the leaves are downy beneath. It is a poisonous plant, used in Brazil to kill rats and mice. Very little is known of its real properties.

P. croceus has a smooth stem, ovate or oval lancesolate leaves acute at the base, rough on the edges, generally three pairs of by the side, linear, acuminate, twice as long as the petiole. The panicle is conical, terminal, and suffrut- cious. The corolla is corymbous and tubular, the anthers projecting from the tube shorter than the limb. The tube someway double. It is a native of Porto Rico, Trinidad, Cuba, and Guad- aloupe. According to Von Martius this species is emetiv.

P. speciosa has a round whitish or pinkish leaves acute at the base, membranous, roughish, shining, with smooth stipules. The panicles are stalked, their angular branches corolla hairy and downy. The leaves have by their yellow, yellowish, sometimes whitish, for the sake of being a shrub, highly spoken of in Brazil as an antispasmodic. 'The decoction, which in large doses forms a real poison, acts especially by an increased action of the skin and kidneys, and the digestion is not injured by moderate doses.'
P. officinalis is a shrub clothed with harsh yellow down in every part. The leaves are narrow, elliptical, short-stalked, acute, or rounded at the apex with a mucronated tapering tip at the base. The flowers are small, greenish yellow, in June. It is native to Europe and Asia, and is used in herbal medicine for various purposes, such as treating stomach complaints and menstrual problems.

P. vulgaris is a shrub with smooth, green leaves and white flowers in June. It is native to Europe and Asia and is used in herbal medicine for various purposes, such as treating stomach complaints and menstrual problems.

The island, the Pico, the Muchachos, which attains 7712 feet, the Pico de Santa Cruz, which is 7549 feet, and the Pico del Cerro, which rises to 7292 feet above the sea-level, are striking features in the southern section. The Pico de Levada, situated nearly in the centre of the island, is 4586 feet above the sea. Towards the southern extremity of the island, there are low mountains, which are called the 'Zarcos', and are formed by deep ravines, called barrancas, whose bottoms are frequently 500 feet below the adjacent ground, and the sides very steep. They are most frequent in the high mountains, and are sculpted by the wind, which blows so powerfully that the sand is swept like rays diverging towards the sea; but they have no communication with the crater, with the exception of the Baranca de Augesta, on the west side of the island, which originates in the crater itself, and is called the 'Baranca de Tazacorte', and in which the only river runs which has water all the year round. It waters the Llano de Llanos, an uneven plain situated on that side of the island which is the best portion of the whole, and at present contains the only plantations of sugar-cane in the Canaries. The sides of the mountains are very steep, and covered with high forest-trees that yield several kinds of good timber. This is especially the case in the northern districts, where the soil retains the moisture, and in these parts springs are frequent and abundant all the year round. In the southern districts the soil consists partly of lava or of other dry volcanic matter, and there are no springs. In these parts the winter is very long and severe, and there is a great degree of fertility; but with the exception of the Llano, the cultivated tracts occur only on the very shores of the sea, or at a few places on the lower terraces of the mountains.

The climate of Palma is superior to that of the other Canaries in its neighbourhood. This is partly attributed to the extent of the mountains, which for several months are covered with snow and wood, which cover a large portion of its surface. The north-east trade-wind, which blows from spring to autumn with considerable force, diminishes the heat, which otherwise would be insupportable along the coast itself. The winter, except in the most elevated parts, is so mild that it is compared with the springs in southern Europe. Earthquakes are not rare, and two volcanic eruptions in the southern districts, in 1566 and in 1678, are recorded.

Palma resembles Teneriffe in its productions. Wheat, barley, rye, and potatoes are cultivated to some extent, and also a small quantity of Indian corn, but the crops are far from being sufficient for the consumption. The deficiency is made up by the root of a kind of fern, called helecho (Plera aquatica), which grows wild on the small hills in the calderas. It is mixed with flour, or even used alone for making bread, which is as black as rye bread, and is said by Von Buch to constitute the principal article of food for two-thirds of the inhabitants. The isle is still grown in the county, and the Llanos, where the crop has been habitually grazed and trampled, the work of Palladus appears to be materially a compilation from previous writers, such as Columella and Martialis Gar- gilius, whose work on agriculture and garden cultivation was lost. The style is inferior to that of Columella, and indicates a late period. The work of Palladus, probably owing in some degree to the convenience of the division, was much used in the middle ages, and the 'Speculum' of Vincent of Beauvais has borrowed much from it.

The population amounted in 1869 to 28,878 individuals, but MacGregor states it in 1830 to have increased to 33,000. The people are descendants of Spaniards, who settled there at the time of the conquest, and of a few Flemish families. They are remarkable for the oddity of their language, consisting of sugar, almonds, fruits, deals and timber, pitch, charcoal, raw and manufactured silk, brandy, and orchilla. They import European goods, oil, grain, potatoes, salt-fish and flour.
P. frutescens is also used in China and Cochín-China as a febrifuge, and as an astringent tonic. It has a shrubby unarmed stem, pinnately decomposed leaves; petiole oval oblong leaflets eburneously and dentately serrated, the ultimate ones deeply trillate and narrowed into a petiole. The flowers are umbelliferous at the apex. It is a native of the islands of Ternate, Java, and Amboyna.

The hardy species of this genus grow best in pots, and are propagated by the ordinary methods, or by cuttings of the rooted portion of the reseeds. They are grown in a mixture of loam and sand, and are propagated by cuttings, which should be planted in sand with a hand-glass over them.

(Don's Gardener's Dictionary; Lindley's Flora Medica; Garrett's Outlines of Horticulture.)

PANVINIO, ONUFRIIO, was born at Verona in 1529. He took an early age the habit of the order of St. Augustin, and pursued studies at Rome, where he was called to Florence in 1544 to fill the chair of theology in that city; but soon afterwards, at his own request, was superceded in the office, and obtained leaves from his superiors to visit the chief cities of Italy in order to collect inscriptions. At Venice he became acquainted with Sigonio, who had been appointed professor of belles lettres in that city in 1559, and who was not less enthusiastically attached than Panvinio himself to the study of antiquities. The acquaintance soon ripened into a lasting friendship. At Rome he was patronised by Cardinal Cervini, who in 1555 became Pope Marcellus II., and by him Panvinio was appointed to a situation in the library of the Gregorian college. The pope however died a short time after his election; and Panvinio was then patronised by Cardinal Farnese, who gave him apartments in his palace, admitted him to his library, and treated him with the greatest liberality. Having accompanied the Cardinal in a voyage to Sicily, he was taken ill at Palermo, and died there April 7, 1658, at the age of thirty-nine.

Panvinio was a man of great learning and indefatigable industry. Niceres, in his 'Mémoires,' mentions twenty-seven of his works which had been printed; and Maffei, in his 'Verona Illustrata,' gives a list of his manuscripts in different libraries of Italy and abroad. The chief of these are the following, some of which were not printed till after his death:—Epitome Pontificum Romanorum usque ad Paulum IV.; Venice, fol., 1557; Viginti-septim Pontificum Romanorum Elogia et Imagines, Rome, fol., 1568; Pasti et Triumphi Romanorum a Romulo usque ad Carolum V.; Venice, 1557, of which Mader published another edition in 1662 at Helmstatt; In Fastos Consularum Appendix; De Ludis Secularibus et Antiquis Romanis; et al. De Antiquitate et Virtu Illustrissimae Veronae Libri VIII.; Padua, fol., 1648. The following treatises are contained in the great collection of Graevius, 'Thesaurus Antiquitatum Romanarum':—De Civitate Romana; De Imperio Romanis; in vol. i.; De Antiquis Romanorum Nominius; in vol. ii.; 'Antique Ursis Imagin'; in vol. iii.; 'De Ludis Circensibus,' 'De Ludis Sacrisculibus,' and 'De Triumphi Commentarius,' in vol. IX. His great treatise 'De Cerimonibus Romanis' was published in four folio volumes, in 1568; the first three were issued at Venice, the fourth (consigned to Dornus, his publisher) in the arrangement of Boisduval, and Dornus in that of Latrelle, corresponds with the Linnaeus genus Populorum. The insects composing it have mostly thin and elongated integuments, terminate beyond the claws, and the male abdominal segments are usually variously shaped, have six pectoral, eight abdominal, and two anal teeth. The pupa are usually angulated and, with a few exceptions, naked. The perfect
insect varies in size from less than an inch across the wings when expanded, to nearly a foot in breadth. Equally variable are their colouring and outlines. They are short-lived. There are very great differences in the mode of flight which varies in the several species. The males are usually more gaily coloured than the females.

The arrangement according to natural relations of the species of butterflies has been attempted by many naturalists. Even in the time of Linnaeus the number and variety of known species was such as to render it necessary to subdivide his great genus Papilio. He constituted five principal groups. In the first of these, named Eupides, he included such butterflies as have the fore wings longer from the posterior angle to the apex than to the base. In the second, the Heliconii, the wings are narrow, entire, and often almost naked. The Danaius has the entire wing margins. The nymphalides have the marginal wings; and the group of Plebeii was composed of small species, whose larvae are usually short and thick.

Dr. Horsfield has proposed an arrangement of these insects into five groups or tribes, characterised by the peculiarities of the larvae. He names the first stirs, Vermiformis, the second Jufiform, the third Scopendris, the fourth Thy amoniform, and the fifth Anaplariform.

Perhaps the most valuable arrangement of the diurnal Lepidoptera is that proposed by M. Boisduval, who divides them into three great sections and fifteen tribes, as follows, founding his classification upon the characters of the larvae:

Chrysalis attached by the tail, and also gilt.

A. Six feet in both sexes: caterpillars elongated.
   Tribe 1. Papilionides.
   Tribe 6. Paraidades.

B. Six feet in both sexes: caterpillars short.
   Tribe 3. Eumenides.
   Tribe 4. Lecydonides.

C. The males with four feet, the females with six: Caterpillars short.
   Tribe 5. Erycides.

D. Four feet in both sexes: caterpillars elongated.

E. Chrysalis suspended by the tail only.
   A. Ungues of tarsus simple. Four feet in both sexes.
      Tribe 7. Danaides.

B. Ungues of tarsus strongly bifid. Four feet in both sexes.
   Tribe 11. Morphides.

C. The males with four feet, the females with six: Caterpillars elongated.

Chrysalis enclosed in a cocoon.

Tribe 15. Harpoides.

See Boisduval in the Species et Effets and his other works: Wood, Index Entomologicus; Horsfield, Catalogue of Lepidoptera in the Museum of the East India Company; and Westwood's Modern Classification of Insects, where an enumeration of the principal treatises on butterflies may be found.

PAPIRUS, SEXTUS or PUBLIUS, is the collector or supposed collector of the old Leges Carinates, or as they are sometimes called, Leges Regiae, which were enacted at Rome during the kings of Rome. This Papiorius is said to have been Pontius Maximus and to have lived under the last Tarquin. The few and doubtful fragments of this supposed compilation are contained in Hoffmann, Hist. Juris, vol. ii. p. i. The collection is mentioned under the name of Jus Papirium, not because he added anything of his own, but because he arranged the laws in due order (Pomponius, Dig. 1, tit 2, s. 2, 1, 2); and sometimes it is called Lex Papiria. (Servius ad Virg. Aenid, xii. 886.)

PAPIRUS, JUSTUS, a Roman jurist, who compiled twenty books of Constitutions, according to the Florentine Index. There are sixteen excerpts from this work in the Digest. In one excerpt (Dig. 2, tit. 14, s. 59) Papirius mentions a rescript of the Emperor Antoninus, addressed to Avidius Cassius. The fact of the rescript being addressed to Cassius shows that Antoninus is the Emperor Marcus Aneto-

In PAPARINTUS. Accordingly Papius was living under Marcus Antoninus; and he also survived him, as appears from his speaking of the Divi Fratres. A jurist of that name, from the mode of flight which varies in the several species. The males are usually more gaily coloured than the females.

area from the dispersion of the stones when shot or shells are fired into the mass; and the slopes, as well as the banquettes, are usually covered with turf.

Paraseleæ (from σάρκα and σαλαμάς the moon). This name is given to the ill-defined and faintly luminous disc, apparently round, but surrounded by the moon, as the corresponding but brighter spots which are seen in halos about the sun are called parhelia. [HALO, P. C. S.] The phenomena of paracelsus and paraseleæ are ascribed to a like cause; that is, a blending of the rays of light reflected from the parallel sides of small triangular plates of ice with those which are refracted through the sides containing one of the angles.

One of the earliest recorded phenomena of this kind is that which was observed by Hevelius at Danzig in 1660: a double halo surrounded the moon, with coloured segments nearly resembling those which are represented in the second figure in the article above referred to; and in the inner circle at each extremity of a horizontal diameter was a false moon: it was faintly tinged with colour and, at intervals, beams of whitish light proceeded from it towards the exterior.

Sir Edward Parry, during his voyage to Melville Island, saw several lunar halos with paracelsus; and, once, very nearly the like phenomena occurred on two successive nights. The observer, in the articles above, directed to discover the omens of a horizontal diameter, and one at the upper extremity of a vertical diameter; while from the real moon proceeded vertical and horizontal brushes of whitish light like the four arms of a cross. On one of the four extremities of light issued from the eastern moon, like part of a second halo, and at times ascending almost directly towards the zenith. Another time the moon was surrounded by a double halo, and on the circumference of the inner circle appeared a double paracelsus, at the opposite extremities of a vertical and a horizontal diameter.

Parent-Duchâtelet, ALEXANDRE-JEAN-
BAPTISTE, was born at Paris on the 28th of September, 1790. His father held an office under government which had been in the family for upwards of three centuries. At the birth of Alexandre he was possessed of considerable wealth, and his father had already seriously affected his circumstances, and he retired to a house in the country called Châtelet, about a league from Montargis. Here Alexandre, who was the eldest of five, was brought up with little further assistance in his education than could be given by his mother, who was an amiable and accomplished woman. He was, however, fond of study, and early exhibited a taste for natural history by collecting the insects and birds of the neighbourhood.

At the age of seventeen he was sent to Paris, where he commenced the study of medicine. In 1814 he took the degree of doctor of medicine at the University of Paris. He became early dissatisfied with the practice of medicine, and directed his attention to pathology. One of the earliest works which he published was upon inflammation of the lungs. This was published in 1816 by M. Martinet; the title is "Recherches sur l'inflammation de l'arachnoïde cérébrale et spinale, ou Histoire thêorique et pratique de l'arachnitis," Paris, 1821. This work is a valuable monograph. The mind of the author was however shortly after directed, through the influence of Hallâ, to the subject of public health, and from the period that he first thought upon this subject to the day of his death, he devoted all the energies of his mind to it. From 1821 to 1836 he published twenty-nine memoirs and papers on various questions relating to public health. One of his first efforts on this subject was a series of papers on the different causes of a disease which had occurred on board a vessel which was conveying poudrette across the seas. Parent examined the manufacture of this substance, which consists of animal and vegetable matters which have been collected from the drains and sewers of Paris, and, being exposed to the sun and air, are allowed to dry. In this state it is used as a manure. It was the fermentation of this substance, its conjunction with moisture, that had produced the disease, and Parent recommended that in future plasters of Paris should be mixed with it, which prevented the recurrence of such catastrophes.

His next work was on the common sewers of Paris, entitled "Essai sur les Cloaques ou Égouts de la Ville de Paris, envisagés sous le Rappor de l'Hygiène Publique et de la Topographie Médicale de cette Ville," Paris, 1828. Parent-Duchâtelet here displayed the peculiar acuteness of his mind for the investigation of subjects which others regard with natural abhorrence. He not only made inquiries into the state of the health of the workmen employed in cleansing these places, and obtained from them much important information, but he entered with them the places of their noseless and illogical congeners, and, in various reports, reported on their condition and nature. Shortly after the publication of this work, Parent was appointed on a commission to superintend the emptying of one of these sewers (égouts) which had been blocked up for years, and which threatened to generate fever of the worst kind. Under his direction this place was cleansed without the loss of life to a single workman, and without any evil results.

He subsequently contributed largely to the Annals of Hygiène Publique et de Médicine Légale. In this work he will be found reports and papers by him on the influence on the health of workmen and the public, of tobacco manufactories, of pyroxyline-acid factories, of employments requiring immersion of the feet in cold water; of burying the dead in cities; of putrid emanations from dead animals and vegetables, of dissecting-rooms, &c. He also published a work on the progress of cholera, and a history of its ravages in Paris. His greatest work, and that which most displays the industry and character of the man, is that on prostitution in the city of Paris which he published in 1839, and which he wrote, not with the title 'De la Prostitution dans la Ville de Paris considérée sous le Rapport de l'Hygiène Publique, de la Morale, et de l'Administration,' Paris, 2 tomes. 8vo. 1836.

Parent-Duchâtelet died of inflammation of the lungs, on the 7th of March, 1836. Few men have led a life of greater usefulness, and his labours have assisted in laying the founda-

PAREXUS, a genus of Placoid fossil fishes, from the old red-sandstone of Scotland. (Agassiz.)

PARIETARIA, a genus of plants belonging to the natural order Umbellifera, and having a numerous number of flowers. The flowers are dry and of a fibrous style. One species, P. officinalis, Wall. The flowers, leaf, or chlorella ovate leaves, without lateral ribs at the base, two axillary biform cymes, the segments of the involucre ovate obtuse. The leaves are alternate, the flowers small and reddish, the fruit black and shining. It is a British plant, and is found on old wall and rubbish. It is the P. eucuma of Koch and Reichenbach.

(Babington's Manual of British Botany.

Parent-Duchâtelet.

PARIS, a genus of plants belonging to the natural order Asparagaceae. It has a patent horizontal perianth, 8-parted to the base, the four inner petals or corolla narrower than the others. There are 8 stamens, the flowers fixed to the middle of a column, and antheroid filaments. The styles are 4 in number, the berry 4-celled, the cells from 4 to 8 seeds."

P. quadrifolia, Herb París, the only British species, has usually 4 leaves in a whorl, a stem about a foot high springing from the extremity of a long rhizome usually with 4, occasionally from 3 to 6 leaves at its summit. The flowers are solitary and terminal, the sepals lanceolate, the petals subulate. It has no root-leaves and is found in damp woods in England. It is considered to be a narcotic-acid poison.

P. polyphyla, a native of Nepal, possesses similar properties and effects. (Babington's Manual of British Botany; Burnett, Outline of Botany; Lindley's Vegetable Kingdom.)

PARMELIA. (Lavrenvorts, P. C. S.)

PARNASSIA (from the name of Mount Parnassus), a genus of plants belonging to the natural order Droséeraceae. It has a 5-cleft deeply-cleft calyx, 5 petals and 5 stamens, with 5 scales fringed with glandular seta inserted. The stigma is septic and 4 in number, the capsules 1-celled with 4 valves. The species are smooth herbs. The leaves ovate, cordate, cordate, usually clasping the stem or leafy. The flowers are all white striped with green; the seed of the glands.

P. palmata, Marsh or common Grass of Parnassus, has cordate stalked radical leaves, the stem-leaves amplexicaule, the filaments of the petaloid scales from 2 to 18; the petal has a short claw, and is white and veined; the glands of the
PAR

408

PAS

scales yellow. It is native throughout Europe, in marshy and damp
places, and in Britain in moist mountains. *P. fimbriata* is a very
elegant species; the leaves are remarkably hollowed out at the base
close to the lateral ribs, which are connected with one another by a
common base like the 'tendril leaf.' It has a fine tuft of
branched, glandless, pendulous, oblong petals fringed at the base.
It is native of the western coast of North America.

The species of this beautiful genus grow best in a peat soil and
convenience. They must be grown in pots, which should be placed
in pans of water. They may be propagated by dividing at the
root, or by seeds, which ripen in plenty. Plants must be introduced,
as seeds do not vegetate after a season of rest.

(Don’s Gardener’s Dictionary; Babington, *Manual of
British Botany*).

PARNY, EVARISTE DESIRE DESFORGES, Chavaller and afterwards Vicomte De Parny, was born in the Isle of Bourbon, on the 6th of February, 1753. At the age of nine he was sent to France and placed at the College of Rennes; but he appears to have shown considerable indif-
ference to the course of studies which were followed there.

His imagination, which even at an early age had taken the
almost entire guidance of his conduct, impressed him as he
grew up with the belief that he was made up to enhance the
terrible effects of his genius; it is said that he attempted to
join the brotherhood of La Trappe. An effort of improp-
der zeal, however, on the part of the confessor whom he had
called his spiritual guide, produced a rapid change in the
mind of the young convert, and he is related to have fallen into
an opposite extreme of conduct, and soon after, entering into
dislavours, finally to have enrolled himself as a painter of
paints. He returned to his native island at the age of twenty, when he became acquainted with a young creole lady, the Eleanor of his verse, which
acquaintance his fervent affection soon converted into the
most ardent attachment. Their mutual love inspired his first
poetical effusions, which paint with grace and freshness,
though perhaps in too vivid colours, the all-absorbing passion
of his soul. The affections however of the lady were of an
exquisite sweetness and a refined delicacy, which she intro-
ducted at the desire of her parents, induced Parny to return
to France. Distance and time were unable to efface his sad
reminiscences, and he there continued to translate into the
languages of poetry the feelings which appear to have taken
a lasting possession of his mind. In 1775 was published his
first collection of elegiac poems, which have been so much ad-
mired by his countrymen that they have earned for him the
title of the French Tibullus. On the breaking out of the
French Revolution he became deprived of the property which
he had inherited from his father, and he was compelled to ob-
tain a livelihood by the cultivation of his talents, and now
appears in many writings, which he had the weakness to adapt to the prevalent taste of a corrupt
tide. The rival of Tibullus became the feele copyist of
*Vesuvius, et les Bergeries de la Brie,* and *Guerre Des Dieux,* by their disgusting profaneness and
absence of genuine poetical feeling, will only be remembered
by posterity as indications of the state of society at a period
when everything evil was rank and luxurious. So strong
indeed was the feeling excited against Parny even in France
on account of the last mentioned of these three poems, that
his name was repeatedly passed over among the candidates for
the honours of the Institute. However he was admitted into
it in 1803, in the place of Devaines. Most of his other
poems are inferior to his early productions; his *Goddam,*
published in 1804, is a spiritless and insipid parody on the
invasion of England by the Normans; his *Isle de
Aglaia,* though possessed of more merit, is but a feeble
imitation of the Scandinavian style of poetry; but among his
later productions there are two small poems, one on the
culture of flowers, and the other entitled *Journal Champˆ
tre,* which for simple beauty and delicacy of colouring are
deserving of being ranked among the finest specimens of lyric
poetry. His principal poem, in eight cantos on the love of
Dece, was described by him from fear of its falling into the hands of the suspicious judges of the Revolu-
tionary Tribunal. He died in Paris, after a painful and
lingering illness in December, 1837.

His works have been published in 6 vols. 18mo. by Didot,
Paris, 1808, and at Brussels, in 2 vols. 8vo. The best
edition, however, is that by Mona Boissoneau in the *C
ollection de Classiques Francais,* Lefevre, Paris, 1827. A

volume was published in 1826 entitled *Le Poëtes inédi
fête,* with a notice on his life and writings by Mons. Tissot.

PAROCHIAL REGISTERS. [REGISTRATION OF
BISHOPS; S. P. C. 8.] [PARNABYUM; P. C. S.]

PARIS.

PARTNERSHIP. In 1857 a statute was passed (7 Wms. IV.
& Vict. c. 73) authorizing the crown, after a reference of an
application to the Board of Trade, to grant a species of incorpo-
ration to binding partners under the privy seal. The patent may limit the responsibility of partners to a
certain sum per share. The company obtaining such a privi-
lege must be constituted by deed of partnership, containing
its name, objects, the place where its business is to be
conducted, the names of the members, and the appointment of
two officers in whose name the company may sue and be sued.

These matters must also be entered, along with the additions
of the members and the shares held by each, in a numerical
order in a return which must be made within three months
after the date of the patent—in England or Ireland, to the
Enrollment Office of Chancery; in Scotland, to the General
Register House. Notice of the execution of the partnership
must be sent within three months. This registration is the criterion both of
benefits and responsibilities: no one is entitled to profits
unless as owner to registered shares, and no one is relieved
from responsibility until his name is entered in the regis-
ter. The extent to which this statute may have been adopted
in practice is not publicly known.

PASSABALDON, a genus of fossil Placoid fishes, from the
Bagash sand. (Buckland.)

PASSENGERS. [Smith, P. C. S.] MEYER, PHILIP.
ADAM, A distinguished painter, and author of one of the best collections of
biographies of Italian artists, was born at Rome about the year 1610 or
earlier. Passeri received a good education, and, according to his own account,
did not take up painting until comparatively late; he was first engaged in the
tapistry of a painter in 1656 by Canini in the Villa Aldobrandini at Frascati,
where he contracted an intimate friendship with Domenichino, then returning
from his travels in Italy. Canini was so well pleased with him that in 1641, Passeri was president of the Academy of St. Luke, and he read a funeral
oration on him, and painted a portrait of him, which was placed in the academy with other portraits
of painters, which are at present in the gallery degli Uffizi at Florence; the portraits now in the academy at Rome are
copies. (Platner, *Beschreibung der Stadt Rom.*) At the close of his life Passeri entered into holy orders; and in 1675 obtained a benefice in the college of Santa Maria in
Visa Letia. He died in 1679.

Passeri is one of the best of the Italian historians of art; his his-
thetic description was greatly admired, and was supposed to be very correct.
The circumstance of his book lying for nearly a century unnoticed, or rather unpublished, was owing to
its unfinished state and the severity of many of his remarks, especially those on the works of Domenichino.
He died in 1679, and his last five lives, as follow: Domenichino, Baccio
Ciarpi, Pieter Leur, called Bamboeck, Guido, Il Fiammingo, Agostino Tami,
Francesco Mocchi, Lanfranco, Camassei, Gabinista Can-
ziarda, Vinci, Alzamassa, Alessandro Turco, Pietro Testa,
A Caroselli, Aluardi, G. Rinaldi, G. Miele, M. Langhi,
G. U. Abatini, Luigi Gentile, Giovanni Finelli, Ag. Metelli,
Albani, M. Cervonzzi, Catterina Ginnali, Andrea Sacchi,
Romancelli, Gin. Freroni, N. Pousami, N. Baratte,
Gio. Ang. Canini, Guercino, F. Boromino, P. F. Mola,
Pietro da Cortona, e Salvador Ros.

There is a fine public picture by Passeri in Rome, a crucifixion between two saints, in the church of San Giovanni
della Malva. They are not so rare in galleries. He painted
sometimes still-life. His nephew Giuseppe Passeri was
likewise a pupil of his, and was not less esteemed. He

PASSANO/NO, DOMENICO DA, or DOMENICO CANARI, Cavaliere, was born at Florence about the middle of
the sixteenth century. Some accounts give 1560, but this is
probably too late; Begliosi says he was eighty years old.
when he died in 1658, which would place his birth in 1657 or 1658. He was the pupil of Federigo Zocchi, and lived some time in Venice, where he acquired a great preference for the Venetian school of painting, and especially the works of Paolo Veronese. He was then employed by the popes Paul V. and Urban VIII.; he painted the Crucifixion of St. Peter for the Capella Clementina in the great church of St. Peter on the Vatican, for which work he was paid 200 scudi. On the death of the painter Guercino, he spent the latter part of his life at Florence, and he was one of the most influential of those painters who contributed towards the reform of the Florentine school by improving the taste for landscape painting. His pictures of the Venetian school were popular. Passignano was the friend and associate of Cigoli, and is said to have been the master of Lodovico Carracci while in Florence. He died in 1658. He had many scholars, of whom Luca della Penna was the most distinguished.

(Baglione, Vite dei Pittori, &c.; Lanzi, Storia Pitztorica.)

PASTINACA (from pastinum, the Latin name for a two-pronged fork), a genus of plants belonging to the natural order Umbelliferae, and the tribe Pseudeceandria. It has a calyx with 5 very small or nearly obsolete teeth; round entire petals, involute, with an acute point. The fruit has a dilated flat margin. The carpels with slender ridges, 5 dorsal equilateral, two lateral distant, near the outer edge of the dilated margin. The interfascicles with single linear vitre.

P. sativa, Parsnip, has an angular furrowed stem, pilose leaves, downy beneath, ovate oblong, acute, crenate, serrate, often with a false petiole. The stem is 2 to 3 feet high. The flowers are yellow. The leaves generally shining above, sometimes downy beneath. It is native of Great Britain and America. It is found in the hill-locks, and on a chalky soil. The root is spindle-shaped, white, aromatic, mucilaginous, and has a sweet taste. A variety of this species, P. edulis, is the common edible parsnip, and is much cultivated in our gardens. For cultivation and uses of this variety see article Parsnip, P. C. Another variety, called P. Coquincis, has roots from three to four feet long, and upwards of six inches circumference. It is extensively used in the kitchen of Germany as fodder for cattle. In the north of Ireland parsnips are used in the composition of a kind of beer brewed with hops. Wine and spirits are likewise made from the roots.

P. Secale is another edible species of this genus, and is native of Syria and Egypt. It has a grey root, a terete downy branched stem, pilose downy leaves, pinnatifid cut leaflets, blunt and unequally toothed. It is cultivated in the Levant, under the name of Sekadul. The species are only to be increased by seed, which should be sown in the open border early in the spring.

(Don's Gardener's Dictionary; Babington's Manual of Herbs.)

PASTURE, COMMON OF. [COMMONS, P. C.]

PATELLOIDEA, a genus of molluscs proposed by MM. Quoy and Gaimard for certain Gastropoda, which have shells open below, similar to those of the genus Patella. The shells are cervico-branched. It is synonymous with the genus Lottia of J. E. Gray. The Patella testudinaria of Fabrictius, a shell not uncommon on the northern coasts of Britain, is the type. Numerous species are known, inhabiting all latitudes and living in various depths of water. Their shells are gaily coloured, often tessellated and rayed with purple, orange, or pink. The animals are usually of a uniform tint of white, orange, or pale red.

PATENT. The 7 & 8 Vict. c. 69, § 2, enables a patentee, by petition to the Queen in council, to obtain an extension of the patent term for any time not exceeding fourteen years. 'Some patents took their time at the expiration of seven years, is now granted under the powers of the said act of his late Majesty (5 & 6 Wm. IV. c. 83). This act of Victoria contains also a provision applicable to the patent acts of the time in force, that no new letters-patent which may have been granted under 5 & 6 Wm. IV. c. 83, to an assignee or assigns, and declares that such new letters-patent shall be as valid as if they had been made by virtue of the patent so granted; and not withstanding that this act contained shall give validity to any letters-patent hereafter granted to an assignee or assignees, when any action or proceeding in Scire faciunt or suit in equity shall have been commenced before the passing of this act, wherein the validity of such letters-patent shall have been or may be questioned.

PATENT. [PARTNERSHIP, P. C. S.]

PATERNITY, WILLIAM. Of the early history of this man, who originated several celebrated projects, little is known. By some accounts he is said to have been brought up to the clerical profession; by others he has been said to have migrated to the West Indies, and to have subsequently become a buccaneer. In the account however of the parish of Tinwald, Dumfries-shire, in the first volume of the statistical account of Scotland, it is stated that he was living there in 1718, and that his name is mentioned in that parish about the year 1660, that he was respectably connected, and that he more once sat for Dumfries-shire in the parliament of Scotland. Whatever may be his early history, he must have had ample opportunities for a self-acquainted with the commerce and institutions of foreign countries, and he was probably an extensive traveller. His schemes regarding banking and trading projects are said to have been first offered to the mercantile communities in the Low Countries, and to have been coldly received. He subsequently laid his plans before the merchants of London, and it seems to be nowhere doubted that they were the foundation of the project of the Bank of England, incorporated in 1694. [BANK, P. C.] From the rapidity with which the scheme was brought into a working shape, it may be conjectured that very little alteration was made on the original suggestions of Paterson. It does not appear clear that the inventor was for any length of time practically connected with the working of the institution. It is usually said that the rich capitalists, once possessed of his ideas, quarrelled with him, set him adrift, and drove a project which had the advantage of the public with active and enterprising spirits, who, by the two kingdoms being under one crown, had lost much of that department of foreign service which their ancestors had held in states at war with England. There was an earnest desire to rival England in commerce and manufactures, and in colonies, of which Scotland was not previously possessed. An act of the Scottish parliament was passed on 26th June, 1695, incorporating certain persons by name, with powers to add to their number, to be called 'The Company of Scotland trading to Africa and the Indies.' Very important privileges, both in connection with foreign trade and with the incentives to the commerce of the company, were granted to the members. The company raised a large subscription in England. Its progress roused the English jealousy of trade, and after some representations by the East India Company and other bodies of traders, a petition was presented to King William, in which they stated, 'that by reason of the superior advantages granted to the Scottish East India Company, and the duties imposed upon the Indian trade in England, a great part of the stock and shipping of this nation would be carried thither, by which means Scotland would be rendered a free port, and Europe from thence supplied with the products of the East much cheaper than through them, and thus a great article in the balance of foreign commerce would be lost to England, to the prejudice of the national navigation and the royal revenue.' In fact, under the guise of a company having a monopoly, Paterson's plan would have developed itself to the extent of establishing itself, as a nucleus of free trade; and its opponents rather felt how unable they would be to compete with this untrammelled community, than saw in its constitution any general principle of superiority to the restrictive measures put in force by the powers they were connected. 'We do hereby publish and declare,' says the first proclamation of the company, 'that all manner of persons, of what nation or people soever, are and shall be from henceforward to be excluded, equally as free men, from all said properties, privileges, protections, and immunities, and rights of government granted unto us; and the merchants and merchant-ships of all nations may freely come to and trade with us without restraint, proviso we do not take part in the manner of capture, confiscation, seizure, forfeiture, attachment, arrest, restraint, or prohibition, for or by reason of any embargo, breach of the peace, letter of marque, or reprisal,
declaration of war with any foreign prince, potentate, or state, or upon any other account or pretence whatsoever. And we hereby not only grant, concede, and declare a general and equal freedom of trade, navigation, and commerce to the commerce of all nations who shall hereafter be of or concerned with us, but also a full and free liberty of conscience in matters of religion.' In contemplation of a company carried on such principles as the English Parliament intended to establish, King William issued a proclamation to the effect that 'the privileges granted their company would render their country the general storehouse for tobacco, sugar, cotton, hides, and timber; the low rates at which the English manufacturers might be paid would enable them to undersell the English in the competition with them.' King William was induced to discountenance the undertaking, and the projectors were deprived of all aid, not only from England, but from foreign nations also. This was the more truly national object, and all the disposable wealth of Scotland was speedily embarked in it. The main scheme of the company was to establish a colony at Darien, when Paterson believed that it would be in the middle of the highway of the world, and form the emporium where the commerce of the East would meet that of the West. With all due respect for the principles on which the commerce was to be conducted, it may be questioned if the possession possessed all the peculiar advantages which it attributed to it, especially at a time when regular commercial enterprise had made so comparatively little progress. For this reason, on the 5th of July, 1698; its disastrous results may be found recorded in the ordinary histories of the period, and particularly in Sir John Dalrymple's Memoirs. Paterson was ambitious, but not mercenary. It may be said of him that he had reaped only of the profits which those confident of its success had assigned to him. The failure of the expedition preyed deeply on his spirits, and grief and disappointment brought him, during his return home, to the borders of lunacy. He lived subsequently a life of obscurity, and the period of his death is not recorded.

PATRIARCHS. We propose to give a chronological list of the Patriarchs of Alexandria, Antioch, Constantinople, and Jerusalem, arranged systematically with the Reformation Popes, for which reason we place the article under Roman Church.

PAVONA (in honour of Don Joseph Pavon, M.D., of Madrid, a traveller in Peru, and one of the authors of Flora Peruana). A genus of plants belonging to the natural order Malva. It has a 5-cleft persistent calyx, surrounded by an involucre from 5 to 15 leaves. The ovary has 5, and rarely 4, 1-ovuled cells. It has 10 stigmas, 5 carpels, capsular, 2-valved, and 1-seeded.

P. diuretica has coriaceous acuminate serrated leaves, velvety on both sides, and full of pellucid dots. The flowers are white, and sulphur-coloured. It is native of Brazil, in the province of Minas Geraes. A decoction of this plant is used in Brazil as a diuretic. This is the only species of Pavonia used in medicine; many others are however well known for their beauty of form and of colour. They are all free-growing plants, for the most part ripening seed in abundance, and cuttings will root freely under a hand-glass.

(Don's Gardner's Dictionary; Lindley's Flora British.)

PETICHETA (from the Latin word pediculus, a louse, from its supposed quality of making sheep that feed upon it lousy), a genus of plants belonging to the natural order Scrophulariaceae. It has an inflated 6-toothed calyx, a ringed corolla, with the upper lip laterally compressed, the lower lip 3 lobed. The capsules are acute, and compressed. The seeds numerous and angular. The species are usually simple herbs. The flowers sessile, disposed in dense terminal interrupted spikes.

P. pubescens has a solitary erect stem, branched throughout, pinnatifid leaves, with oblong blunt lobed segments; an ovate subobovate 2 lobed calyx, the lobes produced and decurved. The upper lip of the corolla has a short truncate base, with a triangular tooth on each side. The flower is large and crimson, varying to white. It is found in marshes and wet meadows, particularly in the north of England and is said to be injurious to cattle. This is the Pedicularis Nervosa of the North, and is called to the Pedicularis Herba of Columella. 6, 30, and of Scribonius Largus, P. syriaca has a stem branched at the base, erect, the branches long, spreading, and prostrate; the leaves pinnate, lobules ovate and deeply toothed. The upper lip of the

There are various cases in the reports in which the question of appropriation of payment has been discussed. (Bodleian and Purchas, 2 B and Ald. 29; Simpson and Ingham, 2 B. and Cr. 65; Pemberton and Oakes, 4 Russ. 154; and others.)

PEAR-GAGE. The principle of Smewon's pear-gage, for measuring the exhaustion of a receiver, differs from that of the other gages, in that the measurement does not take place until after the air has been re-admitted into the receiver. Suppose a wire working through a collar in the top of the receiver and supporting a tube open only at the lower end. Under the pressure of the air the tube will be forced into the receiver, so that by lowering the wire the open end of the tube may be immersed in the mercury. The exhaustion being made before lowering the wire, the air in the tube will be compressed, and if the wire be now raised, the tube being scattered into the receiver, the mercury will rise in the tube until the elastic force of the compressed air is the tube, together with the column of mercury and mercury balances the pressure of the external air. A gage attached to the tube shows, by the height of the mercury, what was the original rarefaction.

Now it is plain that while the ordinary gages show the actual amount of the rarefaction of the receiver, this pear-gage shows a much higher degree of true rarefaction than the ordinary gage.

For further detail see the article 'Pneumatics' in the Encyclopaedia Metropolitana.

PECOPTERIS, a genus of fossil Ferns, of which the species occur abundantly, both in the coal-measures and the colivic strata. (Bromiart.)

PECULIARS, COURT OF, is one of the English ecclesiastical courts of the Church of England. It is the third court of the archbishop of Canterbury, the other two being the Court of Arches, or supreme court of appeal, and the Prerogative or Testamentary Court. The Court of Peculiars takes cognizance of all matters relating to the various Peculiar churches of the Diocese of London, another in the diocese of Rochester, another in the diocese of Winchester, each comprising several parishes; and some others over which the archbishop exercises ex excommunication of members of bodies independent of the jurisdiction of the several bishops within whose dioceses they are locally situated.

(Political Dictionary, article 1 Ecclesiastical Courts.)

PEDICELLATUS, from the Latin word pediculus, a louse, which perhaps may be considered to be adopted by the English law, though the decisions are by no means uniform in this respect. (Note 20. Digest 46, q. 9.) The principles laid down apply to distinct debts on different accounts (cause). If there be dealings between two persons which are all of one uniform and continuance nature, as for instance between a banker and his customer, there is no
corolla as in the last species, the flower large and rose-coloured. It is found on wet, healthy, and rather hilly grounds in Sicily, Europe, and Great Britain. The expressed juice of the herb, or a decoction, has been used with advantage as an injection in scrofulous ulcers. It is injurious to the sheep that feed on it. There are 75 other species of Pedil- 
vulum in the world, each differing from the other in the habit to any useful purpose. They are found chiefly in Europe and Northern Asia. All these herbs are very shy of cultivation. Pest soil and a moist situation suit the generality of them. All require a pure, light, loamy soil to which sand or peat is added to this end they should be grown in pots. It has been affirmed that these plants breed like the animals that feed on them; the truth, however, appears to be that they indi- cate certain diseases in the body of an animal, warning the owner of an unhealthy state of the animal, and thus cause them to gene- rate vermin. (Don Gardner’s Dictionary; Babington’s Manual of British Botany.)

PEDRO, DON, Emperor of Brazil and King of Portugal, was the son of John VI., king of Portugal, and was born at the castle of Sesimbra on the 12th Oct., 1767. When young he was the active witness of the long series of political troubles which distracted Portugal, and which are fully de- tailed in another part of this work. (Portugal, P. C.) At the age of 18, in 1785, he was sent in a letter of audience to Queen Maria Isabella, in their exile to Brazil. The misfortunes which had befallen his family proved an advantageous school for his political education; they became the means of deve- loping in him the firmness, the sagacity, and the cunning necessity of depending on other sources than those which should arise from his own talents and energy. He applied himself with considerable success to the acquisition of various languages, while he devoted the hours usually spent in recreation to the cultivation of poetry and music.

At the general peace of 1815 a marriage was contracted for the young prince of Brazil, the title by which he was then known, with Maria Leopoldina of Austria. At that period the colony of Brazil was raised to the rank of a kingdom, and, when, in 1820, John VI. was recalled to Portugal by the Cortes, Don Pedro remained as regent in that country. (Brazil, P. C.) His first position in political life was, as will be seen by reference to the article Brazil, P. C., one of peculiar difficulty; to preserve the authority with which he had been intrusted, and to secure the peace and prosperity of the kingdom, required the exercise of diplomatic skill, and a firm resolution of no ordinary kind. The Cortes of Portugal were desirous of reducing Brazil to its ancient position as a colony, and to confine its commerce to the mother country; they also designed for it a new system of government by dividing it into provincial administrations. The prince regent, sensible of the impolicy and injustice of this scheme, placed himself at the head of the movement against it, and refused obedience to the attempted innovations. The Portuguese troops stationed at Pernambuco and Rio Janeiro were sent back to Europe, and, on the other hand, the Portuguese commander in Bahia, the maintained possession of that town, and expelled it from the militia. Civil war was the necessary consequence of these proceedings, and on the 13th of May Don Pedro was proclaimed protector and perpetual de- 

feudor of Brazil; and, finally, on the repeated refusal of the Portuguese Cortes to abandon their design, the independence of Brazil was declared; and the prince, yielding to the popular wish, was proclaimed emperor on the 12th of October, 1822, and was crowned on the 1st of December in the same year. The details of the war which followed with Portugal, the constitution which was adopted by the Brazilians, and sanc- 

tions by the emperor, will be found elsewhere. (Brazil, P. C.)

Though Don Pedro appears to have satisfied the exigencies of the new state by granting it a constitution based upon liberal principles, it did not secure the government continued to manifest themselves. The long anarchy which had existed in the provinces rendered the inhabitants indisposed to submit to regular rule, and the instinctive hatred of the Brazilians towards the Portuguese diminished the popu-

larly of the ruler. Insurrections broke out at Pernambuco, San Salvador, and Bahia, which were however speedily checked. In 1825 the independence of Brazil was recogn- 

ised by the powers, and the government continued to be in a state of social and political depression. The empire split up between Brazil and the neighbouring republic of Buenos Ayres (Plata, La, P. C.) respecting the possession of a territory named the Banda Oriental, the inhabitants of which were desirous of annexing themselves to the new empire, and a war ensued, which terminated unfavourably to the interests of Brazil. To this cause of discontent another was added by the death of John VI. in March, 1826, and the consequent succession of Don Pedro to the crown of Portugal. This event excited the jealousy and animosity of the Brazilians, and to this end they should be grown in pots. It has been affirmed that these plants breed like the animals that feed on them; the truth, however, appears to be that they indi- cate certain diseases in the body of an animal, warning the owner of an unhealthy state of the animal, and thus cause them to gene- rate vermin. (Don Gardner’s Dictionary; Babington’s Manual of British Botany.)

The throne of Portugal, which Don Pedro had resigned in favour of Donna Maria, had been usurped by his brother Don Miguel, whom he had absolved and reinstated in his domin- 

om. (Portugal, P. C.) His object was now to recover the country from the usurper, and to reinstate his daughter in the rights of which she has been deprived. The plan of the enterprise was managed by the secret advice of the king himself, who was joined by the exiled Portuguese who had espoused his cause, at the head of whom was General Saldanha, and a great number of foreign adventurers. For the details of the civil war which ensued we must again refer to another part of the Cyclopedia. (Portugal, P. C.) On the 26th of May, 1832, Don Miguel was reduced to the neces- 

sity of signing a convention, which left the young queen in quiet possession of the throne of Portugal under the regency of Don Pedro.

The acts of his short administration were calculated to secure for him the good will of the more liberal party in his dominions; but many of them, though they might have been expedient, were certainly unjust. He strengthened the ex- 

ternal relations of Portugal by a close alliance with England and France, and in order to give an interest to the people in the new revolution he conferred for the use of the state the property of the numerous monastic establishments in his king- 

dom. The anathemas of the Vatican were the natural result of these sweeping measures, and they were soon followed by his own excommunication. In September, 1832, the de- 

clinating state of his health compelled him to resign the regency, and his daughter, having been declared of age, was placed in full possession of the royal authority. He did not live to see the consummation of his plans, and the palace where he had been born was the scene of his death on the 24th of September, 1834.

The life of Don Pedro is chiefly interesting as it is con- 

nected with the history of the period; the difficult circumstances in which he was placed deprived him of the opportunity of putting into effect many measures of utility which he had the talent to design, and on a more quiet theatre he might have acted the part of a greater king.

PEEL (or PEELE, as the name is found in most books printed forty years ago), Sir ROBERT, the first baronet, was born 26th April, 1750, at Peel’s Cross, near Lancaster, a small property belonging to his father, Mr. Robert Peel, whose third son he was. The family, though not wealthy, appears to have been of some respectability for several gener- 

ations. It is said to have been late in the thirteenth century, and died in 1376. His son is described as William Peel of Oswaltwich, who married Jane, daughter of Lawrence Walmesley, of Darwin, Esquire; their son, Robert, of Peel’s Cross, married in 1750, Jane daughter of Henry, son of John, of Backburn, Gentleman, and had a numerous family of sons.

It is understood that the Peels had been Unitarians for some generations, and that Sir Robert was brought up in that tenet. When he became a lawyer, he was early made to serve the court, but he early gave evidence both of remarkable business talents, and of a decided ambition and determination to raise himself
in the world. He and most of his brothers were brought up
to different branches of the cotton-trade, now fast extending
under the effect of the inventions of Arkwright, whose per-
sonal success in the acquisition of wealth and station was
also fast extending, operating as a powerful example and incentive.
The merchant principles of the trade have also engaged much
of Peel's attention, though they were never indebted to him for
any improvement, so far as we are aware. He aided his fortune by his general ingenuity and sagacity,
by his unremittent activity in the management of his comprehen-
sive boldness of enterprise, and by his admirable conduct of
business, alike in its largest scope and in its minutest details.
In 1767, Robert Peel entered into partnership with
Mr. William Yates in an extensive factory at Bury, in Lancas-
tashire; and on the 8th of July, 1783, he married Ellen,
daughter of Mr. Yates, who had then just completed her
seventeenth year. His career from this time was one of
great and uninterrupted prosperity. About the time of
his marriage he purchased a considerable estate in Lancashire;
and in the course of a few years he invested large additional
sums of money in land in the counties of Stafford and War-
wick. It has been asserted that Mr. Peel's principles were originally
favourable to the French Revolution, or at least to the
class of opinion in which he had been brought up; but that
we apprehend, must be a mistake. He appears to have first
come forward as a politician in 1780 by the publication of a
pamphlet entitled 'The National Debt productive of National
Prosperity, which may be taken as evidence that his views at
that date were the very reverse of revolutionary or dis-
affected. In 1790 he was returned to parliament as one of
the members for Tamworth, in which he served with
such a spirit that it is not improbable that from that moment he entered the House of Commons, in which he
sat for the same borough in seven successive parliaments,
or to the end of the reign of George III., he was a steady
and zealous supporter of the government. We do not see,
therefore, to what period of his life we can with any proba-
ability assign his imputed republicanism. In 1799 Messrs.
Peel and Yates distinguished themselves
by their subscription to the Loan of 1798, to which we
called the Loyalty Loan. This fact is often stated in such a
way as to make it appear that the money was a munificent
gift which they made to the public. The truth is, it was
merely a purchase of so much stock in the Public Funds,
which promised and proved to be an excellent speculation,
and was evidence of nothing except the confidence of the
subscribers in the stability of the government, and their
correct views of their own interest. The entire loan, amount-
ing to 18,000,000L, was raised in a few hours, and might
probably have been doubled in amount if it had been desired
for the purpose of satisfying a mob of applicants whose
subscriptions could not be received. 750,000L was subscribed
by Messrs. Peel and Yates was far from being the highest;
the Duke of Bridgewater, for instance, subscribed 100,000.
For the Literary Fund, a sub-committee of which included
him, bearing an interest of five per cent., with a right to have
their stock two years after the conclusion of a peace converted
into three per cent. at the rate of 150L. 6s. 8d. for 100L.
capital.
In 1798 Mr. Peel further showed his loyalty and public
spirit by the part which he took in encouraging the volunteer
system. Besides assisting in the formation of the Lancashire
Pencillers, and the Tamworth Armed Association, he raised,
chiefly from among his own workmen, six companies of
which were called the Bury Loyal Volunteers, and got himself
commissioned as their lieutenant-colonel. On the 14th of
February, 1799, he was a signatory in favour of the Union with Ireland, which was soon after
printed and extensively circulated in that country. On the
24th of November, 1800, he was created a baronet.
Sir Robert Peel, the number of persons employed by whom
is said to have amounted in 1803 to fifteen thousand,
and lived for ten years after his retirement from parliament
in 1820, dying at his seat of Drayton Park, in Staffordshire,
the 14th of April. On the 13th of April, 1787, he had married a second wife, Susannah, sister of the Rev.
Sir William Henry Clarke, Bart., Rector of the parish of Bury,
then then in his fifty-third year, and who died on the
10th of September, 1824. By his second marriage he had six sons, one daughter, and five daughters;
the eldest of the former being the present Right Hon. Sir
Robert Peel. It may be remarked that, with the exception
of two daughters who died in infancy, he saw all his children
married before his death. Besides his large landed property,
which he entailed upon his eldest son, together with, it is
supposed, near half a million in money, he left about 150,000L.
to each of his younger sons, and above 50,000L. to each of his
daughters. Sir Robert Peel bequeathed 100,000L to his younger
brother upon his several children above 240,000L, besides an income
of 9000L, per annum secured to his eldest son.

PEELE, GEORGE, is supposed to have been a native
of Devonshire, and to have been born not later than 1552 or
1553, and educated in St. John's College, Cambridge, and
Pembroke College, in Oxford: he took his degree of Bachelor
of Arts in 1577, and was made Master of Arts in 1579.
In no time long afterwards he appears to have removed to Lon-
don, and thrown himself upon the world as a literary adven-
turer. In that age the preciosity always incident to the
profession of authorship was so distressingly great, that,
if pursued on by a poor man, was barely compatible
with the preservation of personal respectability; and, though
the particulars of Peele's career are but very imperfectly
known, there is evidence enough to show that it was not only
unfortunate but disreputable. His conduct is represented as
being a continual and habitual one of that which of which
Greene, who were his intimate associates and his coadjutors in
the improvement of the early English drama. It had been
conjectured that he was professionally an actor, and his hav-
ing been a player in 'The Spanish Friar' is at least not
impossible, as it was acted by Mr. Collier. A tract, frequently reprinted, entitled 'The Merrie Conceited Jestes of George Peele,' represents him as
nothing short of a common swindler. Some of the exploits
of the author of 'The Spanish Friar' are quite as absurd as
the rest of his plays, and though Mr. Collier lamented that he
had not been able to ascertain historical facts which appear
under poverty and sickness, he addressed to Lord Burleigh;
and it is a characteristic trait of the man, that, relying peri-
haps on the Lord Treasurer's ignorance of the current litera-
cure, he took care to make no claims to any authorship
in plays which were known to be the work of others. He is
not improbable that he wished to be regarded as new, he had
actually published six years before. He was dead in 1598,
when Meres, in the second part of his 'Falladis Tama," des-
pcribed his death as having been caused by his debaucheries.
In the 'Jestes' he is spoken of as a married man; and his letter
to Lord Burleigh describes the bearer as his eldest daughter.
The earliest of Peele's compositions that is known is a copy
of verses prefixed to Watson's 'A Henrikale,' which was
published in 1581; and his earliest known drama was printed in
1584. In 1588 Mr. Dyce published an excellent edition
of 'The Spanish Friar.' George Peele, with the other Life and Writings,' 2 vols. post 8vo. A reprint of this edition
with improvements and additions, appeared in 1829; and in
1589 the same editor published a third volume, which proba-
ably contains the only complete reprint of this play. A new
impression is possible to render it. The non-dramatic poems, except a few
short miscellaneous pieces and a long piece on the War of
Troy, are speeches for pagetaps (such as 'The Device of the Paget borns before Woolstone Dixie, Lord Mayor of
London, 1665,' or celebrations of public occasions, like the
'Polybvinia,' which describes a tilting-match held in the
queen's presence in 1589, and 'The Honour of the Garter
displayed,' which commemorates the installation of the unfortu-
unate Earl of Northumberland in 1593. The dramas in Mr.
Dyce's collection are six in number:—1. 'The Arraignement
of Paris,' published anonymously in 1584, and assigned to
Peele on the 'House of Commons,' and 'Chronicle of King Edward the First,' printed in 1599 and 1599,
and inserted in vol. xi. of the last edition of 'Dodgley's
Old Plays,' as also in vol. iv. of the small collection called
'The Old English Dramatic Poets.'. 2. 'The House of
Wives,' a pleasant conedect Comedie,' printed in 1595,
and chiefly remarkable as treating, in a coarse and prossic
fashion, a story closely resembling that of Milton's 'Comus.'
He had written 'The House of Wives,' which was published
in 1615, under the title of 'The Tragedy of Abelson,' printed in 1669, and reprinted in
the second volume of Hawkins's 'Origin of the English Drama,'
1775; 5. 'The Battle of Alsace,' printed in 1594; 6. 'The
Famous Historie of Marmion's Captivity,' and 'The
Claymidey,' printed in 1599, with no author's name, but attributed
to Peele by Mr. Dyce, on the faith of a MS. marking in a
very old hand on the title-page of a copy, to which not a little
corroboration is afforded by the play itself. Thomas Campbell, in his 'Specimens,' has spoken of Pocel more favourably than any other critic. There is more of justice in the cool estimate of his merits formed by Mr. Dyce and others. 'Those of his works which are not of the English drama,' says Combe Knight, 'afford evidence that he possessed great flexibility and rhetorical power, without much invention, with very little discrimination of character, and with that tendency to extravagance in the use of his imagination which exhibits small acquaintance with the higher principles of the dramatic art.' His inferiority to Marlowe is great and unquestioned; and perhaps it is only his musical though monotonous versification which claims the distinction of an imitation of the Greek drama.

PELLERIN, JOSEPH, was born at Marli-le-Roi, near Versailles, April 27, 1684. He studied at Paris, and, besides the Latin and Greek languages, made himself master of the Italian, Spanish, and English. After completing his college studies, he learned Hebrew, Syriac, and Arabic. His knowledge of the three modern languages procured him, in 1706, a situation in the navy-office (bureau de la marine), where he was employed in making translations and extracts in those languages from the foreign correspondence of the minister.

Several letters written in cipher having been seized on board a Spanish frigate on her voyage from Barcelona to Genoa, in 1707, Pellerin in a few days deciphered them without the keys. They were found to be important communications, some in French for the court of Turin, and some in Italian for the court of Naples. Torey, then minister for foreign affairs, having recommended Pellerin, soon afterwards appointed him secretaries private (secretaire de cabinet) to the secretary of state for the navy; and he held the situation when, on the death of Louis XIV., the business of the office was in the hands of the queen. In the meantime, the greater part of the French admirals, particularly de Briguez, had been appointed by Pellerin a commissioner of the navy (commisariat de la marine) in 1718, and sent him on service to the great harbours of France, and in 1719 he was destined to make a general visit to all the harbours of the kingdom, at the expense of ministry took place, the council of the navy was suppressed, and other measures were decided on. Pellerin however still continued attached to the department of the minister for foreign affairs, and was made secretaire general, and afterwards was made first clerk of the navy (premier commis de la marine), in which office his activity, probity, and firmness, combined with the anxiety of his manner, met with universal approbation. In 1745 bodily infirmities compelled him to retire from the public service. His son, who had served in the navy and in the naval department of the government, succeeded him in his office.

Pellerin, during his long service of about forty years, had used the opportunities which his situations afforded him in the collection of a considerable number of coins and medals, at first from French sources and afterwards from abroad as material for the formation of a cabinet of antiquities. To occupy his leisure and alleviate his sufferings, after his retirement, he began to read, explain, classify, and arrange them. His early studies in the oriental languages, as well as in his mother tongue, were made use of by him as a source of much gratification to him. Such was the origin of that magnificent collection of coins and medals which he formed in the course of the subsequent forty years of his life. He died at Paris, August 30, 1782, in his ninety-ninth year.

In the arrangement and classification of his medals Pellerin adopted a system different from that of any previous collector. Instead of distributing them in drawers according to difference of metals, and arranging them alphabetically without reference to the countries to which they belonged, he placed them according to certain geographical divisions, preserving however an alphabetical arrangement of the medals of each country, each medal being placed in the division of its country. His descriptions of the medals, with his comments and remarks, formed a large Catalogue raisonné, which he published under the title of 'Recueils de Médailles de Poiret, des Mémoires de Pellerin, de la Bibliothèque de M. de Vitry, et de la Bibliothèque de M. de la Fontaine,' and which, from its publication in 1791 to 1798, its delightful in flavour of the period, and his system of arrangement and classification similar to that of Pellerin was adopted by Eckhel, in his 'Doctrina Numorum VETERUM.' [Eckhel, F. C.] Pellerin and Eckhel were both very industrious in this division; Eckhel writing in 1770 a collection, which consisted of 39,500 medals, was bought by the King of France, in 1776, for 300,000 francs. The king afterwards allowed Pellerin, as long as he lived, the use of the whole of the royal collection, which then amounted to about 44,000. The most important additions which have since been made to numismatics relate to the coins of the kings of Bactria. [Prisse, JAMES, P. C.; ANGRISTAN, P. C. S.]

PELLISSON-FONTANIER, PAUL, was born at Béziers in 1624. He was deprived of his father at an early age, and was educated by his mother in the principles of the Reformed church. He became an advocate, took his degree in law, and in the profession of the law, and to that profession he was also destined. He studied successively at Castres, Montauban, and Toulouse, and acquired an intimate knowledge of the best classical authors, of the Institutes of Puffendorf, and of the Green's nature. To the study of civil law and jurisprudence he especially devoted himself; the fruits of which shortly afterwards appeared in a paraphrase of the Institutes of Justinian, which was published at Paris in 1645. He commenced his legal career with considerable success at Castres, but it was soon interrupted by a most severe attack of small-pox, which permanently affected his sight and so disfigured him that Mad. de Scodleri, though sincerely attached to him (Mesangiene, vol. ii. p. 381, Paris, 1715), could not refrain from making him the object of her wit, by remarking that he abused the permission of being ugly.

Compelled by infirmities to abandon the practice of his profession, he retired into the country and devoted himself to general literature. In 1652 he settled at Paris, where his writings had already made him advantageously known. The French Academy had elected him an associate, and the Académie des Sciences and des Arts had rewarded him by writing its history (the work perhaps by which he is best known), decreed that he should be appointed a member of it on the first vacancy that should occur, and that he should be elected a member of the Academy of Inscrip- tions; to enhance the honour, they further decided that a similar privilege should be on no consideration be granted in future to any man of letters. The same year Pellisson pur- chased the office of secretary to the Academy, an appointment which he applied to the performance of his duties acquired for him a reputation for the management of public affairs. In 1657 he was appointed first clerk to the Intendant of finances, and in the same year, by the influence of the minister where vast sums of money passed through his hands he maintained his reputation for integrity, while his increased means enabled him to render pecuniary services to the dis- tressed men of letters in the capital. Several traits of his generosity are recorded and their value is increased by the delicate concealment which accompanied them. (Ménagier, vol. ii. p. 16.) His services were rewarded by Fouquet with the appointment, in 1660, to the office of state censor. The following year he partook of the disgrace of his patron, and, as being the principal sharer in his fortunes and the supposed confidant of his secrets, was imprisoned at the Bastille, where, unaccustomed up to that time to captivity, and constantly resisted every attempt which was made to induce him to divulge anything prejudicial to the interests of his benefactor. During this imprisonment he composed the 'Mémoires,' in behalf of which he has been reckoned the finest models of that species of writing in the French language; the author of the 'Lettres de Louis XIV.' considers them the nearest approach to the Ciceronian style that French literature possesses; they are indeed alike honourable to his talents as a writer and his feelings as a friend. They became however the plea for additional severity towards Pellisson. In order to increase the rigor of his confinement he was deprived of the use of ink and paper, the want of which compelled him to have recourse to divers ingenious expedients, such as writing on the margin of his books, or on the leaf margins of printed books which he had brought with him, or making use of the system of arrangement and classification similar to that of Pellerin was adopted by Eckhel, in his 'Doctrina Numorum VETERUM.' [Eckhel, F. C.] Pellerin and Eckhel were both very industrious in this division; Eckhel writing in 1770 a collection, which consisted of 39,500 medals, was bought by the King of France, in 1776, for 300,000 francs. The king afterwards allowed Pellerin, as long as he lived, the use of the
rable value in the diocese of Auch. However, he is favour-
yably distinguished from most prolesytes by the lenient and
tolerant disposition which he evinced towards those who dis-
agreed with him; in public, he publically disapproved and opposed by his influence
and writings the violent measures which were employed by the
king's command [N v esti, P. C.] to bring his Protestant
subjects from the French royal domain. In 1571, when the
occasion of the reception of the archbishop of Paris as
member of the Academy, he delivered a panegyric on Louis
XIV., which was translated into the Latin, English, Spanish,
French, and even into the Arabic language. In 1563, having
incurred the displeasure of Madame de Montespan,
he was deprived of his office of royal historiographer, but,
at the special request of Louis, he continued to write the Life
of the King, and for that purpose accompanied him in several
of his campaigns. Nearly every succeeding year of Pellisson's
life was marked by some instance of royal favour. His death
took place at Versailles, in February, 1693. The fact of his
not receiving the Sacrament in his last moments has been
explained by the Roman Catholic writers to be owing to the
suddenness of his death, by Protestants to his unwillingness
to sanction a conversion, which they allege to be insincere,
yet a solemn act of hypocrisy. The arguments on both sides will
be found impartially stated by Bayle (art. Pellisson).

The principal works of this writer, who enjoyed a greater
reputation in his life-time than has been accorded to him since,
his Histories de France, which was first published at Paris, in 1658; the best edition is
that by l'Abbé d'Olivet, by whom it has been continued.
Paris, 1730. The fault of this work is generally considered
to be the conventional style which Bishop Sprat, in his 'Hist.
of the Royal Society of London' (part 1., sect. 19), 2, 'Histoire de Louis XIV.', which ex-
tends from the death of Mazarin, in 1661, to the peace of
Nimegum in 1678; this histo, has the faults to be expected
in the work of a professed courtier; the best edition is that
of Paris, 3 vols. in 12mo., 1749. 3, 'Abrégé de la Vie d'Anne
d'Autriche,' 1696, in 4to; a panegyric rather than a history.
4, 'Histoire de la Conquète de la Franche Comté,' 3 vols.
of 'Les Mémoires du Père Desmolet,' this work has been
greatly praised by Voltaire. 5, 'Histoire des Guerres et
Ouvrages divers,' 3 vols. in 12mo., 1749; the letters, 275
in number, are a journal of the king's journeys and encampments
in the above-mentioned campaign. 6, 'Recueil des Pucres
Galantes,' 5 vols., 1685, being a correspondence in prose and
verse between him and the Contesse de la Suse; his verse
parbutes of the elegance of his style in prose, but it is deficient
in imagination. 7, 'Réflexions sur les Différend de la
Religion,' 4 vols. 12mo., an answer to the arguments of Jules
Rousseau; on this occasion, Bayle has many
several valuable remarks in his notes on the article 'Pellisson.'
8, 'Traité de l'Escharite,' a work he left unfinished.
The Prologue in verse of the comedy 'Les Facheux' of Molière
is from Bayle's translation of a comedy of the same name 'Le
Menippe,' vol. ii., 1689, 207, 331; vol. iii. p. 131.)

PENSTOCK, a kind of small sluice or floodgate,
employed to retain or let go at pleasure the water of a mill or
other pond. A cut of a simple form of postern sluice is
given under IRIGATION, P. C. See also Sluice,
P. C., p. 142.

PENTZ, PENCZ, or PENZ, GEORG, a celebrated
German musician and composer, was born at Nürnberg
in 1590. He was first pupil of Albrecht Dürer, and he
afterwards studied the works of Raphael at Rome, probably
after the death of Raphael, but before his school was dispersed
in 1520. Most of his works are correct in design of the early
German masters, perhaps most the correct. His prints are
numerous, but his pictures are scarce; there are some at
Nürnberg, and a few in the galleries of the Grand-duke of
Schlesien. Barthz enumerates and describes 126 engrav-
ings by Pents, of which the best are seven of the history of
Tobias. He was the pupil of Marcantonio, and assisted
him in some of his prints after Raphael. (Saudart. Deutsche Academie, &c.; Doppelmayr, Histo-
rasche Nachricht von den Niederländischen Künstlern, &c.
Bartsh, Peintre-Gравeur.)

PEPPER-CORN RENT. [Rawr, P. C.] A kind of tax is a walking through or over ground for the purpose of settling boundaries.

A perambulation of a forest is a walking over the boundaries of a forest by justices or others to fix and preserve its bounds.

A perambulation of a manor is a walking over the boundaries of the manor by wardens, and parishioners once a year, or in Ascension-
week, for the purpose of preserving the boundaries. Usage will justly the parishioners in following the boundary over the lands; but in many cases, by force of custom, have been
ambulated: and there is a writ De Perambulation Facenda, which ought to be sued with the assent of both parties when
they are in doubt about the bounds of their lordships or
manors. The writ is addressed to the sheriff, who is to
examine it and make his return to the justices at Westminster
on a certain day; or to the justices of assize, under his seal and
the seals of those who make the perambulation with him. The
king may direct the writ to other persons to make the per-
ambulation, as well as to the sheriff. This perambulation made
by assent binds the parties and their heirs. But unless both
parties who assent to the perambulation are tenants in fee-
simple, it seems that the perambulation shall not bind him
who is in reversion.

Questions of boundaries are now generally determined by
actions of trespass or ejectment.

It began at the time of the Terminalias, in the month of February, to perambulate the boundaries of a
district or community. The old original boundaries of the
territory of Rome, which extended six miles from the city,
were preserved; and the tenements of the Commune,
private properties were also perambulated at the Terminalias,
and the usual religious offerings were made. This ancient
and simple mode of preserving boundaries probably fell into
disuse as late as the more modern age, and the
records of boundaries were better kept. It is stated that
the practice fell into disuse with the establishment of Christianity.
But this is not probable. The religious ceremonies might be
changed or dropped; but the custom of perambulating being still
kept up in this country in the case of parishes, leads to the
conjecture that the practice extended from Rome to other
countries which the Romans occupied or retained in
some form among the Christianized peoples in the
provinces. (Fitz-Herbert, The New Natura Brevium, p. 296; Rudorff,
in the Zeitschrift für Geschicht. Rechtsste. x. 486.)

PERCIER, CHARLES, a charlatan of celebrity, whose
name is so intimately associated with that of his friend
and professional colleague, Pierre Louis François Fontaine, that
the reputation of the one is inseparable from that of the other,
for both were imprisoned. Bayle has made several
inductions of their joint talent. Percier, whose father was
a colonel of dragons, was born at Paris, August 22, 1764;
and had for his first instructor in art one Pouisson, who
was no doubt the father of a nephew, who was master of
the school of Peyre, and afterwards studied under the elder
Gisors, another architect of considerable repute; and having
obtained the prize for a project for a Jardin des Plantes, in
1786, he went to Rome, where he was at once quite over-
whelmed and perplexed by the multiplicity of buildings and
other objects of art that at all once solicited his study. It
was at Rome that his friendship and connexion with Fontaine
commenced, and there he also became acquainted with Flax-
man, Canova, and other artists, who afterwards rose to emi-
nence. During their residence in that city, Percier and
Fontaine made the drawings which form the subjects of their
first publication, viz. 'Palais Montmorency, et autres
Edifices modernes, desainés à Rome,' Paris, 1798, a folio with 100
plates, beautifully delineated and engraved in outline. In
the interim, and for a while after their return, they had to
contend with the banishment of their Perambulation Facenda
in 1740; after which they published angaged
agitated state of public affairs was most unpropitious to their
profession, more especially to beginners in it; they were therefore
obliged to provide for their own act of existence by
making designs for various articles of ornamental manufacture
and furniture. The careful study and superior taste displayed
by them, rescued them from the obscurity to which they
would have been consigned had they been left to the
impartial judgment of the public before the public. Various decorations, executed by them
at Malmaison for the First Consul and Madame Bonaparte,
secured for them the powerful patronage of the Emperor
Napoleon, who, on the most immediate occasions of his
reign they were employed to restore, and

embellish the two palaces of the Tuileries and the Louvre, of which latter more especially the very extensive, numerous, and complicated works fully occupied them for a series of years; a notion of the magnificence of the Bourbon. This accounts for their having, with all their high reputation, been employed on so few buildings; and flattering and favourable as it was, it was not wholly without drawback, because their patrons, the last subject with respect to their own architectural creations, and their fame in them merged in the renown of their original authors. One distinct work of theirs is the arch (1806) in the Place de Carrousel, before the court of which stood the mounted statue of the latter case and other separate portions of the interior of the Louvre. The chief other monument by them is the Chapelle Expiatoire erected after the Restoration, in memory of Louis XVI. The list of their works is large; but Perout adds nothing to their professional fame, it being no more than a handsome and regular piece of street architecture.

For the general celebrity attached to their names, Percier and his colleague are perhaps, after all, mainly indebted to their publications, and not least of all to that entitled 1 Recueil de Decorations Interieures, contenant tout ou qui a rapport a l’Aménagement, folio, Paris, 1812, a collection of designs for rooms and various articles of furniture in the ultra-classic style of embellishment that was affected in France at the beginning of the century, but which was so entirely matters of mere fashion, that Percier lived to see it pass away. Another publisher, who was to gather great profit, was the "Choix des plus belles Maisons de Plaisance de Rome et ses Environs," a series not of strictly architectural studies, but pictorial views of Roman villas and their gardens. To these may be added the publication of the table given to the public of the ceremonies and pomps at Napoleon’s coronation; the other, those which took place on his marriage with Marie Louise. Besides these, there is another work attributed to Percier, which does not appear to have got into general circulation, 2 Parallèle entre plusieurs Residences de Souverains de France, d’Allemagne, de Suède, de Russie, et d’Italie, Paris, 1833, with thirty-eight plates. Percier died at Paris in 1838. 

PERCEBE. (or Percebi), a family of Acanthopterygious osseous fishes, of which the perch is the type. The Percebeae have bodies covered with rough scales, ciliated at the margin. The edge of the opercle or preopercle is dentilated or spiny. The vomer, also jaws, and usually the palatine bones, are armed with teeth. Perca, Trachinus, and Mugilus are British genera of this family. Bergas is an inter-tropical percoid genus, containing two or three species remarkable for bright-red colours, tinged with golden hues. Holocentrum is an allied genus, including very beautiful fishes, mostly tropical species. Myripristis diversicolor, Holocentrum inermis, and Trachichthys are all in different lenticular spines. Trachichthys is also a genus of this family.

PERIDINM, a genus of infusorial fossils, which occurs in the Eocene beds. (Peridinium.)

PERICHEIROCRUS, a genus of fossil Crinoid echinodermata, found in the Silurian strata. (Austria.)

PERIODUS, a fossil fish from Steepy. (Agassiz.)

PERCY, JOHN, was born in Aberdeen on the 30th of October, 1766. He received the rudiments of his education at the rural parish school of Chapel of Garioch, studied Latin at the grammar-school of Aberdeen, and in the year 1777 was entered a student of Marischal College. He seems to have been destined for the profession of the law, and was for some time employed in the office of one of the attorneys, or, as they are by local usage termed, advocates, of Aberdeen. There are some traditions of his being an inefficient clerk, and having stolen so much time from the unscientific details of the country practitioner’s office, to be devoted to higher studies, that his master losing all patience deserted his pupil, and young Percy, intent on the prospect of becoming a prosperous country attorney. Perry was master of that ordinary Scottish education which fits his owner for many of the progressive and less-established departments of business, but leaves him in the most disadvantageous position, where he in vain attempted to procure the means of livelihood. He went afterwards to Manchester, and was rather more fortunate, obtaining employment as clerk to a manufacturer. He had had an eccentric education, and was more of an invigorating his mind, and fitting himself for those higher walks of industry in which he felt an innate capacity to occupy. He had shown intelligence and ability as a member of a debating society in Manchester, and went thence in 1771 with introductions to people of some influence in London. Among the friends who had made him general promises of assistance in procuring a situation was Mr. Urquhart the bookseller. Percy had written an essay in 1770 in the most inflammatory style of the Bourbon. This accounts for their having, with all their high reputation, been employed on so few buildings; and flattering and favourable as it was, it was not wholly without drawback, because their patrons, the last subject with respect to their own architectural creations, and their fame in them merged in the renown of their original authors. One distinct work of theirs is the arch (1806) in the Place de Carrousel, before the court of which stood the mounted statue of the latter case and other separate portions of the interior of the Louvre. P E U

Martiús says P. petandria, another species, is employed in Brazil, under the name of *Rauy de Pipí*, in warm baths and lotions for defective contractility of the muscles or in paralysis, when the feet are cold. (Lindley’s *Flora Medica*; Burnett’s *Outlines of Botany*.)

PETROSELINUM (parente sylwvov, which means ‘rock parsley,’ rock being the habit of the species,) a genus of the Umbelliferae. It has an oblong calyx; roundish entire incised petals, scarcely emarginate, contracted into an inflexed lobe. The disk is short and somewhat antrorse. The fruit is oblong and compressed. The species are smooth-branched herbs. The leaves decompose, with wedge-shaped segments. The involucres many-leaved; the flowers are white or greenish, unisexual; those of the disk often sterile. The stamens longer than the style.

*P. sativum*, common Parsley, is described under *Parsley*, P. C.

P. sativum, Corn Honewort, has pinnate lower leaves; no petiole; ovate, ovate and serrated, the upper leaves entire or trifid. The umbels are very irregular, the general inflorescence having from 1 to 2 leaves. The flowers are whitish, in dense axillary racemes, and from the fact of its being cured a swelling in the cheek called a bone.

The species are easily cultivated and can be raised only from seed.

(Don’s *Gardener’s Dictionary*; Babington’s *Man. of Brit. Bot.; Lindley’s *Flora Medica*; Burnett’s *Outlines of Botany*.)

PEUCE, a fossil Coniferous tree, of which the species occur in the colitic strata. (Witham.)

PEUCE-DANUM (the πυξίδανος of Theophrastus and Dioscorides, from ψύξις a pine, on account of the resinous smell of the plant), a genus of plants belonging to the natural order Umbelliferae and the tribe Peuceae. It has a calyx of 5 teeth, obovate petals, contracted into an inflexed segment, emarginate or nearly entire. The fruit has a dilated thin flat margin, the carpels with equidistant ridges, 3 dorsal flaments, 2 lateral close to the base of the dilated margin obsolete. The stectarices have single linear vittae. The species are perennial, generally smooth. The leaves are pinnate, more or less compound. The flowers are white, yellow, or yellowish green.

P. officinale, Sulphur-wort, or Hog’s-fennel, is a smooth herb 3 or 4 feet high, with a resinous juice and a strong sulphurous smell. The leaves are four or even five times divided, with a broad, smooth, almost obtuse segment. The involucres 3-leaved and deciduous; the pedicels much shorter than the flower. The fruit of a pale brown colour, the vitre of a deep chocolate; the primary ridges much depressed and flattened, the second them a little obtuse. With a light crimson vitre very evident upon it. It is native in marshy and shady places throughout Europe and in Great Britain. The juice of the root of this plant is resinous and has a peculiar, strong, bitterish, acrid taste, resembling the qualities have been attributed to it, and it is reputed anti-aphomodic and diuretic, but it seems to be rather a dangerous internal remedy.

P. ocecum, a taper striated stem. Trifoliate leaves with the petioles broken back, the leaflets remote, ovate, deeply pinnatifid and shining. The fruit is roundish oval. The flowers white with a tinge of blue. The leaves and stem are bitter and aromatic, and are used in a higher degree. They were formerly used as stimulants, and are still esteemed in some countries.

P. montanum is a native of the north and middle of Europe, and has tapering simple root with many long fibres. The stem is erect from 4 to 5 feet high, hollow, deeply furrowed, smooth branched, and corymbous at the top, and of a bright purple colour at the base. There are about 5 or 6 leaves on a stem, which are alternate, remote, and with bipinnate divisions; the leaflets are opposite, deeply pinnatifid, dark green and smooth; the petioles striated, smooth, with a reddish membranaceous margin. The flowers are white and numerous; the fruit is a small straw-coloured thimble. The root is said to supply the place of ginger in Russia. The whole plant abounds in a white bitter fettid juice which so hardens into a brown acid resin. It is a famous remedy in Cowland in epilepsy.

P. palustris has 3-pinnate leaves pinnatifid with linear lanceolate acuminate segments, the general involucres of many persistent lanceolate deflexed leaves. The stem is furrowed and from 3 to 6 feet high. The flowers are white, it is found in Great Britain, but rarely. Any common garden soil will suit the species of Peucedanum, and they are easily raised from seed.

(Don’s *Gardener’s Dictionary*; Babington’s *Man. of Brit. Bot.; Lindley’s *Flora Medica*; Burnett’s *Outlines of Botany*; Lindley’s *Vegetable Kingdom*.)

PEVELEY [Sussex, P. C.]

PEZIZA [H.]. (Don’s *Gardener’s Dictionary*; P. C. S. J.)

PHACOPS, a genus of Tribolites, found in the Silurian strata. (Emmerich.)

PHALEMA, one of the three Linnaean genera of Lepidopterous Coleoidea. It corresponded to the division Nocturna in the arrangement of Latreille. It included the Night-moths. The *Phalema* are now distributed among many genera, all of which form part of the division Heterocera in M. Boisdail’s arrangement of Lepidoptera.

PHALLUS. [GASTROCOMIUM, P. C. S. J.]

PHANTOMS, a genus of fossil Gasteropoda, from the mountain-limestone of England and Ireland. (Sowerby.)

PHANTASMOGORIA. [MAGIC LANTERN, P. C. S. J.]

PHARBITIS, a genus of plants belonging to the natural order Convolvulaceae. It has 5 sepals, a campanulate funnel-shaped corolla, 5 granulate stamens, a 3-celled rarely 4-celled ovary, and 2-seeded pods. The species of this genus are easily distinguished from others of the same order: they are mostly climbing American herbs, usually beset with retroglobose glands.

P. Nil has twining annual round hairy branches and stalked, 3-lobe, downy leaves, axillary peduncles from 2 to 3-flowered, the flowers large, of a beautiful light bright blue colour. The capsule is much shorter than the calyx, smooth, 3-celled, with two seeds in each cell. The seeds are sold in apothecaries’ shops of Calcutta under the name of ‘Kalana’ and are said to act as a purgative and an effective speedy curative, mixed like coffee, powdered, and administered in doses of from 30 to 40 grains.

It is native of the tropics in every part, and in the South Sea Islands.

There are about fifteen species of this genus, but the one described is the only one of use in medicine. They are however showy plants, and should be reared in a hotbed and then planted out in a warm sheltered situation. A light rich soil or a mixture of loam and decayed leaves suits it best.

(Don’s *Gardener’s Dictionary*; Lindley’s *Flora Medica*.)

PHASCOCHERUS. [SUZDA, P. C.]

PHILIPS, THOMAS, R.A., one of the most distinguished botanists. He was born at Dudley, in Worcestershire, October 16, 1770. He was placed very early with Mr. Edgington at Birmingham to learn to paint on glass; and he came to London in 1790 with a letter of introduction to Mr. West, and was placed in the green-house of the Earl of Chesterfield at St. George’s Chapel. In 1792 Phillips exhibited a view of Windsor Castle from the north-east; and in the following year he exhibited two historical pictures—the Death of Talbot, earl of Shrewsbury, at the Battle of Cassillon, and Ruth and her Mother-in-law. He exhibited likewise two pictures of similar classes in 1794—Cupid disarmed by Euphrosyne, and Elijah returning the Recovered Child to the Widow. He seems in the year 1796 to have already turned his attention to portrait painting, for from that year he appears chiefly in the Exhibition notices as a portrait painter, though he occasionally painted some historical pieces. It is as a portrait painter however that he acquired his reputation, and as such he will be known; for nearly half a century he was a favourite exhibitor, and for a great portion of the time the encouragement he met with was not limited to applause, as is often the case, but he was substantially patronised, and fully occupied, notwithstanding the rivalry of Hoppner, Owen, Jackson, Lawrence, and others of nearly equal reputation; few however of the nobility sat to him.

In 1804 he removed into No. 8, New Bond-street, Hanover-square, where he remained until his death. In 1808 he was made a member of the Royal Academy, to which he presented a picture of Venus and Adonis as his diploma piece; there is a fruit tree, and a strabismous thimble of this House. In 1824 he succeeded Fuseli in the professorship of painting, an office which he held until 1832; and he delivered in all ten lectures, which he published together in one volume 8vo. In 1832, dedicated to the Earl of Egremont, under
PHI PHI

the title 'Lectures on the History and Principles of Painting:'
the sixth on Design; the seventh on Composition; the eighth on Colouring; the ninth on Chiaro-recto; and the tenth on the Application of the Principles of Painting. The subject of this paper is the solution in art, and the constructive in substance and arrangement, especially in some of the author's expositions of his views of the principles of art.

The author made a tour in Italy with Hutton, in 1894, after his appointment to the professorship, and before the delivery of any lectures, in order to be able to discharge the duties of his office more efficiently. He died April 20, 1845. He was one of the trustees of the Royal Academy.

The son of Lord Thurlow, painted in 1802; one of Napoleon, of the same year, but which was painted chiefly from memory, Napoleon did not sit for Phillips; the Prince of Wales, in 1806; Blake the painter, in 1807; Sir Joseph Banks, as president of the Royal Society, in 1809; two of Lord Byron, in 1814, one in an Albanian dress; Hetman Count Plasoff, the Cosack general, on his charger, in 1816, the horse was painted by J. Ward, R.A.; Sir P. Chantrey, in 1818; the poet Crabbe, for Mr. Murray, in 1819; Earl Grey and Lord Brougham, in 1820; the Duke of York, for the town-hall of Liverpool, in 1823; Major Denham, the Architect, in 1824; first, to exhibit at the Royal Academy in London, in 1826; Lord Stowell, Sir E. Parry, and Sir J. Brunell, in 1827; Wilkie, in 1829; Mrs. Somerville and Sir Francis Burdett, in 1834; Mr. Justice Littledale and Lord Lyndhurst, in 1836; the Duke of Wellington, in the town-hall of Liverpool, and Lord William Bentinck, in 1838; Rev. Dr. Arnold, and the late Earl of Egremont, a portrait painted in 1839; the Duke of Sussex, in the chair of the Royal Society, and Sir Nicholas C. Tindal, late Lord Chief Justice of the Common Pleas, in 1840; Dr. Shuttleworth, late Bishop of Chichester, and George Green, Esq., for the town-hall, in Dublin, in 1844 and 1845. He painted also portraits of Lord Byron and some other poets and writers for the late Mr. Murray, of Albanmear-street, comprising those of Sir Walter Scott, Campbell, Southey, Coleridge, and Crabbe the elder. He painted very few pictures besides portraits after the establishment of his name as a portrait-painter. He exhibited a piece called Field Sports in 1832; Rebecca, in 1833: a Nymph Reposing, in 1837; and in 1839 a picture of Flora MacIvor having received the letter sent to her by her brother Fergus on the morning of his execution at Carlisle. His last picture of this class is said to be the Expulsion from Paradise, at Fetworth. He was the author of the 'Lexicon of Gastronomy,' and Tract on the 'Philosophy of the Human Mind.'

[Philosophy, P. C.]

Philosophy, Positive. The distribution of philosophy in the old and the new, is chiefly to be found in the German school. Thus Kant's 'Kritik der Reinen Vernunft,' his 'Prolegomena zu einer jeden Künftigen Metaphysik,' and his 'Kritik der Urkritik,' are regarded as forming a sort of Prima Philosophia, preparatory to a positive or formal and detailed system of metaphysics. For though the philosophies which have successively arisen in Germany since Kant's day, such as the doctrines of Fichte, the Transcendental Idee of Schelling, the Phenomenology and Logic of Hegel, or the Metaphysics of Herbart, are all genealogically descended from Kant's Critic review (the reason which was made by him to engage in, of the faculties of the soul), yet Kant himself, in his Critik, did not profess to do more than pave the way for a system or dogmatic of speculative philosophy. Hence Rinner observes:—

Billig haben alle diese Lehrgemeinde nicht selbst für acht Philosophie im positiven Sinne, sondern nur für Philosophie im negativen Sinne, d. h. für universalen Protestantismus gegen alle philosophische Anschauungen des seine eigene Grenzen miskennenden Verstandes erkannt und gehalten.

Dennoch hat dieses 'Kritik' von Kant (Anders, 'Geschichte der Philosoph. Bd. iii. § 129').

These are right who have regarded Kant's doctrine not as genuine philosophy in the positive sense, but as philosophy in the speculative, or, as the a priori, or, as the speculative pretensions of an understanding which does not know its own limits. For Kant proceeds throughout, only in the way of�试题, that the idea of a thing is on Invention, the sixth on Design; the seventh on Composition; the eighth on Colouring; the ninth on Chiaro-recto; and the tenth on the Application of the Principles of Painting. The subject of this paper is the solution in art, and the constructive in substance and arrangement, especially in some of the author's expositions of his views of the principles of art. The author made a tour in Italy with Hutton, in 1894, after his appointment to the professorship, and before the delivery of any lectures, in order to be able to discharge the duties of his office more efficiently. He died April 20, 1845. He was one of the trustees of the Royal Academy. The son of Lord Thurlow, painted in 1802; one of Napoleon, of the same year, but which was painted chiefly from memory, Napoleon did not sit for Phillips; the Prince of Wales, in 1806; Blake the painter, in 1807; Sir Joseph Banks, as president of the Royal Society, in 1809; two of Lord Byron, in 1814, one in an Albanian dress; Hetman Count Plasoff, the Cosack general, on his charger, in 1816, the horse was painted by J. Ward, R.A.; Sir P. Chantrey, in 1818; the poet Crabbe, for Mr. Murray, in 1819; Earl Grey and Lord Brougham, in 1820; the Duke of York, for the town-hall of Liverpool, in 1823; Major Denham, the Architect, in 1824; first, to exhibit at the Royal Academy in London, in 1826; Lord Stowell, Sir E. Parry, and Sir J. Brunell, in 1827; Wilkie, in 1829; Mrs. Somerville and Sir Francis Burdett, in 1834; Mr. Justice Littledale and Lord Lyndhurst, in 1836; the Duke of Wellington, in the town-hall of Liverpool, and Lord William Bentinck, in 1838; Rev. Dr. Arnold, and the late Earl of Egremont, a portrait painted in 1839; the Duke of Sussex, in the chair of the Royal Society, and Sir Nicholas C. Tindal, late Lord Chief Justice of the Common Pleas, in 1840; Dr. Shuttleworth, late Bishop of Chichester, and George Green, Esq., for the town-hall, in Dublin, in 1844 and 1845. He painted also portraits of Lord Byron and some other poets and writers for the late Mr. Murray, of Albanmear-street, comprising those of Sir Walter Scott, Campbell, Southey, Coleridge, and Crabbe the elder. He painted very few pictures besides portraits after the establishment of his name as a portrait-painter. He exhibited a piece called Field Sports in 1832; Rebecca, in 1833: a Nymph Reposing, in 1837; and in 1839 a picture of Flora MacIvor having received the letter sent to her by her brother Fergus on the morning of his execution at Carlisle. His last picture of this class is said to be the Expulsion from Paradise, at Fetworth. He was the author of the 'Lexicon of Gastronomy,' and Tract on the 'Philosophy of the Human Mind.'

PHILIA'RIA was a small territory bounded by Secunia and Cornithia on the north and Arcadia on the west. The chief town, Philias, is mentioned in Homer under the name Aramythys. The old Philians were Argoli, but the population became Dorian in consequence of the invasion of the Heraclidae (Pausania, ii, 12) and the settlement of some Dorians in the territory. This little state was the mart of 200 men to oppose the Persians at Thermopylae, n.c. 480, and in the following year it sent 1000 men to oppose them at Plataea. (Herod. vii. 202; ix. 28.) In the Peloponnesian war the Philians were on the side of the Spartans, as was natural, as they were a Dorian state. Its position and comparative feebleness exposed it to hostile invasions from the Athenians, when they were leagued with Sparta, and from Sparta when a cause of quarrel arose with that powerful state. When Philus was reduced by Aegaeusus, n.c. 379, it had above 5000 citizens. ( Xenophon, Hellen. v. 3, 11.) At the time of the formation of the Achaean league, Philus was under Lacedaemon, and it was a prince who raised its power and induced the people to join the confederation. Philus is placed by Pausania at the distance of 40 stadia from Titane, and he says that the road to Philus from Sicyon was straight. At Sicyon the old Agis and Agis Giorgios (St. George), and there are said to be traces of several temples on the height above the river Anopus. Pausania mentions two temples on the acropolis, a temple of Aesculapius on the right side of the acropolis, and a theatre near it. Ceasea, a small place, was four stadia from Philus.

(Pausania, i, 12, 6c.; Strabo, p. 389, ed. Caunaou; Crater of Greece, iii. 288.)

PHILUS. [Philiasia.]

PHILOPHORUS, a genus of fossil fishes, from the Fossils of England. PHOSPHORESCENCE IN PLANTS AND ANIMALS. Organic bodies under certain circumstances become luminous, and upon the supposition that this appearance depends on the combustion of phosphorus at a low temperature, the phenomenon has been called phosphorescence. This luminosity is very constantly developed under the same circumstances in both animals and plants. It is observed both during the decomposition of the bodies of plants and animals as well as whilst they are living. The oldest observations on this subject were made on the wood of trees whilst in a state of decay. This however takes place only under peculiar circumstances. It generally occurs when the wood of trees is buried in the ground, and does not take place when wood is allowed to decompose.

Vol. II. — 8 H
in the usual way and in free contact with the air. It is also found that the phosphorescence does not take place when the wood is allowed to decompose in a damp place. Wood exhibiting this property will retain it for a long period when kept dry. In the Rhizomorphosen, on the other hand, during the night at a spot where one of its branches had been torn off, Decaying fungi have been often observed to emit this light. Travellers in tropical climates have observed that when plants containing a milky juice are wounded, the juice frequently becomes luminous, whilst it is descending the sides of the tree. The cause of this phenomenon in decaying plants is probably owing to a slow decomposition of the tissues surrounding the union of oxygen gas, but what determines the development of light under these more than other circumstances is still unknown.

In living plants luminosity has been repeatedly observed. It is most constant amongst some forms of fungi, especially of the genus Rhizomorphose. In the coal-mines in the vicinity of Dresden the species of Rhizomorphose are so numerous as to dazzle the eye by the brilliant light they afford. [Bryaule, P. C. S.]. The light from decaying wood, as also from the living Rhizomorphose, continues although they are immersed in irrespirable gases, ligned oil, phosphoric acid gas, oxygen, etc. The phenomenon in both the living and the dead can at times be seen due to the same cause, namely a blue light—often visible, in the air, around the fire—"the Elateride, and the glow-worm—the Lampyris, are the most distinguished. [Elateride, P. C.; Lampyris, P. C.]. Some of the species of the Elateride have been found in the night light occasionally, as the centipede and the common earthworm. (Maycan, Pflanzen-Physiologie, Band li; Carpenter, Animal Physiology; Lancaster, Gardener's Chronicle, 1843.)

Another class of plants in which light has been observed is the Mosses. Several species of the genus Schistostega, which grow in caverns and other damp places, have been observed to emit light. Mr. Buckland and other botanists have observed it in this country in the S. pennata; whilst Funk, Brandenburg, Nees von Esenbeck, Horsnuchze, Struve, Unger, Bridge-Briereide and Agardh, have observed it in other parts of the globe. The light was emitted in a small alga, which Bridge-Briereide called Catoptrium, a small alga, and Agardh called Polysaccus, which they supposed was parasitic on the moss. Unger named it Polysaccus, and Brielu-Briereide the most accurately, and finds that at certain seasons the urticules of this moss assume a globular form, and being partly transparent, the light is refracted and reflected in such a way as to present a luminosity on the surface of its rays.

Another class of these phenomena is that which is exhibited by the flowers of some plants. The first observation on this subject was recorded by Linnaeus, and made by his daughter Christina Linna. She was walking in the garden one hot summer's evening, when she observed the flowers of Tropeolum majus to give forth a stream of light. This was attributed by many to an optical illusion, but the fact has since been repeatedly observed on this as well as other plants. We are not perhaps in a position to say this was not an optical illusion; but if it was, one would expect that it should be more constant. It has also been seen by several observers at the same time in the same garden by Linna itself; and while others have seen it also. A correspondent of the 'Gardener's Chronicle,' October, 1844, says: I have frequently observed the luminous appearance of garden plants, and have looked for the same effect on those of the same species that have been grown in pots. I may say more especially on the Papaver pilosum, the hairy red poppy, in my garden at Worcester. In the evening after a hot dry day, the flashes of light have afforded much amusement to myself and others. It is to this phenomenon that Coleridge alludes in the following lines:

The mold on summer's evening hour
Flashes the golden-hued flower
A fair electric flame.

Decaying animal bodies frequently emit a luminous appearance, which has generally been attributed to the presence of phosphoric lime in their skeletons, which become decomposed and yield phosphores when exposed to the action of organic compounds in a state of decomposition. It is to this cause that the luminosity of putrefying fish is attributed. Light has also been observed on the bodies of those dying of spontaneous combustion. [Combustion, Stockburn, P. C. S.]

But the emission of light is a very constant phenomenon of many of the invertebrate animals under peculiar circumstances. Thus during warm weather, when a vessel passes through the ocean, very often one will observe a light being given off faintly and there streaks and stars of a brighter light. This occurs in our own climate, but the phosphorescence is much more brilliant in tropical seas. Poppit, in his 'Reise in Chili, Peru, and Tierra del Fuego,' describes a phenomenon of a similar nature in an equatorial sea. Whilst one side of the vessel is still illuminated by the last fading rays of the evening sun and the opposite side darkened by the shade of the sails, the sea in this direction already becomes brilliant. One spot after another begins to be illuminated, indistinct stripes of light commence glistening from greater depths, till at last the whole of the space is filled with a dim light. A great number of these beings are undoubtedly true night animals which conceal themselves during daylight in the dark depths of the ocean. These lights in the sea are principally produced by various species of the family Acaleph, or jelly-fishes. The light emitted by these animals seems to be due to the secretions on the surface of their bodies, for when this secretion is removed it retains for some hours its luminous character, and will even impart it to milk or water. But this property is not confined to the Acaleph; many species of Polypiere, some of the Echinodermata, and the lower forms of Molusca, also exhibit this appearance.

Some few of the Crustacea and even fishes have been observed to possess the same property.

Amongst insects this phenomenon is not uncommon. Those which possess the greatest luminosity power belong to the Coleoptere, and the Autophane tribe, namely the families represented by the fire-fly—the Elateride, and the glow-worm—the Lampyris, are the most distinguished. [Elateride, P. C.; Lampyris, P. C.]. Some of the species of the Lampyris have been found occasionally, as the centipede and the common earthworm. (Maycan, Pflanzen-Physiologie, Band li; Carpenter, Animal Physiology; Lancaster, Gardener's Chronicle, 1843.)

In the present work, we have given the results of several inquiries upon the phenomena of light in a camera-obscura, by chemical agency, permanently impressed upon prepared metallic plates; although it is intimated that similar effects had been, though less perfectly, produced by other persons. Some years ago, Mr. C. H. Smith discovered many curious facts have been discovered respecting the chemical action of light, and the various means of rendering the results of such action both permanent and visible to the eye in a pictorial form, although yet the art of photography, or light-drawing, remains in an experimental state. We shall therefore merely notice a few general points, referring the more curious to the scientific journals of the last few years, and especially to the numerous papers published in the 'Athenæum' and the 'Art-Union,' for further information as to the processes employed, the discoveries made, and the theories proposed, by the numerous individuals, in this and other countries, whose ingenuity has been called into exercise by this new and curious art. One of these individuals, Mr. Robert Hunt, secretary to the Royal Cornwall Geological Society, published in 1844, in an octavo volume, a valuable contribution to the history of the art of photography, under the title of 'Researches on Light,' professing to contain 'an examination of all the phenomena connected with the chemical and molecular changes produced by the influence of the solar rays; embracing the fundamental principles of the known photographic processes, and new discoveries in the art.'

Though not absolutely the earliest as regards the date of its discovery, the Daguerrotype claims notice before any other branch of this new branch of physical science, having been the first to attract general attention, and being also that which appears to have made the nearest approach to
practical perfection. The peculiarities of Daguerreotype pictures being already described under Photographic Drawings, P. C., it is only necessary here to refer to some of the more important recent improvements, in consequence of which the practice of the art is steadily gaining ground, it being already on the point of extending itself to the instruction of minor craftsmen, views of buildings, &c. A pretty full account, illustrated with engravings of the apparatus employed, of the Daguerreotype process, both as originally practised in this country under the use of the original patents of Mr. Richard Beard and M. A. J. F. Claudet (both of whom had purchased licences of M. Daguerre), is given in his "Supplement" to his "History," &c., &c., and "Daguerreotype," issued in the fifty-fifth volume of the "Transactions" of the Society of Arts (pp. 89-110), is a paper presented to the Society, in December, 1843, by M. Claudet, on "The Progress and present State of the Daguerreotype Art," in which much valuable information is conveyed. In addition to such improvements as could only be satisfactorily explained in connection with a minute account of the process, these sources of information show that much has been done in rendering Daguerreotype portraits more correct and more pleasant by the improved management of light, and by placing behind the sitters painted screens, to relieve the head, and to form artificial features. In this process the original process arose from the circumstance, that, as the image produced in the camera-obscura was totally invisible until brought out by a subsequent exposure to the vapour of mercuric bromide, the action of the light could not be stopped, to avoid, on the one hand, an image imperfectly developed, and, on the other, the misty, indefinite appearance occasioned by the unavoidable motion of the subject, the animal (or object), and the discoloured or burnt appearance of an image which has been exposed too long to the chemical action of light. This inconvenience is remedied by M. Claudet's method of applying the mercurial vapour in the camera-obscura simultaneously with the action of light, and providing means to enable the operator to watch the progressive development of the image. One important class of improvements has reference to the object to be photographed. It is to be prepared by the subsequent action of light or other means, the Daguerreotype image. M. Claudet, in the paper above referred to, after alluding to some inventions for this purpose, observes, that it was left to Mr. Fizeau to discover what has proved one of the greatest improvements in the Daguerreotype process, and which consists in fixing the delicate image by means of a transparent coating of gold, applied by boiling upon the plate a solution of chlorate of gold, which not only renders the image more durable, but has the advantage of increasing the tint, so that a picture fixed by Mr. Fizeau's process is rendered more forcible, and the mirror-like effect is almost destroyed. M. Claudet, in his "Daguerrotypie," pp. 292-295, is the author of a number of experiments, by M. Ulex, of Hamburg, to test the durability of Daguerreotype impressions, from which it appears that they may be rendered insensible to the action of light by being boiled in a solution of boracic acid and of nitrate of copper, and that, even when rubbed away with leather and rotten-stone, they may be reproduced by the action of heat. On p. 292 of the same volume is an announcement of a method of Daguerreotyping in colours, by Professor Böttiger, of Frankfort-on-the-Main, by which, however, it is observed that "as yet he has only succeeded in bringing out three colours, of which the flesh-colour is the most perfect." In the absence, however, of any further and fuller account of this invention, we are led, from the results obtained by other experimentalists, to suspect that in this, as in the other cases about to be mentioned, the colouring was not simply the result of the action of various colours on the plate, but was the result of the action of Daguerreotypes, some of which make a tolerably near approach to the effect which might be expected if colours could be fixed in the camera-obscura, the tinting being produced by the application of fines and of spirit to the surface of the photographic impression, which is previously coated with an alcoholic solution of copal, and nearly dried; so that the colouring, which is so delicately performed as not to impair the distinctness of the image, is due to the volume of spirit, and not to the action of light. Since this mode of colouring photographic drawings has been in use, a new and ingenious process has been invented by C. G. Page, professor of chemistry in Columbia College, U. S., and wash the plate in a solution of nitrate of silver, the mixture, applied with a soft brush, observing that the operation must be performed by candle-light. After a pause of a
half a minute the paper should be dipped into pure water, then blotted dry, and finally dried at a considerable distance from a fire. It is then ready for use, and if kept in a press, sealed up, it will sometimes keep good for three months; but as this is not to be depended upon, Mr. Talbot recommends the final preparation of the paper only a few hours before using it. It is so sensitive, that a momentary exposure to the light of a cloudy window, is sufficient to produce an impression; but the impression so produced is latent and invisible. In this state the paper is subjected to the action of light in a camera obscura, after which the image is renewed by washing it again with the gallo-nitrate of silver, and warming it before a fire. In some cases, however, a strong impression will become visible in a minute or two after applying the gallo-nitrate of silver, without the aid of heat. The image thus brought out is subsequently fixed, rendered permanent by washing with water, lightly drying with blotting paper, and then washing with a solution of bromide of potassium containing 100 grains to eight or ten ounces of water. This solution the paper is again dipped in water, and finally dried. The picture thus produced is what is termed a negative one, in which all the light parts of the object represented are shown as a dark colour, and the representatives the reverse of the original in position. It is, however, according to Mr. Talbot’s second patent, rendered transparent by the application of wax, and by laying it face downwards upon a sheet of paper, and exposing both to the light, a copy is produced in which the objects are brought into their true position, and the right effect of light and shade is obtained; the copy, or secondary impression, having been obtained from the appearance of a sepia drawing. By this arrangement one original negative Calotype may be employed to produce a great number of secondary positive copies; and although it sometimes grows faint after frequent repetition of the process, its strength may be renewed by washing it in gallo-nitrate of silver, and subsequent warming. The positive Calotypes, it should be observed, may be taken upon paper prepared as above described for the negative or original impressions; but Mr. Talbot recommends for them being prepared by washing first with a weak solution of common salt, and then with a solution of nitrate of silver; as such paper, though requiring more time for the perfect action of the light, affords an image with tints more harmonious and pleasing to the eye than the more sensitive paper above described. In obtaining the secondary impressions the original and the sheet of photographic paper are laid upon a board and covered with a piece of glass, which is pressed down to keep them in close contact with each other. The images are subsequently fixed in the same way as the original. The sharpness and delicacy of Calotype, or Talbotype, pictures is somewhat impaired by these processes; so that the imitation of the light and shade that even the texture of the paper on which the negative picture is taken is imitated in the positive Calotype, by which circumstances a certain objectionable woolliness of texture is given to the whole; which will doubtless be greatly reduced, if not entirely done away with, some very pleasing representations of buildings and other objects have been produced by the Talbotype process, many of which are published by Mr. Talbot in a work appropriately called ‘The Pencil of Nature,’ the illustrations of which are not prints, but actual photographic or sun pictures. By this process, also, a perfect fac-simile of the recent Chinese treaty has been obtained, which copy is deposited among the State Papers.

The Daguerrototype and Talbotype processes, though they may be regarded as the types of two great branches of the photographic art, are but two out of many processes which have been devised for producing pictures or images by the agency of light. On this point we cannot do better than quote a short passage from the Athenæum for 1845, p. 203, promising that in the pages of that journal may be found pretty full details respecting all the processes referred to, and of some others also. ‘It is a startling fact,’ observe the editors of the article quoted, ‘that all substances, from the delightfully sensitive film which is the formation of the silver plate in the Daguerrototype process, to all the salts of the metals, and even to the metals themselves, or plates of glass or of paper, are capable of being impressed with light.

A shadow cannot fall upon any solid body without leaving evidence behind it, in the disturbed and disordered condition of its molecular arrangement in the parts in light and shade.’ ‘It is evident, then,’ he proceeds, ‘that all bodies are capable of photographic disturbance, and might be used for the production of pictures, if we knew of easy and simple methods of producing such disturbance. We are not without hope that these means may be discovered. It must be remembered that in all the best photographic processes, the images are invisible at first. In the Calotype process they are colourless, and in the Daguerrototype, the picture is brought out by mercurial vapour. In the Chromatotype, nitrate of silver is the active material for the same purpose; and it may be used to bring out the image in a minute, but pictures are formed only when a latent image is produced by the influence of the ferro-prussiate of potash. The Amblytype, and some other processes, the result of the researches of the same investigator, Sir J. Herschel, are of a remarkable character; and we therefore, he subsequendy observes, ‘led to inquire, Is this a new element, distinct from light, heat, and electricity, or is it a modification of one of these?’ Further researches only can settle this point.

Mr. John Herschel proposed the name of Actinium, invisible for this new branch of physico-chemical science, and it has been suggested that Actinium would be an appropriate term toundistinguish this chemical power from the light and heat which it produces. But with this subject we may refer to the circumstance mentioned by M. Claudet in his paper already referred to, that the operation of the Daguerrototype has been found to be much more subject to the same defects than that of other processes; and to the evidently different effects produced in the Talbotype process by different coloured rays, a circumstance which renders the foliage of some landscapes thus produced very difficult to be equally sensitive to all the rays. In this paper is an important correction of an erroneous notion which appears to have been commonly received, that the light of the moon would not set photographically, it being supposed that the chemical principle, or actinimum, of the rays of solar light was absorbed by the moon’s surface. In answer to this we are informed that photographic impressions have been obtained by moon-light both upon Daguerrotypes and Talbotype paper; thereby showing that the moon’s beams are of the same character as, though of less intensity than, the rays received directly from the sun. Both kinds of photography have been performed upon light emitted from lime ignited by the oxy-hydrogen flame.

Of an art so new it would be premature to attempt to enumerate the advantages of receiving light upon metal; but it is mentioned the procuring of accurate representations of the most complicated scenery, to be used in aid of an artist’s memoranda for the production of landscapes, architectural re-
PHYLODODOCÉ, a genus of plants belonging to the natural order Ericaceae. It has 5-parted calyx, an ovate corolla with a contracted 5-toothed mouth, 10 stamens enclosed, slender glabrous filaments longer than the anthers, short truncate cells opening by pores at the apex. The seeds are compressed and shining. The species are small evergreen shrubs, natives of the north of Europe, Asia, and North America.

P. coriacea has linear leaves with deutilculated margins, glabrous hairy peduncles; calyces lanceolate-acute segments; anthere three times shorter than the glabrous filaments. The stem is from 4 to 6 inches high, determinately branched, naked below, densely hairy above. The flower is large, pale alutaceous, the peduncles alutaceous, aggregate, and inferior. The plant is native of Peninsular and North of England. There are three other species of Phyllocladus, which are natives of North America. They thrive only in a west soil, in an open, rich, loose, composty layers. They are a genus of elegant, small, heath-like plants.

(Don, Gardener's Dictionary; Babington, Manual of British Botany.)

PHYLLODUS, a genus of fossil fishes from Sheppey. (Agassiz.)

PHYSALIS (from φυσάλη, a bladder, in reference to the inflated calyx), a genus of plants belonging to the natural order Solanaceae. It has a 5-parted calyx, a campanulate, rotate 5-lobed corolla, converging anthers opening longitudinally, a capitate stigma, smooth 2-celled berry, covered with the angular membranous inflated calyx. The species are annual or perennial herbs, rarely shrubs.

P. seminifera has several shrubby branched stems, round and downy. The leaves are in lateral pairs, short stalked, ovate, downy, and from 2 to 4 inches long. The flowers are axillary, subacute, minute, small, crowded, and of a greenish yellow or white.

The berry is red and smooth, and about the size of a pea. This plant is the φυσάλη φυσαλίσιος of Theophrastus, Hist. Plana. IX. 12; and the φυσάλη ευκερά of Dioscorides, 4. 72. 1. It is native of Europe and the southern parts of Europe. It is reputed to be narcotic, diuretic, and aleuriphasmic. The leaves steeped in oil are in India applied to inflammatory tumours, and they are used in a similar way in Egypt. Kunth recognised this plant in Egyptian mum-mies.

P. Alkekengi, the Winter Cherry, is an herbaceous downy plant, with a perennial creeping root; ovate deltoid leaves; spotting flowers, ovate coloured calyx, and subulate segments. It is a native of Europe on exposed hills, and of Japan. The corolla is a dirty white; the calyx reddish yellow, enclosing a red berry. The fruit of this plant was well known to the ancients, and is described by Dioscorides. In this country, however, the fruit is seldom eaten, and the plant is cultivated chiefly on account of its appearance. In Arabia and Armenia, Spain and Germany, however, the berries frequently supply the place of apples. They have a sour acid and not unpleasant flavour, but the persistent calyx with which they are invested is very bitter. Ray speaks of these berries as a preventative of gout, and others have extolled their diuretics, and recommended them in the treatment of dyspepsy.

P. pubescens, Downy Winter Cherry, is a native of North America and the East Indies. The whole plant is densely covered with down, and furnished with fine roundish brownish violet spots at the throat. The berries are yellowish when ripe; they are called gooseberries, and are used as a substitute for them in many parts, and when preserved with sugar form excellent preserves. It is the Camera of Brazil. All the species of Physalis thrive best in a light rich soil, and are easily propagated by seed, and cuttings will take root under a glass-house.

(Don, Gardener's Dictionary; Lindley, Flora Medica; Burnett, Outlines of Botany; Fraas, Synopsis Plantarum Florae Classica.)

PHYSONELUS, a genus of fossil fishes from the mountain-limestone from the north of France. (Aguin.)

PHYSOPERMUM (from φυσόπερμα, a bladder, and περμανήμα, a seed, in reference to the tegument not adhering to the seed when young), a genus of plants belonging to the natural order Umbelliferae. It has a one- or two-celled calyx, the fruit petals with an infixed point; the fruit laterally compressed; the carpels reniform, globose, didymous, with five filiform slender equal ridges, the lateral within the margin. The interstices with single to a thick vitia. The species are perennial herbs, the flowers white.

P. Cornubianae has triterete radical leaves, wedge-shaped leaflets deeply toothed, the stem-leaves ternoate, lanceolate, and entire; the stem from one to three feet high, erect, round, striated, minutely scabrous, bearing a few small ternoate leaves with linear lanceolate segments; the umbels are terminal; the carpels longer than broad; the coat loose. It is native only of Cornwall, in bushes and hedges; in great plenty in the neighbourhood of Bodmin. Cattle are so fond of this plant that they will eat it down to the ground. The root contains a yellow resinous juice. There are but few species of this genus. Any common cow will suit them, and they may be divided at the root or raised from seed.

(Don's Gardener's Dictionary; Babington's Manual of British Botany.)

PHYTELEPHAS. [Vegetable Irony, P. C.]

PHYTEUMA (a name adopted by Dioscorides), a genus of plants belonging to the natural order Campanulaceae; it has a 5-parted calyx, a rotate convex segments; free anthers, and filaments dilated at the base. P. orbiculare, Round-headed Rampion, has the heads of its flowers globose, those of the fruit oblong, the leaves crease-serrate, the lower ones cordate-ovate, stalked, the upper ones linear, lanceolate, sessile. It is native of the mountains of Europe and of England in chalky soil. The flowers are of a deep blue colour.

P. spicatum, Spiked Rampion, is distinguished by having the heads of its flowers oblong, those of the fruit elongated, cylindrical; the lower leaves cordate-ovate, the upper ones linear lanceolate, sessile; the flowers are white, cream-coloured, or blue. It is native of the temperate parts of Europe and in Sussex, in England. All the species are hardy and well fitted for garden borders or rockwork. They will grow in any common garden soil, and may be divided or raised from seed.

Campanula Riganocula is likewise known as the Rampion. (Rampion, P. C.)

(Don's Gardener's Dictionary; Babington's Manual of British Botany.)

PIAZZETTA, JOVAN/AI BATTISTA, one of the most celebrated of the later Venetian painters, was born at Venice in 1625 or 1635, and was first instructed in design by his father, Jacopo Piazzetta, a carver in wood. He was taught painting by his father, but he acquired his style, loggia from the works of Spagnolotto and Guecino. Piazzetta is one of the Naturalist school of painting, and he is one of the darkest of those who are sometimes called Teniers; they generally painted on dark grounds. He died at Venice in 1754.

Piazzetta's pictures are doubtless much darkened through time; they are distinguished by their strong contrasts of light and shade. His masterpiece is considered the Burial of John the Baptist, at Padua. He excelled in caricature. Many of his works have been engraved.

(Zanetti, Della Pittura Veneziana, &c.; Lanzi, Storia Pitteresca, &c.)

PICART, ETIENNE (called Le Roman, the Roman), a celebrated French engraver, was born at Paris in 1631, and died at Amsterdam in 1721. His prints, chiefly portraits and history, are of the most ingenious: they are firmly executed, but want harmony. He worked with the graver and the etching-needle, much in the style of Polliy. He is supposed to have been called Le Roman from his long sojourn in Rome, or he assumed the name that he might not be confounded with another engraver of the name of Picart. He was engraver to the king, and a member of the French Academy of Painting, &c.

BERNARD PICART, the son of Etienne Picart, born at Paris in 1663, was a designer and also a distinguished engraver, and superior to his father. He was the pupil of Le Clerc; his best works are those executed in France; in Amsterdam, to
which place he accompanied his father in 1710, he worked exclusively for the booksellers, and became mannered, met- 
tallic, and merely ornamental. A great many of his prints are from his own designs, in which he imitated the style of 
occasionally the firm of Cuper and Coppel. He was 
imitating the styles of other engravers, and he published many 
prints of this class which are said to have deceived col-
glectors; Picart used to call them Impostures innocentes, 
and they were so minutely imitated under this title that a 
number of them were sold with a list of his works, at Amster-
dam, in 1738, after his death. His prints altogeth
amount to about 1500; and one of the best of them is a Slaughter of the Innocents, after a design of Ruben, of it. The 
openings of the Tomb of Nitocris, after Le Sueur, is also one 
of his best prints; it is much in the style of Girard Andran. 
He died at Amsterdam in 1738. 
( Watel et Deveau, Dictionnaire des Arts, &c.; Huber, 
Manuel des Amateures, &c.)

PICO is one of the Azores, or Western Islands, so called from the 
remarkable volcano which it contains, and which is 
called "the Peak" (Pico). This island lies between 28° 9' and 
28° 42' W. long., and between 38° 15' and 38° 38' N. lat. It extends from west-north-west to east-south-east 
about forty-five miles, and is about eight wide towards 
its western extremity, and where it is widest, where it 
grows narrower as it proceeds farther east, until it terminates 
in a forked rock hardly a mile in width. The average 
width is about five miles. This gives an area of 225 square miles; 
which is nearly the same size as the Isle of Wight.
The coast-line is bordered by rugged rocks, which form no 
port nor allow an anchorage; at Lagoes, on the south coast, 
is a small cove, in which small craft find shelter. The western 
distance of the nearest rocky surface from the sea is about 
from the shores towards the peak, which occupies the centrepiece of 
this part of the island, and is more than 8000 feet above 
the sea. The soil is composed of lava, which in many places is 
entirely naked, and is covered in other parts with thin layer of 
earth, formed by the decomposition of volcanic matter. The 
country round the volcano and even the lower parts of 
its sides are richly cultivated, principally with vineyards; 
there are extensive plantations of mastic, and the soil is 
very fertile. From the cultivated grounds to within a third of the 
distance from the summit, it is thickly covered with splendid 
and evergreen cypress, the myrrhaya, white yew, immense junipers, 
myrtles, and tree-ferns, beyond which point vegetation begins 
to decline, and on approaching the top of the peak nothing is 
seen but moss and lichens. From the eastern base of the 
volcano a high ground runs eastward to Cape Calhagrossa, 
the eastern extremity of the island. It occupies the middle 
of the island, and descends with a very broken surface towards 
the northern and southern shores. Though this part of the 
island is lava-covered, it is entirely cultivated and forms a large 
portion of cultivable land, but is not so well cultivated as the 
country round the volcano. The southern declivities are 
much better cultivated than those which slope towards the 
orthern side, and are less covered with vegetation. 
The chief article of produce is wine. Until lately there 
were annually exported nearly 25,000 oaks. It is considered 
better than any kind grown in the Azores, and goes by the 
name of Fayal wine, because it is brought to foreign countries 
from Horta, the capital of the island of Fayal. Great 
quantities of fruit are also sent to Fayal. Grain and pulse are 
grown sufficient for the consumption of the population; the 
orchards of Pico are much valued, and large quantities of them 
are disposed of to the Americans and other traders who fre-
frequent Fayal. Among the forest-trees, the cedar and white 
 yew are greatly prized for furniture, nearly as much as 
many other woods abroad on the higher part of the 
ridge, where a large number of sheep are bred for the 
wool, which is worked by the natives into clothing for home 
consumption; goats are still more numerous. Cattle abound, 
and live on a high plane of cultivation. There is 
many plantations of mastic.
The climate is mild, neither the cold of the winter nor 
the heat of the summer being intense, but it is very irregular. 
No decidedly settled weather can be calculated on except 
between the limits of the solstices and the equinoxes. 
Showers of rain are frequent throughout the year, and in 
the winter so violent as to cause constant changes in the face 
of the earth, washing away enormous masses of basaltic 
from the mountains, and depositing them in pluvial deposits on 
the volcanic materials, and leaving the surface of the rocks 
and heights in many places destitute of soil. This island, like 
the other Azores, is subject to incessant gales, which render 
the approach to it dangerous to vessels. Earthquakes are 
very frequent, and four eruptions of the volcano are on record. 
Three of them occurred in the sixteenth century, and the last 
in 1718, which burst from the western side of the peak and 
hollowed out a large crater, and opened a facility of 
volcanic materials. 
The population, which is stated at 30,000, consists of the 
descendants of the Portuguese who settled in the Azores in 
the fifteenth century. They are an inofficious race, and 
are chiefly engaged in fishing and various industries 
around the volcanic rock, called the Isles of Magdelena, and between 
them and Pico is an anchorage in six to eight fathoms. Opposite to 
them is the town of Magdelena Ciapecovella, whence the produce of 
Pico (wine, brandy, fruits) is shipped to Fayal, and where the rich inhabitants of Horta have villas. 
It is not ascertained when Pico was first settled, but per-
haps many years after 1466, when Fayal was occupied by a 
colony of Flemings, who were soon afterwards followed by 
the Portuguese. It was not till the best portion of this island 
had been settled, that the inhabitants passed over to Pico, which 
is so difficult of access. It has always remained in the hands of 
the Portuguese, and the island is a bright red in colour. This species is found 
on dry banks in Great Britain. 

(Babington's Manual of British Botany.)

PIERMARINI, GIUSEPPE, an architect who occupies a 
foremost place among those of Italy during the last 
half of the eighteenth and at the beginning of the present 
century, was born at Foligno, July 18th, 1734. His father 
(Pietro) was a merchant, and intended that Giuseppe should 
apply himself also to business, where he had only to pursue 
the course opened and prepared for him, in order to prosper. 
Nor does he seem to have at all rebelled against paternal 
wishes, except in so far as he thought fit to give his at-
tention more willingly to mathematics and scientific 
pursuits. Having constructed for himself a geographical globe, 20 
Roman palms (about 144 English feet) in diameter, it a-
ttracted much attention among the mathematician Boscovich, who recommended, or rather, enjoined his 
father to send him to Rome to pursue his studies systematically 
under proper instruction.

He was nearly twenty years of age when he went to Rome, 
and, eager to make up for lost time, he applied himself with 
ardor to mathematics and architecture, which last he studied 
first under Poggi, and next under Vanvitelli [vanvitelli, 
P. c.], who conceived a particular regard for him. The 
master was sincerely desirous of bringing his pupil forward, 
and afforded him every opportunity of gaining practical in-
struction, the means for which were abundantly supplied by 
the Count and his friends. Vanvitelli, who lived in a house 
joining to Naples to erect the palace of Caserta, he took Piamerini 
with him as his principal assistant in that extensive work. 
Again, when Vanvitelli was afterwards invited to Milan, by 
the Austrian Government to superintend the works of altering 
and embellishing the palace there, or that now called the 
Palazzo Imperiali, for the Archduke Ferdinand, Piamerini accom-
panied him; and for Piamerini is proved a singularly im-
portant example of the fruitful employment of his 
engineers' and architects' work, the designing and carrying out of all the 
works accomplished by Piamerini (1769), who thus unexpectedly found 
himself established at Milan, the city destined to become the chief 
theatre of his professional labours, with the title of archi-

tect to the archduke, and inspector-general of buildings. Afterwards on the Academy of Fine Arts at the Brera, being established, he was appointed to the professorship of architecture. For thirty years Piermarini was constantly employed at Milan, which is indebted to him not only for most of the principal buildings at that city, but also for the more correct taste which he introduced both by his example and his precepts. He had executed nothing of any note besides the theatre Domiziana (Theatre, Table, P. C., vol. xiv. p. 263), that edifice alone would have secured his professional fame; but he erected, or else altered and improved, so many buildings as greatly to enhance the architectural character of the city. Among the private palaces or mansions by him are the Palazzo Magno, Brera, Lazacorni, Sanazari, Litta, Cusani, and the magnificent and extensive façade of the Palazzo Belgiojoso; also one of the fronts of the architect's palace. Among his public buildings are the Montedel Pèlè, the Monte Napoleone, the Louvre Pî, the Teatro della Canobbiana, and the Porta Orientale, his designs for which were adopted in preference to Cagnola's. [CAGNOLO, P. C. S.]

He likewise conducted many general public improvements, such as several new streets, the Piazza del Tagliamento, and almost the whole of the new quarter called the Contra di S. Redegonda; to which may be added the Public Gardens and their buildings. Nor were his labours confined to Milan, but were extended to the whole of the vast imperial villa at Monza; also of the Villa d'Adda in Cassano, and of the Villa Cusani at Desio, at which last place he improved and completed the church.

Since the Revolution, political changes and the state of public affairs induced him to withdraw altogether from Milan, and retire to his native town Foligno, where he occupied himself with his favourite studies, and formed a valuable collection of books, especially rich in works upon art. There he died, February 18th, 1808. The Academy of the Brera, at Milan, honoured his memory with a monument in the portico of its building.

(See: Vizzioli, in Biografia, &c.)

PIG. [HOG, P. C.; SUTTIE, P. C.]

PIG-NUIT. [BURNUM, P. C. S.]

Pigalle, Jean Baptiste, a celebrated French sculptor, was the son of a carpenter, and was born at Paris in 1714. He was the pupil of Robert le Lorrain and the elder Lemoyne, and studied three years in Rome. On his return to Paris he attracted great notice and obtained a permanent reputation for a statue of Mercury. The king (Louis XV.) purchased the statue, and the Royal Academy of Painting and Sculpture elected Pigalle a member. Louis XV. ordered the sculptor to make a Venus as a companion to this Mercury, which, however, was considered unequal to it, and the king presented them both to Frederick the Great of Prussia: they are still at Sans Souci. Another celebrated work by Pigalle is the statue of Louis XV. at Rieliea; but his masterpiece is the great allegorical group of the Duke of Saxony, Moritz von Sachsen, who commanded the French at Fontenoy, in the church of St. Thomas at Strassburg, commenced, by the order of Louis XV., in 1765, and finished in 1776. It is a great pyramid, which proclaims the glories of the marshal: the idea is singular—the marshal is represented in his own costume, and crowned with laurel, entering a tomb; on one side is Death, as a skeleton; on the other, Hercules mourning; an inscription of France is engraved on the pedestal to restrain the marshal and avert death; a weeping Genius is also in attendance, with an inverted torch: many auxiliary introductions are as necessary. The pedestal is beautifully modelled. It has been several times engraved.

Pigalle was much employed by Madame Pompadour, and his great success is said to be originally owing to her patronage. There is no great work by Pigalle in Paris: the tomb of the Comte d'Harcourt, in Notre Dame, is the principal. Among his smaller works, a figure of a child holding a cage from which a bird has escaped, obtained him great applause. He is considered one of the best sculptors of the eighteenth century, though his taste cannot be called classical. He died in 1765, as Chancellor of the antient Academy of Painting and Sculpture. The bronze equestrian statue of Louis XV., by Bonchard, which was destroyed by the populace in 1792, was finished and put up by Pigalle. [D'Argenville, Vies des fames Architectes et Sculpteurs; W. F. Fould, Künstler am Rhein.]

Pile-engine, in which a heavy mass of iron is raised to a considerable height in the air; the mass being thus allowed to fall by gravity on the head of a pile, the momentum acquired by the descent forces the pile into the ground.

Such an engine is employed in driving piles for the support of the sleepers or horizontal timbers on which are built the piers of bridges, the revetments of the ramparts of fortresses, or any other heavy mass of brick or stone work when the soil is not sufficiently firm to carry the structure. Piles are also thus driven in order to form coffer-dams in rivers, preparatory to the construction of piers or the faces of quays, basins, &c.

A pile-engine generally consists of two pieces of timber, from 20 to 30 feet long, which are braced together and retained in upright positions by means of props; at their lower extremities they are inserted in a horizontal frame constructed with four pieces of timber crossing one another at right angles and resting immediately on the ground, or upon the sides of a large vessel when the piles are to be driven into the bed of a river. The two nearest sides of the upright timbers are covered with sheet-iron in order that while the ram, or driving mass of iron (two of whose opposite sides are grooved or cut to fit the sides of the timbers), may move freely up and down, the shock arising from its impact on the head of the pile may not force it out of its place.

The ram is raised up by means of a rope or chain attached at one end to the barrel of the pile whose supports are bolted to the horizontal frame constituting the base of the machine; the rope or chain passes from thence over a pulley at the top of the two upright timbers; and, descending between them, it is made fast to an apparatus called a monkey, which, by means of forceps or tongs, remains in connection with the ram during the ascent of the latter. The monkey is a block of wood having two opposite sides grooved like those of the frame carrying the forceps, whose form is indicated in the figure: the two curved arms F D, G E, of which it consists, turn freely on a strong pin at A, and, in the descent, their lower extremities D, E, coming in contact with the top B of a staple which is fixed in the top of the ram, open by pressure, far enough to allow that top to enter into the space C; when the weight of the upper parts F, G, cause D, E, to close together under B. Thus, on turning the barrel of the crab, the monkey and the forceps are raised and the ram is drawn up with them.

At the top of the machine are formed two inclined planes, between the surfaces of which, at K H and L M, enter the arms F, G, of the forceps; these closing up in the contracted space near H and L, the extremities D and E open and allow the top B of the staple to escape, by which means the ram, being no longer retained, falls directly on the head of the pile. The weight of the monkey and forceps is sufficient to cause them afterwards to descend, the men ceasing to act at the winch of the crab; and the lower part of the forceps falling on the staple of the ram, the latter becomes engaged with the monkey, when it may be raised up and, subsequently, suffered to fall as before.

In order that the pile may penetrate more easily into the ground, or the bed of the river, its lower part is pointed and shod with iron; and, to prevent the top from splitting by the action of the ram, it is surrounded by an iron hoop. The weight of the ram employed, in large engines, is generally about half a ton.

An ingenious machine for driving piles was invented by M. Vaulouze, and is described by Desaguliers. The power of horses was employed to give motion to a horizontal cylinder, about which a long rope wound round the circumference was raised, and, while the weight was being raised, the cylinder was
PISTANO is the surname of several distinguished artists of Pisa in the thirteenth century, namely, Giunta, Niccola, Giovanni, and Andrea Pisano. Of these two artists, Niccola and Giovanni, some account is given in the Penny Cyclopedia of Art. It appears that they were contemporaries, but there were several Tuscan artists anterior to Cimabue, especially at Sienna and Pisa. [Tuscan School of Painting, p. 119.]

GIUNTA PISANO was one of the principal of these artists, and is the earliest known Tuscan painter; Niccola was a sculptor, and Giunta appears to have preceded him for a time, though not more than a year or two in date. As they were contemporaries, the name of Niccola accordingly takes the lead in the list of celebrated Tuscan artists. Giunta may have been born about 1180 or 1190. He is said to have learned painting about 1210, from some Greek artists, who were then engaged probably at Pisa, a tradition which is disputed by some Italian historians of art, who suppose that Pisa had at that period its native artists. The arts were very active at Pisa, owing to the construction of the cathedral there, which was commenced in 1063. The notice of Giunta in question occurs in an old history of the Basiliac of Assisi, by Peter Anglic, who says, 'Juncta Pisana roditur a Graecis institutis pruni ex Illius artec propheticis circa an. 1210.'

Giunta appears to have attained considerable reputation, for Friar Elia of Cortona, general of the Minoriotes, invited him to leave his monastery to assist him in painting works in the upper church of San Francesco. There are still some remains of the paintings of Giunta in this church, around the window behind the altar. He painted also a Crucifixion in 1210 in St. Agnello Chapel, near the presbytery. Other painters of this time were acquainted with some excellent water-colour medium, for another Crucifixion at Assisi, with other figures, painted upon a wooden cross in the church of San Francesco, by Giotto di Bondone Angeli, by Giunta, is remarkably solid in impasto and unaffected by water; it was painted probably about 1236, and has the following inscription upon it, according to the restoration suggested by Lanzoni: 'Juncta Pisana, Hic assumptus est Giusta di Giustiano to be the name, from the occurrence of this name in an old MS. mentioned by Morroco in his 'Pisna Illustrata.' Other existing works ascribed to Giunta are; a Crucifixion in San Ranieri at Pisa, a picture (a panel) of Saints in the chapel of the Campo Santo, and a Martyrdom of St. Peter in the church of San Francesco at Assisi (it is engraved by Lanzoni in the 'Ettura Pitti' of Lastrici). The Campo Santo was built or commenced by Giovanni Pisano in 1283. [Archaeologia, vol. xxiii. pt. 1.] Giunta was contemporary with Guido di Siena and Bonaventura Berlingieri of Lucca; and all belong to the same school, in style—brilliant compositions, powerful colour in the draperies, emaciated faces, drawn in coarse outlines with hatchings for the shadows, and elongated extremities, even with occasional short thick figures; but their forms are generally well composed and emaciated faces, the meagreness of form however, often had an historical and illustrative significance; as sorrow, resignation, or bodily suffering are almost exclusively the sentiments expressed in early paintings; as we also generally find to be the case in MSS. These peculiarities of style were not much improved until the time of Giotto, and not wholly corrected until Masaccio, two centuries later than Giunta. They were, says Lenti, faults of the times rather than of the men. Mr. W. Y. Otley possessed an old Italian distemper picture of the Crucifixion, which he supposed was a work by Giunta. Vasari has omitted the life of this painter. There is no notice of him later than 1236, but his name occurs in the time of the cathedral, 1281, and that of Andrea Pisano. Andrea Pisano was another early artist of Pisa, but nearly a century later than Giunta and Niccola Pisano. He was born in 1280, was distinguished as architect and sculptor, and is said to be the natural son of his father, who is his first of his age. He is said by Vasari to have imitated the design of Giotto in the Campo Santo. He was invited early to Florence, where he executed several celebrated works. He is said to have had a statue of Pope Boniface VIII. and St. Paul, from designs by Giotto, for the façade of Santa Maria del Fiore; they are now, with other works by Andrea, in the Sintizii garden at Villaccia; the pope is engraved in Cignarai, G. Storia della Scultura; Köhler, Realbiat, 1827; Les Modes à Florence, 1829, and his bust is in the Museo di San Marco in Florence. He died about 1348, and was buried in the church of Pisa.
when young, but smooth when old. The receptacles are compound, axillary, staminal. The flowers white tinged with purple. This plant possesses the peculiar property of intoxicating fish; the bark of the root is the part used. Dr. Hamilton, in a paper read before the Medicinal-Botanical Society of Jamaica, says that the fat from the seeds of this plant is used for the properties and uses of the plant. He says that a preparation of the root is infused into the water containing the fish, which soon rise to the top. They float perfectly insensible, and are easily taken and weighed; they recover on being thrown into pure sea-water, and neither their flavour nor wholesomeness is in any degree impaired. The same gentleman made a series of experiments on himself as to the effect of a larger dose of this preparation. His attack of severe toothache, he took a powerful dose of the tincture, which was succeeded by a profound sleep and entire relief from pain on awakening. As a topical application to cutaneous teeth he found it equally successful, and came to the conclusion that the tincture of the dogwood is more powerful than that of opium. The root-juice is used to poison the arrows with which birds are shot in the Antilles. It is said to be an effective remedy for mange in dogs: it is also reputed to possess tanning qualities. It is one of the best timber-trees in Jamaica; the wood is coarse, heavy, resinous, and almost imperishable, lasting equally well in or out of water; hence it makes a good building material, and is used for a variety of purposes. P. Carthagenensis is a native of Jamaica, Guadaloupe, and Carthagena, on the mountains. It closely resembles the forner species, and is scarcely distinguishable from it. The timber is said to suffer from a disease resembling galls, and consequently the level of the cut-frame-carved by it. Of both this and General Beatham's machinery very full details are given in N. C. L., and in "On Machinery and Manufacturers," in the Encyclopedia Metropolitana. Machines for planing flooring-boards are mentioned under House, P. C. S., p. 54; and under Saw-Mill, P. C., p. 478, is noticed a contrivance for partially planing the surface of boards before they are cut in a square. Immense saving of labour, accompanied with a corresponding improvement in accuracy, has been effected by the application of planing-machines, which are invaluable for iron, other metals, in lieu of the cold chisel and the file, worked by hand. In some instances this has been done on the principle of Bramham's machine, above referred to; but more generally the planing of iron is effected by a stationary cutter, the iron being brought under it by a reciprocating motion. For this purpose it is not usual to employ wide cutting-instruments, as for wood; but a narrow tool, cutting a mere line of the surface at once, is brought into contact with all parts of the surface to be levigated in succession; the motion of the machine is the same as if it were a plane; and in some machines the cutter is raised a little during the return of the carriage after a stroke; but others are so contrived that at the end of each stroke the machine is raised, then lowered and applied to the iron, so as to cut in both directions. A recent account, illustrated with plates, of the admirable metal-planing machinery of Mr. Joseph Clement, of Newington Butts, is given in the forty-ninth volume of the Transactions of the Society of Arts, part i., pp. 157-185.

PLANTA&G;G; a genus of plants, the type of the natural order Plantaginaceae. It has a 4-cleft calyx, a corolla with an ovate tube and a 4-parted limb. The capsules burst transversely; they are from 2 to 4 seeded. P. Coronopus, Buck's-horn Plantain, has linear pinnate leaves, with a slender ovate base, erect; the midrib of the lateral sepals with a ciliated membranous wing; the placenta 4-winged, with one seed in each cell. This species is found in gravelly and sandy places, both north and south of the British isles. It has been eaten as a salad, but it is too bitter and aromatic to be palatable, and these qualities have given it some reputation as an expectorant and vulnerary. Strangewhich accounts for a number of cases of poisoning from the food, and some very improbable cures attributed to its use.

P. maritima has linear grooved dehiscent leaves, convex on the back; the sepals not winged, the tube 2-seeded, the tube of the corolla persistent, the spike cylindrical, the bracts ovate acuminate. It is found on the sea-coast and on high mountains in Great Britain.
PLATANICA PLANTA. (Platanus, C. F.; Platano, C. S.)

PLANTAIN, CHRISTOPHE, was born in 1814, at Mont-Louis, in the French province of Toulouse, one of a family of wealthy parents. He went to Paris in his youth, and worked there some time in a bookbinder's shop, but afterwards went to Caen, in Normandy, where he learned the art of printing. After working in several of the printing-offices of France, and especially at Lyon, he returned to Paris, but the religious disturbances, which commenced about that time, induced him to remove to Flanders, and he is known to have been a master printer at Antwerp in 1550, and held office there until the year 1552. He then returned to Paris, and continued his business as a printer until the year 1600. He died in the year 1601.

PLA. lanceolata is distinguished by its leaves being lanceolate, attenuated at both ends, and rounded at the base, the petiole roughened, the spike ovate or oblong; cylindrical bracts, ovate-acute or oblong-acuminate; the capsule 2-seeded, the seeds lanceolate, the tubes of the capsules acuminate. The root produces long fibres; the neck is clothed with dense wool, and the leaves and seeds with silky hairs. This species was once cultivated as an agricultural plant, but was found to be unprofitable, and has long ceased to be so.

PLAYS is known by its ovate leaves, with short broad pubescent stalks; the sepals are not keeled; the capsules 2-seeded, and each cell containing many seeds. It is found in Great Britain, and has been called 'Way-bred,' from its prevalence on the moors. This plant has a peculiar tendency to grow in the neighbourhood of the abodes of men, and seems as though it followed the migrations of the human species. Thus, although not intentionally conveyed, it has become common all over the world, and is known in some of our settlements to the natives under the name of 'The Englishman's foot'; for with a strange certainty, wherever our countrymen have been, it is to be found. The seeds of this plant are almost entirely found of the seeds of these plants, which are covered with mucus. According to De Candolle the seeds of Plantago arenaria are exported in considerable quantities from Nurnberg and Montpellier to the coast of England, and are supposed to be in demand in the manufacture of muslin. The seeds of P. Isophloia are of a very cooling nature, and with boiling water form a rich mucilage, which is much used in medicine. It is mentioned by numerous writers, and in particular by the authors of the Botanical works. Soda is obtained in Egypt from the ashes of P. squarrosa.

(Babington, Manual of British Botany; Lindley, Vegetable Kingdom; Lindley, Flora Medica; Burnett, Outlines of Botany.)

PLANTAIN. (Plantaegnacel, C. F.)

PLANTIN, CHRISTOPHE, was born in 1614, at Mont-Louis, in the French province of Toulouse, one of a family of wealthy parents. He went to Paris in his youth, and worked there some time in a bookbinder's shop, but afterwards went to Caen, in Normandy, where he learned the art of printing. After working in several of the printing-offices of France, and especially at Lyon, he returned to Paris, but the religious disturbances, which commenced about that time, induced him to remove to Flanders, and he is known to have been a master printer at Antwerp in 1550, and held office there until the year 1552. He then returned to Paris, and continued his business as a printer until the year 1600. He died in the year 1601.

antice floras; or only such part of it as remained after decay and the transforming agency of weather had destroyed another and perhaps larger proportion? M. Bronnigtart (though not without some limiting expressions and corrections) generally assumes the fossil floras preserved in the strata as proportionate to the apparent thickness and area of the deposit; and arranging the 601 species of fossil plants in periods of geological succession, as well as in groups of natural affinity, arrives at results which appear in the following table. (We have altered the form of the original, and added the general terms Palaeozic, Mesozoic, &c., in conformity with the views advocated in this work.)

Hence it would appear that vascular Cryptogamia had their greatest predominance in the first (Palaeozic) period; that gymnospermous Phanerogamia acquired their greatest development in the third (Mesozoic) period, while true Monocotyledons and Dicotyledons appear most numerous in the fourth (Cainozic) period, and in it approximated to the proportions now actually observed between them in living nature.

But it is thought by Dr. Lindley (Fossil Flora, vol. iii. p. 5) that the proportions among the several classes and families of plants preserved in the strata may be very different from those which obtained between the plants when living, because only part of the whole living creation of plants could be expected to resist long immersion in water and the many destructive agencies which are at work on vegetable substances, so as to be preserved in the earth. And this view is to a certain extent confirmed by experiments made by Dr. Lindley, for the purpose of ascertaining the relative conservability of plants belonging to different natural families.

For this purpose, on the 21st of March, 1833, he immersed in a large iron tank full of water, 177 specimens of various plants, belonging to all the more remarkable natural orders, taking care, in particular, to include representatives of all those which are either constantly present in the coal-measures or as universally absent. The vessel was kept in the open air, and filled with water as it evaporated, till the 22nd April, 1835. The result of the experiment was then registered in respect of each plant: of the 177 tried, 56 only remained recognisable.

The numbers were thus proportioned in several natural groups:

- Acrocydium
- Dicotyledones
- Dicotyledones apetalae
- Dicotyledones polypetalae
- Dicotyledones monopetalae
- Monocotyledones

Among the Acrocydium the recognizably families were mostly Filices, and Lycopodiaceae, those being frequent in a fossil state. Among the Dicotyledones the recognizable families were numerous, especially in the Coriferae, and these abound in a fossil state. With these exceptions, the Dicotyledones plants tried were, in general, unable to remain for two years in water without being totally decomposed. The Monocotyledones plants were found more capable of resisting the action of water, especially Palmas and Selaginellae, plants which occur as fossils. Ferns exhibited a great power of resisting water, if gathered in a green state, but immersion in water caused their fructification to rot away. If we were completely assured by observation that the circumstances of the experiment were such as the whole of the plants placed in the sediments now hardened around them, were similar to those under which the above-narrated experiments were made, the inferences from the experiments might be relied on for modifying and perfecting a general view of the present vegetation of the globe. But this is not the case; we have no such assurance. On the contrary, in very many cases there is little room for doubt but the plants were speedily enveloped in mud, and, with a lapse of time, were preserved in a fresh state, sometimes in a decomposed state, according to the degree in which they had withstood atmospheric rather than watery agencies, these plants should perhaps be compared to the weeds which cover the surface of some rivers in flood, than to the rotten vegetation at the bottom of stagnant pools. This comparison has, we believe, not yet been made under favourable circumstances, but certainly the flood-transported plants of the Leith rivers are by no means to be considered as a sample of our upland flora, if even they do tolerably represent the vegetation of the river-banks.

Another important question affecting the general inferences to be derived from the study of fossil plants remains to be asked. Did these plants grow in or near to the situations where now they remain buried? The answer must be affirmative in some cases, doubtful in many, and negative in the remainder. It must be affirmative in respect of many cases of Stigmarias, if we admit the stems of this plant, with their articulated leaf-like processes, to be really the roots of trees analogous to Stigmarias and Lepidodendra; and to this, now a prevalent opinion, Dr. Johnstone Brown in his Synopsis Phanerogamiae must be affirmative in respect of the Cycadea plants of the Isle of Purbeck, which remain yet rooted as in their period of life, with the bed of soil in which they grew.

In the case of such as have hollow stems, fern-leaves, and scattered branchings and fragments of stems of Lepidodendra, which abound in the roof of many coal-beds, we cannot doubt that these have been subject to drifting, though it is not easy to determine from what distance or in what direction; as however ever the leaves retain almost universally their figure, expansion, and veins, and are represented by so much of a carbonaceous pellicle as may correspond to their whole mass, and have sometimes preserved their organisation; we may reasonably infer that they have been drifted from far, not to have been long immersed in water.

Many other cases of fossil plants occur, which require us to admit at least the possibility of their having been drifted from great distances. The large broken stems of coniferous wood found in the sandstone of Craigleith, and described by Mr. Witham, may be taken as an example. It suggests, concerning other cases of coniferous wood found in the lois, colites, Wealden and London clay, the idea of a great muddy river flowing through a woody region, and depositing in marshy plains, in estuaries, or in the bed of the ocean. In the eastern sea, the species of these, in the west, we frequently observe the wood to be perforated by Teredinus (London clay).

From the above observations we collect that the large accumulations of organic remains which belong to the coal-measures, represent approximately, though not completely nor exactly, the flora of the period of their deposition at and near the places where they are found; but that single plants or scattered small portions of them may have been derived from remote situations.

Can we, from the catalogues of fossil plants, determine what was the climate in which they flourished during primordial periods? Confining our attention to the British Isles, we remark three great accumulations of fossil plants, in three successive periods. The land vegetation of Palaeozic periods is well represented by the plants of our coal-measures; that of the Mesozoic periods by the plants of the coal-shales of the Yorkshire coast; and that of Cainozic ages is known to us in some particulars by the deposits of Sheppey, rich in seed-vessels.

The most numerous group of fossil plants, in the two former great periods, is certainly the tribe of Ferns, which, with the other vascular Cryptogamia, are known to be most numerous, in comparison of the other races of plants, in countries where the climate is warm and the atmosphere damp. Some of these are Trea-ferns, which remarkably characterize warm though not necessarily very hot climates. These are associated in great abundance large stems, like Cactaceae; others like gigantic Equisetum; others like giant Cryptogamia; others like coniferous hybrids of Lycopodiaceae and Coniferae, and a few Palms; all confirming, by their structural analogies, the conclusion that the climate of the Carboniferous period in the northern zones of Great Britain was wetter than now.
American coal-fields; and thus we find reason to admit a prevalent warm climate in the northern zones of the globe. With these conclusions from the examination of the carboniferous floras, the inferences from the oolitic floras agree sufficiently. Substituting carbonaceous plants only for those, for the lycopod and cactoform forms in these, we have a parallel series of results. And warmth of climate appears still to be indicated by the seed-vessels of Piperacea, &c., which occur in the London clay. In harmony with the data which are here generalized, into the inferences of a warm climate prevailing in the northern zones of the world, even into the Carboniferous periods, is a parallel series of data and inferences derived from the contemplation of the perished races of animals.

Granted, then, a certain high probability that the great masses of fossil plants—those of the coal-formation in particular—grew in an atmosphere warm and damp, in a climate analogous to the shores and islands of the tropics, we shall not wonder if these vegetable accumulations are of considerable extent. But they are of enormous extent; for coal, itself nothing else than plants accumulated, compressed, and transmuted, is of such thickness, even in some of the most valuable beds, as to have absorbed the growth of plants on an equal area for hundreds of centuries, if that growth was after the rain the coal was being formed in temperate, much less in even the most favourable tropical regions. In every natural effect time and force are reciprocally involved: if we suppose the ancient growth of plants to have been more rapid than the modern, the time above alluded to may be conceived to be reduced.

M. Bronniger does so suppose the force of vegetation to have varied and to have diminished towards our days, and he speculates on a cause for this, viz., a change of the constitution of the atmosphere by the gradual diminution of the proportion of its contained carbonic acid. That such a diminution of the carbonic acid of the air may have happened, nothing in physical science forbids: that it is not improbable, the late development of air-breathing animals (in the succession of life on the globe), seems to indicate; and, finally, that it really did happen to some extent at least, after the great period of carboniferous vegetation, may be maintained in a very simple argument. Calculate the quantity of carbonic-acid gas proportioned to the carbon in a given weight of coal: that quantity of the gas, at least, existed in the atmosphere before the fixation of the carbon in the plants which yielded that coal.

The whole quantity of coal actually buried in the earth is of course not known, but that which is known, submitted to this calculation, is enough to leave no doubt that previous to the Carboniferous period the atmosphere must have been loaded with carbonic-acid gas, unless compensating processes, of which we have now no example, were contemporaneously in action. The compensating process now in action is chiefly animal respiration; but we have little or no evidence of the existence of air-breathing terrestrial animals previous to the carboniferous era.

In Morris's Catalogue of British Fossils (published in 1849), occur the names of 254 species of fossil plants, distributed in 107 genera or families. We propose to enumerate these genera and show their geographical distribution so far as relates to the British Islands, according to the classification developed in the Cyclopaedia (PALAEOZOIC STRATA, P. C.; SALIENTIUS SYSTEM, P. C.) and exemplified in the article on Fossils, Fossils, P. C. S.

General Distribution of Fossil Plants.

</tbody>
</table>

In both estimates the Palæozoic Plants are more than equal a number to some of all the other strata. They are chiefly obtained from the coal-measures. Selecting particular groups for consideration, we find some characteristic circumstances of distribution (as in Tab. II.).

PLASTERING is the art of applying plastic adhesive compositions or cements to walls, ceilings, and such other parts of a building as may require a smooth and even surface, to conceal the roughness of brickwork or masonry, or the timber framing of partitions, floors, roofs, and staircases, in such a manner as to admit of colouring, painting, and other modes of decoration. The business of the plasterer also embraces the formation and fixing of ornamental cornices, centrepieces, and other ceiling and similar ornaments. 'No art in the economy of building,' observes Mr. Hosking, in his treatise on 'Building,' in the seventh edition of the 'Encyclopedia Britannica,' 'contributes more to preserve sitting rooms in a state of real neatness and elegance, and no one is less absolutely important, as far as the use and stability of a structure are concerned, than that of the plasterer,' and he further remarks that 'a hole in an application of the most perfect plaster, a damp patch in the wainscoted walls, and boarded or boarded and canvassed ceilings, or naked joints alone, are frequently found in houses of less than a century old, in both this country and on the Continent.'

In the application of stucco or stucco [Stucco, P. C. C., p. 169] to a brick wall, the first thing to be observed is to secure a rough and porous surface to which the composition may adhere readily. In this, the following points should be without the intention of receiving stucco or plaster, the joints are, as mentioned under Building, P. C. S. p. 248, left rough and prominent, instead of being drawn with the trowel, as is done for exposed brickwork; but if they be old, and have had the joints drawn, the mortar must be removed to a small depth, as for repointing, and the surface of the brickwork must be stabbed or picked over to make it rough, and to expose portions of new and porous surface. In applying the plaster, the surface must first be brushed free from dust, then wetted with water, and covered with a first coat of fluid stucco, applied with a coarse bristle-brush, after which, before it is quite dry, the first coat of coarse mortar-like composition is applied. In plastering upon quarter-paritions [Carpentry, P. C. S., p. 299], or upon the surface of timber floors or walls, in forming ceilings, a very different process is adopted. In both of these cases, the trowel is formed to receive the first coat of plaster by nailing to the timber quarterings, or to the joints in the case of a floor, narrow strips of timber, termed stilts, of the same thickness as generally are of fir, though oak is occasionally used, are about an inch wide, from three to five feet long, and either one quarter, three-eighths, or half an inch thick; these several thicknesses being designated respectively single, lath and a half, or double. They are, to ensure greater strength and elasticity, formed by splitting, or rendering, so that they are not perfectly straight, and their surfaces are comparatively rough. They are laid transversely across the joints or other timbers to which they are applied, and nailed to them, frequently with cast-iron nails, in such a manner as to leave a narrow slit or opening between every two adjacent laths. As the work proceeds, a second coat of plaster is necessary to level the under surface of the joints or floor-timbers, by attaching slips of wood, technically called furrings or firrings, before nailing on the laths, in order that a perfect level may be obtained. This is followed, and these laths, which are sometimes required in timber or quarter partitions. In lathing it is important, especially in ceilings, to select laths of uniform thickness, and also to break or vary the joints produced as above to prevent the holes from being a little too near to meet upon a joint or quartering, as much as possible. This done, the first coat of plaster, consisting of what is called coarse stuff, which is a mortar of lime and sand mixed with or without water, with the lime mixed with the sand, and another stuff, a kind of trowel, in such a way as to force the mortar through the narrow openings between the laths, behind which, in consequence of its soft and wet state, it swells in such a way as to bind the laths together, so that it could only be broken away in little bits, and by the application of considerable violence. As the security of the plaster depends upon this keying between and over or behind the laths, the plastering is applied with a great deal of care. In fact, it is evident that the hold must be in some degree interrupted wherever the laths lie in close contact with the joints, quarterings, or battens to which they are nailed, and hence to the importance attached to the proper selection of the timber. Besides the timbers narrow, or, where that cannot be conveniently done, of producing a similar effect by interposing narrow fillets between them and the laths. Projections and pannelled compartments in a plastered surface are provided for by becketting or cradling down the laths to as nearly as may be the required form.

The first coat of plaster being thus laid, the subsequent operations vary considerably according to the nature of the work, and the number of coats it is intended to apply. If it be intended to use only two coats, which, when upon laths, is technically called kind and sett, the first coat, or the laying, is levelled with the trowel, and when sufficiently dry, its surface is scratched up or roughly with a birch-broom, and a thin coat, or set, of finer plaster is laid on and smoothed with the trowel, assisted by a wet breeze and moistureIs much upon the surface of the water, being very useful for the purpose of the operation. When the first coat is laid very roughly, and the faces moist, scrabed by a species of sand blast at the same time, the second coat, the first will occasionally need sprinkling with water to facilitate their perfect union. In better work, where three coats are used, the first coat is laid very roughly, and, while moist, scraped by a species of sand blast as above; the second coat, apart, as deeply and roughly as can be done without laying the laths bare in any place, to make the second coat adhere the better. This first coat may project a quarter or three-eighths of an inch from the laths and it is, in this case, called the pricking-up. When it is so dry as to be thoroughly firm, ledges or margins of plaster, called screeds, are formed at the angles, and at intervals of a few feet across the surface, these being very useful for the purpose of the operation. The projection or level which the finished surface should have, in order that they may form gauges for the rest of the work. When these screeds, which are about six or eight inches wide, are set, the interweaving strakes or laths are filled up flush with them, the plaster being very carefully adjusted to the required surface, by means of flat wooden instruments called floats, made with one or two handles (the latter being called Derby floats), and strans, or edges, or long pieces of wood, carefully placed to a perfectly straight edge, which are moved backwards and forwards over the work in various directions, to test its accuracy. When this second coat is nearly dry, it is sweated over, and a second very thin coat of fine stuff, or second plaster made with very fine white lime, is applied as above described, the hand-float being sometimes employed to perfectly flatten and condense it, and, by the aid of occasional sprinkling of water, it is formed into a very hard surface. In performing the like operations upon a brick or stone wall there are some trifling variations, and the first rough coat is called rendering instead of laying. For minute details in this art, we refer the reader to the articles on the subject in Nicholson's 'Architectural Dictionary,' and to that department of the article 'Building' in the 'Encyclopaedia Britannica' which treats on the duties of the plasterer. Ceilings or fine surfaces that have to be whitened or coloured are finished with putty, which is a fine plaster made of the finest powdered lime. Maccerer, so commonly as to be held in solution by the water, and forming a delicate paste, which is allowed to evaporate until of the proper consistency for working; but surfaces which are to be papered are finished with a somewhat less of water, but still enough, and these are put down while the trowel, without the use of the float upon the last coat.

The various modes of finishing stuccoed or cemented surfaces on the exterior of buildings may be passed over with the remark that they are of the same nature as that which is used in protecting and decayed animal and vegetable matter, in the sand which is mixed with the lime and cement, to which causes of failure may be added the occasional presence of Sagittarian matter in the limestone, and that of the 'three things,' which, Mr. Hosking observes, 'remain quiescent for a long time, if the work were well protected from
PLA

PLO

access of moisture, which is the grand exciting cause. 'The paint, or distemper wash on the surface,' he adds, 'is generally sufficient to prevent the rain which may beat against a vertical face from penetrating, especially if the work have been properly built and well mortared, and make it shine and compact; but the evil arises from exposure above, and from the numberless horizontal unfastened surfaces which are constantly presented,' which receive and detain the water until the material is wetted, when either the water is set solid in the surface, or, warmth calls the vegetative power of its impurities into action, so that it becomes covered with minute vegetation. Hence he insists on the importance of excluding road-drift, (unless driven off, and they load the shingles from the latter matter), and all mud and clay, from the composition of both plastering mortars and mortars for building, although such materials are often used in mixing what the plasterer terms coarse stuff, under the impression that, so long as it is unctuous and tenacious, its composition is unimportant. He also recommends that care be taken to guard against the effects of wet, not only by providing sufficient shelter, and by frequent painting or distempering, but also by carefully hand-floating and trawelling the upper horizontal surfaces of all projections. Rough-cast is a cheap mode of stuccoing adopted in inferior buildings, when there are good projecting eaves to keep the walls dry, consisting of two coats of coarse lime and hair, covered, as soon as a piece of two or three yards is completed, with a semi-fluid mixture of fine clear gravel and strong lime, andc, and to give it a clustered appearance.

Mouldings and cornices are formed upon a core or foundation, either of brackets and laths, or in some cases in external work, of projecting bricks and tiles. Very trifling projections, such as cornices may be produced by a fragment projecting nails. If large, a layer of comparatively coarse stuff is applied to the foundation, and to this, when dry, is applied the finer composition of which the moulding is to be formed, as nearly as possible in the required shape. The precise form is then given by running or sliding along the cornice, with the aid of guides attached to the wall or ceiling, or both, a mould formed of a thin board, one edge of which is cut up so as to be a perfect counterpart of the profile of the moulding. The quirk or small angles, and in some cases the whole of the acting edge of these moulds, are formed of metal. The composition used for in-door cornices and mouldings is called gauge-stuff, and consists of three-fourths of the putty set in ceiling settings, to one-fourth of calcined gypsum, or plaster of Paris. As the addition of the gypsum cause it to set very quickly, only a small quantity of gauge-stuff must be mixed at once, and the moulding must be frequently sprinkled to keep its surface soft until the shape of the mould is perfectly transferred to it. The mixture of plaster of Paris with sucro for external mouldings should not be too dry, although it enables the workman to produce a sharper and better looking moulding. Such ornaments as cannot be formed by running are cast separately in plaster of Paris, being afterwards placed in the ordinary manner in their places in the ceiling or cornice, either with plaster or some other cement, or when too heavy for such a mode of fixing, by screwing them to wooden cradles fixed to receive them. Mouldings and cornices are usually formed before the final or setting coat is given to the walls and ceilings. Ornaments of paper-mache and some other substances, both lighter and less liable to injury than plaster or any plaster-like composition, have been extensively introduced of late years in internal decoration, and especially for ceilings.

Plasterer's work is measured in feet and inches, and charged by the superficial yard of nine square feet, under separate headings according to the cost of the various materials, and according to certain established rules, for areas or external angles, quirk, mouldings, and other enrichments, and curved work. It is not, however, in a great measure, incombustible, it is to be regretted that its use is not generally so modified as to render it a more important protection to buildings against fire than it commonly is. Under Fine-PROOF BUILDINGS, P. C. S., p. 42, is a table of the general charges made for the attestation of this desirable object.

PLATFORM, for guns, mortars, &c., is a floor of timber or a pavement of stone of a rectangular form which is laid on the planks of a parapet. It is to prevent the wheels of the carriage from sinking. A gun platform has one of its extremities at the foot of the interior slove of the parapet; it is generally 14 or 16 feet long and 10½ or 11 feet broad, and is laid either in a horizontal position, or with a slope of about 6 inches, from the rear down towards the parapet, in order to diminish the recoil of the gun. It consists of five joists or sleepers, each 6 inches square and laid 9 inches apart, and with planks each one foot broad and two inches thick; the planks are sometimes fastened to the sleepers by nails or screws; but in siege batteries, they are kept in their places by a string, which is fastened to the parapet, and ends on each side of the platform, and confined to them by short ropes called rack-lashings, each of which passed under a sleeper and over a riband. By this contrivance the platform may be raised and lowered, and this to a great degree of danger, the noise; and the timbers not being injured by nails or screws, may be removed and re-laid elsewhere as often as it may be necessary to change the position of the battery. Four men accustomed to the service can take up a platform in three minutes, and lay one in an hour.

A mortar platform is 7½ feet long and 6½ feet wide; the planks are three inches thick and rest on sleepers. This platform is placed at such a distance as to face the foot of the parapet towards the rear of the battery, that when discharged at the required elevation, may pass above the crest.

Along the head of every gun-platform is laid a piece of timber called hearth or barker, which, in general, serves to prevent the wheels of the gun-carriage from damaging the interior of the parapet. When the line of aim is oblique to the capital of the parapet, or towards the barker, the carriage, in contact with the wheels of the carriages, in their front, serves to keep the gun in its position.

When a gun is directed against a particular object, as in breaching a wall, the enemy is usually protected by a series of planks each six feet long, ten inches broad, and three inches thick; two of these serve as sleepers, and the other two, being placed across them, serve to support the wheels of the carriage; all the planks are kept in their places by pickets driven in the ground.

PLECTRANTHUS (from βλεκτρον, a cock's spur, and φυτος, a flower, in reference to the corolla being spurred or gibbous above the base), a genus of plants belonging to the natural order Labiata. It has a campanulate 5-toothed calyx in the floriferous state; the teeth equal or the upper one largest. The corolla with an exserted tube; the upper lip from 3- to 4-cleft, the lower one entire, usually longer and concave. There are 4 stamens, dehiscent, didynamous, the lower ones longest; free toothless filaments, ovate uniform anthers. The species are herbs, subshrubs, and shrubs. There are 5 species, the best known being Plectranthus gargano, an easy culture and propagation. Any light rich soil will suit them. The shrubby and perennial species are increased by cuttings. The seeds of the annuals should be raised on a hot-bed, allowed to dry, and are sown in spring in their places in the ceiling or cornice, either with plaster or some other cement, or when too heavy for such a mode of fixing, by screwing them to wooden cradles fixed to receive them. Mouldings and cornices are usually formed before the final or setting coat is given to the walls and ceilings. Ornaments of paper-mache and some other substances, both lighter and less liable to injury than plaster or any plaster-like composition, have been extensively introduced of late years in internal decoration, and especially for ceilings.

Plasterer's work is measured in feet and inches, and charged by the superficial yard of nine square feet, under separate headings according to the cost of the various materials, and according to certain established rules, for areas or external angles, quirk, mouldings, and other enrichments, and curved work.

A gun platform has one of its extremities at the foot of the interior slove of the parapet; it is generally 14 or 16 feet

PLÉNARTY. [UARDE IMPEDTY, P. C.]

PLINUS. [SCHEER P. C.]

PLOOS VAN AMSTEL, CORNELIS, a celebrated Dutch engraver, was born at Amsterdam, in 1726. He is chiefly distinguished for his imitations of the drawings of old masters, of which he possessed one of the best collections known, amounting to 5000 drawings by celebrated Roman, German, French and Dutch masters, from Giotto to his own time. Born of a good and wealthy family, he had every opportunity suitable for improving his taste and advancing his pursuits: he is said to have had a great number of artists in attendance on him for a fourth year; and being acquainted with all the principal collectors of Amsterdam, he commenced making his own valuable collection at a very early age. He had likewise a very valuable collection of engravings, etchings, and old prints. The portraits of Lucas van Leyden, Albert Durers, Golius, Cornelis and Jan Visser, N. Berchem, and especially Rembrandt.

Ploos van Amstel's own works consist chiefly of imitations.
of drawings of old masters, in chalk, washed, and coloured; the coloured imitations were accomplished by printing with several plates. In 1765 he published a collection of forty-six such imitations in various styles, after drawings by Zafleven, A. van de Velde, A. van der Hoeck, A. van Campen, Vandyck, Van Goyen, Gerard Dow, Backhuysen, van der Heyden, A. Bloemart, Golzius, C. Visser, van der Venne, M. Saeuwends, van der Andere, van Mander, Flinck, Bruwer, Miera, Terburg, J. Steen, De Vos, etc.

There are altogether upwards of one hundred imitations of drawings by Ploos van Amstel, and many of these are published in various stages of progress, but very few impressions were ever printed of any of them. Among these are the "Wölken," by J. Weigel in the 'Kunst Katalog,' and in Nagler's 'Künstler Lexicon.' A collection of one hundred of Van Amstel's and some additional similar imitations, with a portrait of Van Amstel, was published by C. Joci, in London, in 1821, royal folio; but only one hundred copies were printed, and at the enormous price of forty guineas per copy.

Ploos van Amstel died at Amsterdam, December 20, 1738, and on March 26, 1800, his valuable collection, with the exception of the etchings of Rembrandt, was sold by auction, and realized the large sum of 109,406 florins.

When Van Amstel's coloured prints first appeared, his countrymen, who believed in "Van Amstel," during the 'tweleve days," using various plates, and he accordingly drew off some impressions in the presence of a deputation of the Dutch Academy of Sciences at Haarlem in 1738, which decided the question in favour of the "tweleve days." (Van Eyden en Vander Willigen, Geschichte der Vaterländische Schilderkunst seit der heft der XVIII. Jahrh. 1816-1842.)

The species of this genus belong to the tribe Festucineae. This tribe is characterized by very short styles, protruded stigmas, and the glumes smaller than the lowest flower. The genus Poa has its glumes rather unequal; the upper glumes with a few crowded hairs below, scariosus at the tip, compressed, keeled, warm; the styles terminal. The species of this genus are very numerous, constituting the commonest weeds that follow the migrations of man; this genus has been used in the same nutritive manner to render them fodder for various animals. Thirteen species of this genus are described by Babington as natives of the British Islands. Of these the most common are the P. annua and P. pratensis. The former is perhaps the commonest of British plants, springing up on every neglected spot around the habitations of man. The latter is known by the name of the smooth-stalked meadow-grass, and is found in most pasture lands. P. nemoralis, the wood meadow-grass, is also a common grass in shady places. Many of the recent genera of Grasses were formerly referred to the genus Poa.

POILLY, FRANÇOIS, a distinguished French engraver, was born in Paris, by the Chateau de Vincennes, and studied under Cloquet and Daret, and studied some time in Rome. He adopted the somewhat hard style of engraving of Bloemaert in direct crosses, in which he was so successful: his drawing was less bold than his execution, and his engraved work is fine and well finished. Though Poilly's style is very laborious, there are about 400 prints which bear his name, in which however he was of course assisted by his pupils. His masterpiece is the print from Mignard's celebrated picture, now lost, of San Carlo Borromæo administering the Sacrament to the Milanese attacked by the Plague. A catalogue of his prints was published by R. Hequet in 1762; it comprises several after Raphael, including the "Vierge au Béarnais, Le Vierge au Linge, the large Holy Family in the Louvre, and other Holy Families by Raphael. Poilly died at Paris in 1693. He was the brother of Jean Baptiste Poilly who were likewise distinguished engravers.

(Waitelet et Lavoisier, Dictionnaire des Arts, &c.; Huber, Manuel des Artistes, &c.)

Poetry in the reign of Scotland, is a process for enforcing payment of a debt, against the property of the debtor. It is divided into 'personal poinding,' and 'poinding of the ground.' The former is the method by which any creditor may seize the horse of his debtor; the latter is peculiar to the holders of real rights over estates belonging to others—as to superiors entitled to feu duties or the holders of real securities entitled to payment of the interest due thereon. This court has power to decree an abstract of the estate, and pay themselves. Personal poinding is the most usual form—it is of very frequent occurrence, and is a rapid and effective process. The procedure was simplified and regulated, and was brought within the authority of the sheriff's local court, by 1 & 2 Vict. c. 114.

POISONING, SECRET. When the knowledge of the nature of mineral, vegetable, and animal compounds was less known than at present, it was not uncommon for individuals to become acquainted with the poisonous properties of various objects, and to keep this a secret for the purpose of exercising a control over the lives of their fellow creatures. The entire ignorance that existed of the means of ascertaining the presence of poisons, or of the symptoms of poisoning, made it impossible for other diseases, gave to persons who had accidentally discovered a poison a great power, and offered a temptation to persons who were supposed to have been secretly poisoned.

Beck in his 'Medical Jurisprudence,' says that 'Theophrastus speaks of a poison prepared from acorns which could be moderated in such a manner as to have effect in two or three years, or at the end of a year or two years; and he also relates that Thrasylas had discovered a method of preparing from other plants a poison which, given in small doses, occasioned an easy but certain death without any pain, and which might be kept back for a long time without causing weakness or corruption. This last poison was much used at Rome about two hundred years before the Christian Era. The laws of the Republic were so strict as to prevent the knowledge of such poisons from becoming general. The punishment for divulging secret knowledge of poisons was severe. A woman named Locusta seems to have been frequently employed for the purpose of administering poisons whose powers were known to herself alone. Locusta was employed by the second Agricola, governor of Britain, to rid their island of the heathen; and also by Nero to poison Britannicus, the son of Claudius and Messalina. (Tacitus, Annal. xii. 66; xiii. 15.)

The poisons used by the Greeks and Romans seem to have chiefly belonged to the vegetable kingdom, such as chamomile obtained, it is supposed, from the sconeite, hemlock, and poppy. One of their animal poisons is said to have been the acrid juice secreted by a species of Tectobrachite molluscs, called the sea-hare. The Apotheon of Hestor of Athens, and the Antiquities of Athens, are charged with the innovation of poison with the agent of the great medical savant. Thus the art of poison appears to have been resorted to for the purpose of committing suicide by means of an unpalatable mixture. They did not seem to be acquainted with mineral poisons.

In modern times secret poisoning has often been carried on to a great extent; although the relation of many of the incriminated persons has been generally by extenuation, and the use of mineral poisons, in the hands of persons in power over many people. At length society was discovered, arrested, and every person put to the torture, and the old president, by name Spara, with four others were publicly hanged. Several of the accused appeared the day after their arrest in one of the finery, not having time to dispose of their finery.

The practice of secret poisoning was carried to a great extent in France about the year 1670. One of the most distinguished agents in this business was Margaret d'Aubray, wife of the Marquis de Briveilleris. She formed an improperly intimate with a villain named Sainte Croix, who taught her the art of poisoning, which she put in practice in order to murder her circumstances. For the period of thirty years she had strength and action of her poisons, she assumed the dress of a nun, and distributed food to the poor, nursed the sick in the Hotel Dieu, and administered to them her poisons. She was condemned by the懂得 this 1676, and left behind her a complete catalogue of all her crimes. The principal poison used by herself and accomplices was poison. The practice of poisoning extended so widely in France that the government thought it necessary in 1675 to institute a court under the title of Chambre de Poison, or Chambre Ardente. The powers of this court were abused, and very shortly after its institution it was suppressed.

Wherever evidence has been left sufficiently point to admit of an inquiry into the nature of these secret poisons, it
has been found that they contain ingredients well-known at the present day. It is only where the sciences of chemistry and medicine are not sufficiently known, or where they are neglected, that we find cases of secret poisoning.

In this country we have recently seen an instance at Hapspurgh in Norfolk, where, from the neglect of inquiry, a man succeeded in poisoning at different times his wife, two grand-children, a son, and several of his friends, during the night, in all about two or three hours, amounting in all to 16 or 18 people, and eventually poison himself without discovery till after his death. Secret poisoning is not more frequent in countries in which the country is well populated than in what is called the nation, but it is not an uncommon phenomenon in uncivilized nations. Dr. James, in his account of the Besouct Expedition, says that the chief, Black Bird, of the Omahas, gained great reputation as a medicine man; his adversaries fell rapidly before his potent spells. His medicine was arsenic, furnished for this purpose by the voyagers of the traders.

(Beckmann, History of Inventions; Beck, Medical Jurisprudence; Adams, Edinburgh Medical and Surgical Journal, vol. 1, 1828.)

POISSON, SIMONE DENIS. We regret that we are unable, from want of materials, to give any account of the private life of this very eminent mathematician. He was born June 21st, 1781, in a humble station, and was admitted to the Ecole Polytechnique in the first year of its establishment. In his history of this school, records the manner in which the young student, at the age of eighteen, attracted the notice of Lagrange by an improvement in the method of demonstrating the theorem which the latter had publicized in a lecture, and announced his intention of abiding by it for the future.

Poison never held any political situation, or took public share in anything but education. In 1829 he was named, by the emperor, director of the Ecole Polytechnique, member of the Council of Public Instruction, and of the Academy of Science. He died April 26th, 1840.

As far as so few words can go, it may be said that the Lhouis of Poison were directed to the introduction of the use of definite integrals in all branches of mathematical science, and the extension of the various branches by their means. There is nothing out of which to make a popular reputation; the successes of Poison are all purely mathematical, and not the mathematician can as much as understand the description of them.

The greater part of the writings of Poison are collected in various periodicals, particularly the Memoirs of the Institute, of the Polytechnic School, of the Academy of Sciences, and the Comptes Rendus, of the Société Mathématique, and the Connaissance des Temps, &c., &c. There is hardly any subject on which they do not treat, and almost always with decided success; electricity, magnetism, heat, geology, are the subjects of investigations, &c., &c., titles each of which suggests to the well-informed mathematician of our time the memory of some ably-written paper by Poison. His object was to leave no branch of physics unexplored by aid of the new and powerful methods of investigation which a school yet more modern than that of Lagrange and Laplace had added to the pure mathematics.

Towards the end of his life he began to collect his scattered memoirs into separate works, with the additions which his subsequent researches had given.

Poison's separate works are — 1. 'Tracté de Mécanique,' Paris, 1811, 2 vols. 8vo.; second edition, Paris, 1833, 3 vols. 8vo. Perhaps this is the best elementary work on a branch of mathematical physics which exists, considered as an introduction to the use of modern analysis. An English student should read it with some of our own writers, who abound in abstract ideas, and who have not the same facility of expression as the 'Theorie Mathematique de la Chaleur,' Paris, 1831, 4to. The principal distinction between this theory and that of Laplace, physically speaking, is the consideration of the variation of density which takes place at the end of the capillary column of fluid. '3. 'Theorie Mathematique de la Chaleur,' Paris 1831, 4to. The data from which Poison starts are derived from the experiments on the nature of heat, made subsequently to the time of Fourier, his object being to illustrate the effects of the capillary condensation by the graphs of the probability of the phenomenon of capillary condensation. '4. 'Oeuvres de M. Arago,' Paris, 1837, 4to. This is, in fact, a treatise on the theory of probabilities, with especial reference to its application to matters of evidence, particularly of the judicial kind. With the exception of a part of the integrals of definite integrals for series, there is little advance, mathematically speaking, upon Laplace; but the practical application of the science is, as before, made in new points of view. Accordingly, Poison has, with great judgment, made the application the heading of the whole work, though it occupies only the quarter of its space. It is said that Poison's second work nearly finished; but it has not yet been published.

POLANISIA (from polis, many, and ares, unequal; stamens numerous and unequal), a genus of plants belonging to the natural family of the Alstroemerieae, native to South America. The stamens are about 10 in number. The silique terete striated, rough with glandular horns, sessile and acuminate. It is native of the East Indies, and is used in Cochín China as a counter-irritant in the same way as sinapisms in Europe, and as a vesicant. The root is used as a vermifuge in the United States of America.

P. grandiflora is a plant beset with glandular hairs; it has trifoliate leaves, elliptic oblong leaflets, from 8 to 12 stamens, oblong siliques narrowed at the base, glandularly muriated and pubescent. It is native of North America, and is employed as a vermifuge.

The species of this genus are all annual plants from tropical countries: the seeds require to be sown in a banded hotbed, and when the plants are of sufficient size they should be planted out in the open ground. The best time for this should not be done before the middle of May. A plant of each should be kept in pots and placed in the greenhouse during the summer in order to secure seeds for next year's sowing. In the hot weather, the summer should prove favourable for ripening in the open border.

(Don, Gardener's Dictionary; Lindley, Flora Medic.) POLARIZATION. (Circular Polarization, F.C.S.; Elliptical Polarization, P.C.S.) POLARIZATION, MOVEABLE, is the name given by Biot to a supposed oscillatory movement of the molecules of polarized light in passing through a plate of doubly refracting crystal; and the hypothesis was proposed in order to account for certain variations of tint observed in the coloured images produced by the ordinary and extraordinary pencils of light. This philosopher assumed that, in permanently polarized light which has been transmitted through a doubly refracting medium, the molecules composing the ordinary pencil or ray have their axes at right angles to those of the molecules which compose the extraordinary pencil, and that M. Arago having observed that the tints of the two images formed after the transmission of a pencil of polarized light through a plate of sulphate of lime varied with the thickness and position of the plate, supposed that the rays were transmitted into the plane of the plate whole at a right angle to the image and the green or violet rays into the other, while at other angles of incidence the contrary phenomena occurred, — he was led to imagine that the polarized pencil, after having entered the plate, does not assume the character of permanently polarized light till it has penetrated to a certain depth, depending on the degree of attractive or repulsive power to which the particles are subject in the medium; and he conceived that, previously to being in that state, the axes of the molecules assume, in a series of alterations, first one and then the other of two particular planes of polarization.

This reasoning then that the phenomena of the colour seen in polarized light are analogous to those of Newton's rings, the ordinary and extraordinary rays giving rise to colours corresponding to those of the rings seen when transmission and reflection occur; the refraction and reflection making the rays from the plate and the incident rays pass through the plates, and reflexions and refractions take place alternately at intervals between the plates which, for homogeneous light of any colour, are comprehended between the terms in the series of distances 0, e, 2e, 3e, &c. In the passage of light through the plate of sulphate of lime, the alternate polarizations take place at intervals equal to those between the terms in a corresponding progression; between these intervals being, however, much greater than the distance of the chief to the second. In the term of 4e the depth represented by e in the crystal, the molecules are conceived to be polarized in the original plane of polarization; between the depths represented by e and 2e they are supposed to be polarized in a plane making with the original
plane of polarization an angle equal to that which the two axes of the biaxial crystal make with each other; within the next depth, that is between 2′ and 3′, they appear to be again polarized in the plane, and so on.

In the same kind of crystal the values of ε are supposed to differ for the different kinds of light, but the limits of the oscillation are the same for all particles whose motions are in the same direction of the incident light. The case when the luminous particles hit the posterior surface of the plate and pass into the air, or enter into any other medium which has not the property of double refraction.

The phenomena presented by mice, beryl, rock-crystal, Iceland spar, and many other crystals, are the same as those presented by sulphate of lime, except with respect to the thickness at which the periodical variations of the tints take place; and this property is generally capable of quantitative determination, but in the hypothesis of a movable polarization: the oscillations, however, do not take place on each side of a line bisecting the angle between the two axes of the biaxial crystal, but on each side of the plane towards which the axes of the particles in the pencil ordinarily refracted by the plate would be turned if those particles had acquired a permanent polarization.

Though Biot's hypothesis of movable polarization has been found capable of explaining most of the phenomena of polarized light, both that in which the incident pencil consists of parallel rays and that in which, the rays being convergent, coloured rings [Polareized Rins, P. C. S.] are produced, yet it is known to be tenable in many respects: The difficulty of the placement of the plane of polarization in plates of crystal may be satisfactorily explained on the principles of the undulatory theory: thus, suppose a polarized ray to be incident perpendicularly on a crystalline plate having its principal section inclined to the plane of primitive polarization in a certain angle; that ray will then be resolved into two, the vibrations of the aetherial molecules in which are respectively performed in the principal section and perpendicular to it. Now, if the thickness of the plate be such as to render the difference between the lengths of the paths of the rays within the crystal equal to an exact number of vibrations, the rays will emerge from the plate in exact accordance: in this case the ordinary and extraordinary rays being polarized in opposite planes they will not destroy each other, and it will be found that the resultant ray, at emergence, is, in respect of intensity and polarization, similar to the incident ray. But if the difference between the lengths of the paths within the crystal be an exact odd multiple of half an oscillation, the waves at their egress will be in discordance, and the resultant ray, at emergence, will be plane polarized in a plane making an angle with the plane of the incident ray equal to twice that at which the principal section of the plate is inclined to the plane of primitive polarization.

POLARIZED RINGS. Between the years 1812 and 1816 several important properties of polarized light were discovered by philosophers in England, France, and Germany, and of these the formation of the coloured rings which are seen when polarized light is transmitted through plates of a doubly refracting crystal, are the most remarkable.

As early as 1811 M. Arago and Biot had observed the variations in the colors of images, which take place when polarized light is transmitted through plates of mica, having made similar observations with agate, mica, and topaz. But the British philosopher vastly extended this branch of optics by his discovery of the systems of rings, which may be seen by both eyes and uni-axial crystals when conical pencils of polarized light are transmitted through them; and his experiments, with those of Young, Wollaston, and Sir John Herschel, in England, have afforded materials for the determination of the laws of the phenomena.

In 1813 Brewster observed circular rings in ruby, emerald, and beryl; in the following year the like were witnessed by Dr. Wollaston in Iceland spar and in 1815 they were seen by M. Biot in France and by Dr. Scheel at Nürnberg.

In order to understand the manner in which the phenomena may be observed, it will be convenient to imagine that the light is polarized by means of a plate of glass either parallel or inclined to the horizon; (a plate of obisism or a pile of glass plates placed one on another may be employed) its posterior surface being blackened; and let the surface of a second plate of glass having its posterior surface also blackened. The former is called the polarizing and the latter the analyzing plate. Let AB be the axis of a slender pencil of light from the clouds or from a lamp surrounded by an unpolished glass, and let it fall on MN at an angle of incidence equal to 58° 47′, the reflected pencil, of which let AB be the axis, will then be polarized in the plane of reflection SAB, which may be called the plane of primitive polarization; and in this state it let it fall on PQ at an angle of incidence of 90° from B let it be reflected to the eye of the observer, suppose at C. The plate PQ should be attached, as in the figure, to the surface of the block FM. PQ; and, for convenience, let the block be a triangular prism of which the plane PD is horizontal and the plane EDQ vertical: the block should be capable of being turned on an axis as BF in the direction of the ray AB produced.

According to the hypothesis of Fresnel the vibrations of the aetherial molecules, when light is polarized, take place perpendicularly to the plane of polarization; therefore, if the plates MN and PQ are disposed as in fig. AB, the course SABC of the ray is in one plane (supposed vertical) and no object is placed in the direction of the pencil AB, the vibrations will take place after reflection from PQ, exactly in the same manner as they take place between the mirrors, and the spectator will have a strong perception of the reflected light. But if PQ be turned on the axis ABC, the perception of the reflected light diminishes; and when the base PD is perpendicular to its first position, in which case the plane SAB and ABC are at right angles to one another, the vibrations are destroyed in consequence of a polarization with respect to the plane ABC, so that the eye at C has no perception of reflected light.

Now, let a thin plate of Iceland spar, ruby, emerald, or other uni-axial crystal cut with parallel surfaces, each perpendicular to the axis of the primitive crystal, be placed as at IK in the direction of the polarized pencil; the former state of the pencil BC will be partially restored; and an eye at C receiving the pencil through a small aperture, there will be seen in the field of view a number of concentric circular rings of different colours, two of which are always visible; one has its branches at right angles to one another. When the phenomenon is observed with common white light polarized as above said, the centre of the field is occupied by a black spot surrounded by a deep blue colour, which gradually declines to whiteness; and, proceeding from the centre outwards, the colour becomes successively a pale yellow, orange and deep red, similar to the first series of Newton's rings. [Colocass or Plates, P. C. S.] The colours in the succeeding rings are arranged in the like order till the rings cease to be perceptible, the cross remaining black.

The phenomena may be observed with equal or greater facility by placing the plate of Iceland spar or other crystals between two plates of tourmaline parallel to each other and to the plate of spar, and observing the lights directly through them; the plate of tourmaline which is farthest from the eye polarizes the light transmitted through it as the plate MN (Fig. 1) polarized it by reflection; and the plate nearest to the eye, having its axis perpendicular to that of the former plate, performs the same office as the analyzing plate PQ, when the surface of the latter is perpendicular to MN. The plates of tourmaline should be cut with their surfaces parallel to planes passing through, or parallel to, the axis of the natural prism; and what is called the axis of the plate is any line drawn on either of its surfaces parallel to the axis of the prism.

In 1813 Dr. Brewster observed that certain crystals, when polarized light was transmitted through them, exhibited two distinct systems of rings; and his first observations were 3 K 2
made on blue tints: a plate of this mineral being placed, as at IK (Fig. 1), and the analyzing plate PQ, being turned round, PD was in a vertical position, that is, till the plane ABC was at right angles to SAB, there appeared a system of rings, apparently elliptical with a rectilinear band quite dark in the direction of the major axis: the colours of the rings being corresponding with those of Newton's rings when seen by refraction. By turning the plate PQ on BF as an axis 90° further, or 180° from the position in the figure, the series of rings appeared with colours seemingly complementary to those of the former series, or, apparently similar to those of Newton's rings seen by transmission. But, turning the plate PQ on an axis BF perpendicular to BF in the plane SAB of primitive polarization, there was found a position in which, by the reflected ray BC, there was seen a system of oval rings similar to the first.

Dr. Brewster observed the like phenomena with plates of mica, nitre, sulphate of lime, &c.; and this led to the discovery that, in such crystals, there are two axes along which there is no double refraction. These are the optic axes of the crystal, or, as they were called by Brewster, axes of no polarization. In different crystals these axes have different inclinations to one another; in micas they make with each other an angle of 45°, in nitre much less; and a plate of crystal cut for the purpose of exhibiting the double system of rings should have its faces cut perpendicular to a line bisecting the angle formed by the optic axes.

Now, if a plate of any bi-axial crystal, as mica, nitre, &c., be placed as at IK in the direction of the polarized ray, and be turned so that one of the optic axes is coincident with that ray; the analyzing plate PQ (Fig. 1) being also turned so that the reflected ray BC may be in a plane at right angles to SAB, there will be seen, about a dark point P (Fig. 3), representing in that which the axis intersects the field of view, a series of oval rings brightly coloured and divided unequally by a dark band MN. A like series of rings about a point corresponding to P, with a dark band like MN passing through that point, will be seen if the plate of crystal be turned so that the other optical axis is in the direction of the polarized ray AB. And when the angle which the optical axes make with one another, or with a perpendicular to the surface of the crystal, is small, as in nitre, both series of rings with their bands may be seen at the same time.

When a plane passing through AB (Fig. 1), and the two optic axes of the crystal are made, by turning the plate of crystal on the ray AB, to coincide with the plane SAB of primitive polarization, the dark curves passing through the two poles points P and P' (Fig. 4) become one straight line MN; the coloured rings come together as in the figure and are crossed by another dark line as M'N' passing through B theore; at right angles to the former. This appearance takes place at every quarter revolution of the crystal plate IK (Fig. 1), on the axis AB; and by actual determination, the coloured rings are found to have the form of lemniscates, whose properties are that the product of two lines drawn from the points P and P' to any point in each curve is constant.

The general equation of Bernoulli's lemniscate is

\[(x^2 + y^2)^{3/2} = a^2(x^2 - y^2)\]

in which \(a\) is equal to half the axis \(a\) of the particular curve, and \(x, y\) are rectangular co-ordinates of any point as \(P\) on the curve, \(B\) the centre being the origin. If BF or BF' be represented by \(a, a'\), and be homogeneous to \(a', a\), the product of two lines as \(PP, PP'\) (not drawn in the figure) will be equal to \(a^2\). But, in order to allow B P to be constant for all the different curves, the equation may be put in the form\(x + y\) being equal to \(a\), in which \(b\) may be of any magnitude whatever from zero to infinity; and from this equation the value of the rectangle \(PP, PP'\) for any one curve is the product \(ab\).

In explaining the phenomena of polarized rings on the undulatory hypothesis, it is assumed that a pencil of polarized light, in its passage along the axis, or along one of the axes of a doubly refracting crystal, ceases to have its ordinary and extraordinary rays polarized in planes at right angles to one another, in consequence of the different degrees of retardation which the waves in the two kinds of rays experience in passing through the crystal, so that they emerge from it in different (those vibrations alone producing a perception of light in the eye, which are perpendicular to the plane of polarization) the angle between that plane of polarization and the plane of primitive polarization being represented by \(a\); a resolved vibration in the ray R, therefore, is produced by the double refraction of the crystal becomes

\[\cos \theta \cos (\theta + a) \sin \frac{2\pi}{\lambda} \frac{a + a'}{\sqrt{2}}\]

and, for the extraordinary pencil,

\[\sin \theta \sin (\theta + a) \sin \frac{2\pi}{\lambda} \frac{a - a'}{\sqrt{2}}\]

Developing \[\sin \frac{2\pi}{\lambda} (a + a')\]

and then adding together the squares of the coefficients of \[\sin \frac{2\pi}{\lambda} \frac{a + a'}{\sqrt{2}}\]

\[\sin \frac{2\pi}{\lambda} \sin \frac{2\pi}{\lambda} \frac{a + a'}{\sqrt{2}}\]

is, by the undulatory theory, an expression for the intensity of light in the image, at a point where the apparent field of view is intersected by a ray whose inclination to the axis AB (Fig. 1) enters into the expression for R; the plane passing through such ray and the axis AB making with the plane of analysis a variable angle equal to \(\theta + a\). Putting \(\psi\) for \(\theta + a\) the above expression has the form

\[\cos \psi \cos (\psi - a) \sin \frac{2\psi}{\lambda} \sin \frac{a + a'}{\sqrt{2}}\]

and, when \(\psi = 90°\), or the planes of polarization for the rays AB and BC are perpendicular to one another, the last expression becomes

\[\sin \frac{a + a'}{\sqrt{2}} \sin \frac{2\psi}{\lambda} \frac{1}{R}\]

where the length \(L\) of a wave differs for the different kinds of light, but the conclusion arrived at being independent of any particular value of \(\lambda\), it follows that all the light vibrates when \(\psi = 90°, 180°\) and \(270°\); consequently there are at the same
time two lines or bands traversing the coloured field of view at right angles to one another, in which the light vanishes; and thus there is produced the appearance of a dark cross, the point of intersection being in the centre of the field, or where the bands traverse one another.

When \( s = 0 \), or the planes of polarization in AB and BC are coincident, the expression (c) becomes

\[
\sigma (t = \sin \phi \sin \phi = \frac{R}{K})
\]

(c) which when \( \phi = 0^\circ, 90^\circ, 180^\circ, \) and \( 270^\circ \) becomes \( \sigma \), a maximum; hence the coloured field of view will be traversed by a white cross with arms at right angles to one another.

If \( s \) have other values, the expression (b) or the density of light will vanish when \( R = 0 \), for \( s = 0, \) \( \alpha = \alpha, \) \( \alpha = 2\alpha, \) &c. But the equivalent of \( R, \) containing, as a multiplier, \( \sin \phi \), (b) being the incidence of a ray on the crystal after diverging from A, or the angle which, as above mentioned, a ray from A makes with the axis AB one giving successively to \( R \) the values \( 0, \) \( 2\alpha, \) &c., it is found that \( s. \) has corresponding values proportional to \( \sqrt[4]{s}, \sqrt[5]{s}, \sqrt[6]{s}, \) &c.; (T being the thickness of the plate of crystal) and since the expression (b) has the same value, and vanishes or is a maximum, for all rays whose angles of incidence in the conical pencil diverging from A are the same, it follows that, about the axis of the field of view, there is the same maximum for all rays whose radius of divergence from A is \( \sqrt{s}, \sqrt[4]{s}, \sqrt[5]{s}, \) &c. The expression (a) is a maximum when \( R = \frac{1}{2} \alpha, \frac{3}{2} \alpha, \frac{5}{2} \alpha, \) &c., or when \( s \) has values proportional to \( \sqrt[4]{s}, \sqrt[5]{s}, \sqrt[6]{s}, \) &c.; and it follows that, about the axis of the field, there is a series of bright rings whose radius have the proportions of \( \sqrt{\alpha}, \sqrt[4]{\alpha}, \sqrt[5]{\alpha}, \) &c.

For the investigation of the phenomena of the rings seen (in Fig. 4) when 1K is a bi-axial crystal having its surfaces cut perpendicular to the plane passing through the axis; and also for the phenomena presented when a plate of crystal, uni-axial or bi-axial, is so cut that the surfaces are not perpendicular to the axis, or to the plane passing through the two axes, see Airy's Tracts (Undulatory Theory). The reader is referred also to Sir David Brewster's Treatise on Optics in the Edinburgh Encyclopedia, and to Sir John Herschel's Fragments on Optics.

**POLLEMONIUM** (polystemon of Dioscorea), a genus of plants, the type of the natural order Pollemiacaeae. It has a campanulate 5-chiefed calyx, a rotary corolla, and a short tube with a 5-sided oral segment. The 5 equal stamens inserted in the throat of the corolla with filaments dilated at the base, bearded in a continuous ring, and nearly closing the throat, and incumbent anthers; the filaments cylindrical, crowned with numerous crumaceas valves, covered with the permanent calyx and many-seeded cells; the seeds oblong, trigonal, and filled with albumen; the radicle twice as long as the cotyledons. The species are erect herbaceous plants, with alternate unequally pinnate leaves; the flowers terminal, bracteated, arranged on panicled corymb, with blue or white corollas. About twelve species have been described, most of them being cultivated and known in our gardens as *Crock* Valley. *F. carafius*, common Greek Verlani, Jacob's Ladder, or Ladder of Heaven, has a glabrous stem, pinnate leaves, ovate lanceolate acuminated leaflets, the segments of the calyx ovate or obtuse, lacinolate, pointed; the petal downy, glandular. The stem is one or two feet high, the leaves alternate, the flowers numerous, bright blue or white, somewhat drooping. It is a native of Europe and America, and is found in Great Britain, but is a rare plant. A great number of varieties have been described. It is a favourite plant in our gardens, and will grow in any common garden soil, and may be readily propagated by dividing the root or by seed. Although it is known as a Pollemium of Dioscorea, it does not appear to agree at all with his description of that plant, and *Frass* refers it to Hypericum olympicum. Great virtues were attributed to the ancient Pollemonium, and these were transferred to the modern plant; but neither the ancient nor modern plant possesses any active medicinal properties. Slight property of Pollemonium is the only property possessed by any of the species of Pollemion.

**POLICE.** In Scotland the larger towns have separate police statutes, by which the management and control of the system is put into the hands of elected commissioners. The Police Acts 1834 & 4 Wm. IV, and the Acts relating to the police of commissioners of powers of management and control, are the same as those of the police of Lorenzo Ghiberti, and assisted him in the celebrated gates of the baptistery of San Giovanni; he became also a famous goldsmith, and was at such as much, or superior, or Florence; Maso Finiguerra was his contemporary and the two brothers generally cooperated in their paintings together; the best of them, says Vasari, is the Martyrdom of St. Sebastian, painted in 1479, in the church de' Servi at Florence. St. Sebastian was painted from nature and is one of the best portraits that had been painted up to that time; it is engraved in the *Etruria Pitrice di Lustrai*.

Antonio is said to have been the first artist who studied the dead subject for the purposes of design. Antonio Pollaioolo was invited to Rome in 1448, after the death of Sistine IV, and of Innocent VIII. In 1449, he made the monuments of Sixtus IV., and of Innocent VIII.; that of Sixtus, in 1493, is now in the church of the Sacrament in St. Peter's; the monument of Innocent is also in St. Peter's. Antonio was also a medalist, and he engraved three or four plates, which are extremely scarce.

(Vasari, Vite dei Pittori, &c., and the notes to Schorn’s German translation; Rubnroh, Italianische Forschung; Cicozrara, Storia della Scultura; Baldinucci, Notizie de Professioni dei Dignaz., &c.)

**POLLAIOLO, SIMONE DEL, or Simon Masi, a distinguished artist, generally called II Cronaca, from his ability in relating stories, was born at Florence in 1454. He was related to Antonio del Pollogajo, and lived with him some time at Rome. He was chiefly distinguished for the Palace of S. Maria della Strozzi, one of the most ancient buildings in Florence; it was commenced in 1489 by Benedetto da Maiano, but was completed by Cronaca, and the great cornice or entablature and the court in the interior are from the designs or engravings of Cronaca. The ironwork and the beautiful lanterns are by Niccolo Grosso, commonly called Caparra, a nickname which was given to him by Lorenzo de’ Medici on account of his always persisting in being paid before he delivered his work: Caparra signifies deposit or advance-money. Grosso was the most celebrated smith of his time.

Cronaca built also the great council-hall for the Signoria of Florence, which was afterwards enlarged and embellished by Vasari; the church of San Miniato al Monte, the presentation necessary for him for a charge in the United Secession Church, of which he became a licentiate in 1827. His principal work, which is in some respects auto-biographical, speaks of the solitude and pastoral simplicity of the scenes in which he passed his youth.
He was a hard student, and appears to have been early en-
dowered with a strong ambition to create for himself a per-
manent name in literature. In his own words—

"This page he tore, and read it a second time, a third, and a fourth, and the eleventh, and the hundredth, and the thousandth, and the millionth page. He was not satisfied with reading; he was determined to conquer, to conquer the whole, and to conquer the world."

Just before he received his licence, he had finished the poem on which his literary reputation rests, "The Course of Time." A work so ambitious, from the hands of a country student, that it was likely to be the first composition of a small body of discourse to be in a position to find a patron among publishers. It happened to be shown to Professor Wilson, of Edinburgh, as a curiosity, and he was astonished to discover in it great poetic power. In deference to his recommendation it was published by Mr. Blackwood, of Edinburgh, and speedily passed through several editions. Its flight of genius was a novelty in the class of evangelical religious literature to which it belonged, and besides pleasing those who are partial to that class of religious literature, it was a boon to many who are inclined to read religious books, but are repelled by their general dryness and insipidity, while it was warmly admired by the literary world. Mr. Pollok's publishers expected him to find a place on a level with Milton. After the novelty of such a phenomenon had however passed off, the book became neglected by purely literary readers; and at this day it may be said that it is hated too highly by the literary world to be insignificantly by the literary world. It is a work of great power, but meagre fancy. It has a considerable amount of sentiment deeply tinged with religious asceticism. Many sentimentalities are spun out or repeated, and the interest frequently flags. The work exhibits a great command of the English language and a power of terse rapid melodious diction. Pollok's mind was evidently imbued with "Paradise Lost," and he followed Milton often to the verge of plagiarism. But the publication of his poem this interesting young man had undermined his constitution by excessive mental labour, and he scarcely lived to see its success. On the recommendation and through the assistance of his friends he was preparing for a journey to Italy. The simplicity in which his family was brought up, may be imagined from the circumstance that his sister, who was to accompany him, obtained a certificate of good character from the minister and elders of her parish, believing that such a testimonial was all the more necessary as they were about to proceed to 'the land of graven images.'

The disease had however made too great progress to admit of his leaving Scotland, and he died near Southampton on 15th September, 1837.

**POLYCARPIDON (from σῶλος, many, and ἀφρος, a seed or fruit: seeds numerous), a genus of plants belonging to the natural order Poly-
carpidae.**

**POLYGNUM (the Greek σωλογνός, 'much-produ-
cive'), a genus of plants belonging to the natural order Poly-
carpidae.**

**P. obtusifolium,** an inhabitant of Europe, the Cape of Good Hope, and Holland; and **P. peploides**, a native of Sicily and France. The seeds of the annual species require only to be sown in the open border in spring. The last species, being perennial, should be grown in a small pot, and placed among other alpine plants.

(The Botanist's Manual; Dictionary of Botany.)

**POLYIODIUM (Fuerst, P. C. S.)**

This plant is an ally of Castanea. It is of British Botany.

**POLYPOGON (from σωλοτρικός, a beard), a genus of grasses belonging to the tribe Agrostideae.**

It has several nearly equal glumes, each furnished with a long seta from just below the emarginate palea. The palea are shorter than the glumes, the outer ones usually curved from below the summit.

**P. monopetalum** has the setae more than twice as long as the rather obtuse glumes. It has a fibrous root, a stem from a foot to foot and a half high, a dense lobed silky panicle often two inches long. The glumes are linear and hairy. It is a very beautiful grass, and a native of Great Britain in salt marshes. It is the *Equisetum* (fox-tail) of Theophrastus, *Hist. Plant.* 7, 17.

**P. littorale** has its setae equalling the acute glumes. The root is somewhat creeping, the stem about a foot high, the panicle close lobed and purplish. The glumes are linear lanceolate. It is a British species and is found in muddy salt marshes.

(Babington's Manual of British Botany.)

**POLYTECHNIC SCHOOL.** This institution was established in London in 1823 to provide extensive and practically useful attainments in pure and applied sciences, originated by the time of the great revolution in France, with one of the representatives of the people, named Fleur (de la Côte d'Or), who being a member of the Committee of Public Safety, and charged with
the duty of superintending the practice of the arts which relate to the service of the country, introduced a plan for the establishment of the school to one of the particular committees which had been appointed by the National Convention. In consequence of a report made by Fourcroy in the name of three united committees, and under the designation of 'École centrale des Travaux publics,' was, by a decree of the Convention, dated 21 Ventose, An II. (Feb. 18, 1794), directed to be formed; and the charge of organizing it was assigned to Moreau, who had been appointed for the post of Gauty Moreau: the first, in particular, was appointed to determine the branches of science which were to constitute the course of study.

The school was to consist of 400 pupils, who were to be admitted on undergoing, satisfactorily, an examination respecting their knowledge of the elements of arithmetic, algebra, and geometry; and, after retaining three years at the institution, during which time they were to be instructed in the higher branches of mechanical science, they were to receive appointments for the posts of civil or military engineers. The course of instruction was divided into two principal branches: the first consisted of mathematical analysis with its applications to geometry and mechanics; and to these were added a course of descriptive geometry [Morgan, P.C.], which was again present before the students. The second branch consisted of chemical and natural philosophy. A building in the Rue Ste. Geneviève was chosen, and the students were divided into classes, each consisting of from 20 to 30: the classes were to be held in a separate hall, during six hours of the day; at certain times, however, they attended lectures in the theatre of the institution; and on two days in every ten they were employed in performing experiments in the chemical laboratory. The pupils were required to execute all drawings relating to the subjects of their studies, and to perform experiments with their own hands, conformably (as is stated in the programme) to the methods followed in the school founded at Metz, for military engineers, and in the school of chemistry and mining at Schenmitz in Hungary.

Such was the origin of an institution of which, with respect to both the branches of instruction to which science has received from so many of its élites, France may be justly proud; and it is worthy of remark that it was formed at a time when some of the most influential men in the government of the country proposed to put all the learned men to death, and to annihilate science as being inimical to the interests of the new republic.

Outlines of the lectures delivered by the professors during the first year were published in 1796 in a volume forming the first of those which constitute the 'Journal de l'École Polytechnique'; and among these are one on stereotomy, by Monge, on architecture by Balian, on fortification by Dopen-heuser, by Nivois, on chemistry by Fourcroy, and on analysis by Prony.

In the course of the same year, 1796, the National Convention decreed that the 'École centrale des Travaux publics' should be opened, and new regulations were made concerning the subjects in which the candidates for admission were to be examined. In mathematics there was required a knowledge of algebra, as far as the resolution of equations of the fourth degrees, with its application to geometry; the summation of series; trigonometry and the properties of conic sections. For the convenience of persons residing in the provinces, the examinations for admission to the school were appointed to be held, at the same time, at towns situated in different parts of France; the municipal authorities of the towns were to be requested to conduct such examinations; and the candidates were to be conducted by duly qualified persons, to be appointed for the purpose. A youth between 16 and 20 years of age only was admissible; and before a candidate was allowed to present himself for examination he was required to exhibit a certificate of good conduct, and of his attachment to republican principles; or, as the sentiment was sometimes expressed, his love of liberty and equality, and hatred of tyrants. A successful candidate was afterwards stationed in a particular military establishment, the Royal Engineers at Paris, on an appointed day: an allowance of money equal to that which was made to a private artillery-man of the first class being assigned to him for his travelling expenses; and, during the time of his residence in the institution, to receive, or, if necessary, to pay, 1200 livres (50l.) yearly. Three years were considered as the time necessary for the completion of the appointed course of study; and a student was not, under any circumstances, to remain at the school longer than four years. Public examinations were to take place at the end of each year; and pupils who should not be found to have attained the requisite proficiency in at least three-fourths of the subjects constituting the prescribed course of education were to be withdrawn from the institution.

In the following year (1796) the National Convention decreed the formation of eight special schools for instruction in matters concerning the different professions which relate to the public service: viz. those of Metz, for Engineers of Metz; those of Arcis, for Engineers of Arcis; those of Châlons; those of Engineers of Metz; those of Ponts et Chaussées, for Bridges and Roads; those of Mines, for Engineers of the mines; those of Marine, for Engineers of the navy; and the students in all these institutions were to receive salaries from the state.

A student desiring of serving the country in any one of the professions for which the special schools were appointed, might, after being two years at the Polytechnic School, become a candidate for that particular profession; and if, after examination, he was found qualified, he was either admitted in the special school or was, on a vacancy occurring, appointed immediately to a post in the department to which he was assigned.

An unsuccessful candidate might remain at the Polytechnic School during the third year; and, at its expiration, he might then present himself as a candidate for the Polytechnic School. Any candidate was to exercise the functions relating to any particular department of the service was also allowed to remain during the third year at the Polytechnic School, in order that he might complete his course of study; and, on the third anniversary of the government of the school being placed under the direction of the minister of the interior; and it was the duty of that minister, under the Executive Directory, to assure himself that the regulations of the school were in force; but the number of students was, at the same time, reduced to 300.

At the end of the first year, 40 young men were taken from the school to serve as officers of engineers; and these officers were to be selected from those who had been admitted to the Polytechnic School as military engineers, and several were appointed to posts in the other special schools.

The necessity of having during teachers for the purpose of preparing the junior pupils, or such as required more detailed instruction than could be afforded by the professors, led, in 1796, to the appointment of assistant preceptors; and these were selected from among the students who, having completed their course of education, were qualified to perform that duty: at the same time, also, the students were made to wear a military uniform. It is remarked that Bonaparte, after his return from the campaigns in Italy, often visited the institution, where he took pleasure in encouraging the youths to prosecute their studies; and when he sailed on the expedition to Egypt he took with him twenty of the most advanced pupils; he was also accompanied, in that expedition, by Monge, who was the principal professor.

In the year 1800 the school was re-formed and the number of students was reduced to 300: the mathematical course was increased; and it was then that a number of new regulations were made concerning the admission of pupils in the armies of the republic during three years should be admissible till they were 26 years of age. The pupils, in general, had then the rank of sergeants of artillery, and their daily pay was 98 cents (46 pence). The military uniform was continued, and on the margin of the buttons were the words 'École polytechnique'; some alterations were made in the mode of conducting the examinations; and a council was appointed for the purpose of attending to the state of the school, and also of suggesting measures for its improvement.

When Bonaparte became emperor, in 1804, the school was again remodelled, and Monge was replaced at its head; it then acquired the title of 'École polytechnique impériale,' and it received an organization completely military. While that extraordinary man governed France the institution may be said to have been in its most honourable period; and the subjects of the course of study were then arranged under thirteen heads, as follow:—Mathematical analysis; mathematical analysis applied to geometry; descriptive geometry; mechanics of fluids; machinery; mechanics of solids; electricity; magnetism; topography; the military art; architecture; drawing of figures and landscapes; grammar and the belles-lettres. At that time also, the following were the subjects a knowledge of which was required of all students: the philosophic, with an explanation of the metrical system. 2. Algebra, containing the resolution of equations of the two first degrees — indeterminate equations of the first degree—the composi-
tion of equations—demonstration of the binomial theorem—
the method of indeterminate divisors, and that of equal
roots of equations. All these are necessary elements of
algebra— and the elimination of unknown quantities in equations
of any degree having two unknown quantities. 3. The
theory of proportion—progressions and logarithms. 4. Ele-
mentary plane trigonometry and the course of descriptive geometry. 6.
Discussion of lines represented
by equations of the first and second degrees with two
unknown quantities—the principal properties of conic sec-
tions. 7. Statics demonstrated synthetically and applied to
the equilibrium of simple machines, as the lever, wheel and
axle, &c. 8. The candidates were also required to translate
part of a Latin author in prose, and give a grammatical ana-
lysis of the sentences. 9. To compare, with scale and
compasses, any geometrical figure which the examiner
might indicate. And 10. To draw and shade, with pencil, a
figure from a given model.

In 1814 the students of the school took a share in the
defence of Paris, and even assisted in serving the guns
directed against the allies. On the restoration of the Bourbon
family, the school was for a time suppressed; but it was
afterwards revived, and it then received the title of "Ecole
Royale Polytechnique," which it still retains. Occasionally
since, unmindful of the submission due to the government
which educates them, the students have, as in 1816 and 1830,
united themselves to their former opposition to the govern-
ment's measures: the acts of insubordination which took place in
1845 appear to have originated merely in a dislike which, for
some reason, the students entertained to a person who had been
present at the examinations; the acts were violent that the king, Louis-Philippe, entirely suppressed the
institution. It has, however, again been revived, and, except
a few of the most culpable, all the students have been
readmitted.

The object of the Polytechnic School is still the same as
at its formation; and the young men are educated for the fol-
lowing branches of the public service: viz., the artillery of
territory; the military engineering; the navy; the marine
technique; the cooperation; the county inquests; the
government of the sea; and the navigation of the seas.

The number of students is now reduced to 200, and the
duration of the course of instruction is two years. Each
student subscribes annually 1000 francs (41l. 13s. 4d.), and
the expense of his clothing is, in addition, about half that
sum. The commander-in-chief of the French armies is the
head of the institution, and all the students are subject to
military law. A candidate for admission must be a native
of France, or a naturalised subject of the kingdom, and he must
be between sixteen and twenty years of age. There are,
however, admitted till the age of twenty-five; but they
cannot receive leave of absence, to prepare themselves for the
examination, till they have been two years with their regi-
mental colleagues.

The government does not engage itself to receive in its
employ all the young men who have been educated at the
school: but such as pass their final examination are allowed,
some of the ranks of merit which were awarded to them by
the jury appointed to decide respecting their qualifications,
to enter one of the branches of the public service as far as
the vacancies will permit. In the gift of the Minister de la
Marine there are four scholarships, in that of the Ministre de l'Intérieur eight, and in that of the Ministre de la
Guerre twelve; and these are for the benefit of youths whose parents
or guardians are unable to pay the subscription. They are
called 'places gratuites,' and each year is equivalent to two
places, which are distributed by the jury, the admittance to
which is decided by a public examination, in which the
students are required to execute a piece of work in one of
the branches of knowledge, as well as a difficult examination
in knowledge of the subject, in which there is an opening
for the young men to show their powers and acquirements.

The 'Journal de l'Ecole Royale Polytechnique' continues
to be published by the 'Conseil d'Instruction,' and it contains
notes on the results of researches relating to the highest
branches of mathematical science. The principal papers were
contributed by La Grange, Monge, La Place, Poisson, Prony,
and other celebrated men; and those of more recent date are
written by the able mathematicians of France, several of
whom have been prizemen of the institution.

PO'MÉE, a section or sub-order of the natural order of
Rossmum. [Rosacea, P. C.] The following is a synopsis
of the genus Rossmum.

1. Cratoxylum (epiherav). Calyx uncoate, 5-cleft;
petals orbicular; ovary 2-5-celled; styles 2-5, glabrous;
the fruit fleshy, ovate, containing a bony putamen. [Crato-
xmlum, P. C.]

2. Raphoelepsia (from man, a needle, and xele, a scale).
The limb of the calyx funnel-shaped, deciduous; the ovary
2-celled, 2-styled; the fruit with a thickened closed disk,
and a papery putamen containing 5 globulous seeds.

3. Chamaemelum (from cham, the ground, and melon, an
apple). Calyx truncate, with 5 little teeth; the petals small,
cease; the stamens 10-15; the ovary 1-celled; the style
5-cleft; the fruit united to the calyx. [Chama-
emelum, P. C.]

4. Photinia (from phairn, shining). Calyx 5-toothed;
petals reflexed; ovary villous, 2-celled; styles 2, glabrous;
fruit 2-celled inclosed in the fleshy calyx.

5. Eriobotrya (from tribe, wool, and phlauros, grape).
Calyx woolly, 5-toothed; petals broad; styles 5, pilose,
inclosed; fruit closed, 5-celled.

6. Cotoneaster. Flowers polygamous; calyx turbinate,
bluntly 5-toothed; petals short; stamina length of the
calyceal teeth; styles glabrous, shorter than the stamens;
2-3 carpels, parietal, inclosed in the calyx with 2 ovules. [Coto-
neaster, P. C. S.]

7. Acorus. Calyx 5-cleft; petals lanceolate; stamens
shorter rather than the calyx; ovary of 10 cells or 5 binate
cells with one solitary ovule in each partition; styles 5,
joined at the base; fruit 3-celled; seeds 5-5; the endocarp
carillaginous; the calyx inclosed in the achene. [Acorus,
P. C. S.]

8. Mesolisla. Calyx 5-cleft; segments foliaceous; petals
nearly orbicular; disk large, filled with honey; styles 2-5,
glabrous; fruit turbinate, open at the apex, 5-celled—
endocarp bony. [Mesolisla, P. C. S.]

9. Oestosmisia (from sericus, a bone, and melon, an apple).
Calyx 5-toothed; petals oblong; styles exerted, the same length
as the stamens, bearded below; ovary 5-celled; cells 1-seeded;
fruit closed, bony. [Oestosmisia, P. C. S.]

10. Pyrus. Calyx uncoate, 5-lobe; petals roundish;
styles usually 5, rarely 2 or 3; fruit closed, 5-celled; cells
carillagious; seeds 2 each in cell. [Pyrus, P. C.]

11. Cynodora. Calyx 5-cleft; petals orbicular; styles 5;
fruit closed, 5-celled; cells carillagious, many-seeded; seeds
covered with pulp.

The species of the genus Raphoelepsia are known by the
same of Indian Hawthorn. They are natives of various
parts of Hindustan and China. There are six species of this
genus, four of which have been cultivated in this country,
and introduced as species of Cratoxylum or Mesolisla.
These are—

P. indica. Common Raphoelepsia, a native of China; R. rubia, a native of Cochinchina; and
R. nolisba, a native of China. All the species are trees in
their native climates, with evergreen crassate cortical
rachises, and flowers in terminal racemes, with white
petals, and red stamens. The species will grow well in a
mixture of sand, loam, and peat. R. Indica, in British
gardens, is an evergreen shrub blossoming from February to
August, and a large number of the species have thus
been awarded to us for many years. It is probable all the species would bear our winters if
planted against a south wall, and covered with mats in
severe weather.

The genus Chamaemelum was constructed by Lindley for a
single species, C. coriaces, which is found in the island
of Madeira. It grows on the sea-cliffs to the east of Funchal, about a mile from the town on the coast to	
Canico.

The species of the genus P. serrulata are evergreen trees with
undivided coriaceous serrated or entire leaves, and flowers in
terminal corymbose panicles, followed by small fruit. They require the same treatment as the species of Cratoxylum,
and are eminently ornamental.

P. serrulata has oblong acute serrated leaves, and is a
native of Japan and China. It has been long cultivated
in Great Britain as a standard in the open air, in warm
situations.

R. indica, in our warmest

1. Fit associates for it against a wall. Pho-
tinia arbutifolia, Cratoxylum glaucum, C. mexicana, Raphoelepsia
indica, and Eriobotrya japonica. Three other species, P. arborea, P. integrifolia, P. dubia,
have been cultivated in this country. There are four
or five other species described, natives of Asia, which might
probably be cultivated with success.

The species of Eriobotrya are less hardy than those of the
last genus. They are small trees with tomentose branches, broad simply serrated leaves, which are woolly beneath, with woolly compound terminal racemes of flowers, and subulate deciduous bracts. *E. japonica* is the common Loquat. It has broad elliptic serrated rather wrinkled leaves, tapering at the base and usually toothed at the apex. The flower is a small tree a height of from 10 to 20 feet, and is a native of China and Japan. The fruit is of a middling size, pear-shaped, yellow, downy, and disposed in large pendulous clusters. The leaves of the plant resemble the apple, and are said to be equally good with that of the mango. Lord Bagon has grown this tree at Blithfield, where it bears fruit, which is represented as having a flavour equal to that which is produced in Cyprus. It is at its best in the months of July, August, and September, and kept in a very warm house during the rest of the year. There are four other species of *Loquat*, but none have been introduced into cultivation in this country. Amelanchier is another genus separated by Lindley from the old genus *Amelanchier*. The species are small trees, natives of Europe and North America, with simple serrated deciduous leaves, white racemose flowers, and linear-lanceolate deciduous bracts. They are cultivated in British gardens on account of their early white showy flowers, their fruit which ripens in June, and the deep yellow red which their vegetation assumes in autumn. *A. vulgaris*, the common Amelanchier, has roundish-ovate bluish leaves, downy beneath, glabrous afterwards; the fruit is of a purplish colour, and is ripe in June. It is also found on rocky banks in many parts of the continent of Europe. It has been in cultivation in England since the year 1896. *A. betulina*, the Grape-Tree, has oblong-elliptical or ovate, acute, acuminate leaves, glabrous; the fruit is a dark yellow, and is ripe in August. It is also found in many parts of the continent of Europe. It has been in cultivation in England since the year 1896. The *Pyura elegans* of Sir J. E. Smith has been made into the genus *Osteomeles* by Lindley. At present this is the only known species. It is a shrub, native of the Sandwich Islands, with pinnate leaves and a small fruit crowned by the styles and calyx. The species of *Cydonia* yield the fruit called the Quince. *Cydonia vulgaris*, or Quince, P. C. C. Independently of this recommendation, they are very useful as stocks for other species, which are desirable for the ornamental plantation. *C. vulgaris* grows in the countries of the eastern world in the wild state, and is very common in cultivation. It has ovate leaves, oblong at the base, entire, tomentose beneath, and in a short time becomes glabrous. The flowers are small, white, and red, succeeded by a large globular or pear-shaped yellow fruit. It is at the present day apparently indigenous in the south of France, Germany, and the banks of the Danube, and it has been cultivated from time immemorial. The *Cydonia orientalis*, *Hort. Plant. lib. 2, cap. 3*, is the variety *Cydonia vulgaris* molliformis of modern botanists, whilst the *spppns* mentioned in the same place is the *C. c. pyriformis*. In cultivation the quince offers a moist but free soil well drained. The finest specimens in this country are found in orchards near ponds. The best mode of propagating it is by layers. It may also be grown from cuttings planted in the autumn. The quince is a variety of the first species. Two other species, *C. sinensis* and *C. Japonica*, the Chinese and Japanese Quince, are often cultivated in this country. They require the same general treatment as the foregoing. The *Cydonia* is a variety of the first species. There is one other species of *Cydonia*, *C. Simboli-thina*, a native of Nepal, where it is called *Simboli-thina* or *Blue*, but it has not been introduced into this country. (From *The Vegetable Kingdom*; London, Arberetum et Fruticetum Britannicum.)

PONTEDERA CEE, *a natural order of plants belonging to the chief of Etiologra*... It has a 6-parted tubular coloured perianth, more or less irregular, with a distinct calyx. The stamens arising from the calyx 6 or 8 opposite the lobes of the calyx, and the anthers turned inwards, opening lengthwise. The ovary is free, more or less completely, 3-celled, many-seeded; one style, the stigma simple. The capsule 3-celled, occasionally dehiscent at the mouth. The plant is paludal and often submerged. The leaves are ovate or oblong, digitate, or divided. The flowers are usually or solitary in spikes or umbels, spathaceous; frequently blue, sometimes yellow, red, or purple. The sepals and petals are distinguished by the divisions of their flowers being rolled inwards after flowering, to which may be added mealy albumen and an indefinite number of seeds. They are natives exclusively of North and South America, the East Indies and tropical Africa. Very little is known of their uses. Some of the species are employed by the native Indian practitioners in liver complaints and diseases of the stomach. Rubbed down in butter and drank, they are said to remove redness of the eyes; powdered and mixed with sugar, to relieve asthma; and when chewed, to remove tooth-ache; bruised with oil, some are administered in fever and some eaten as pot-herbs.

(Lindley, *Vegetable Kingdom*.)

PONTIUS, P. A. L., a celebrated engraver, was born at Antwerp in 1588, and died at Florence in 1658. He engraved the plate of the dead Christ in the *Iliad* of Homer, and the figures of the *Antiquities of the Jews* of Pliny. He was employed by other artists, such as Abraham Blooteling, in 1603. The date of his death appears not to be known: the *Slaugther of the Innocents*, after Rubens, one of his principal works, is dated 1653. Pontius was the name of very ancient and illustrious Roman families, and he is chiefly distinguished for his excellent prints after Rubens, which he executed under that great painter's inspection. He engraved also a celebrated set of portraits after Vandyck, including those of many of the most distinguished Flemish painters.

PONTORMO, JACOPO DA, or Jacopo Carucci, a distinguished Florentine painter, was born at Pontormo, in 1494, and died at Florence in 1557. He was the pupil of Leonardo da Vinci, and he studied under Alberti, Bindoni, Piero di Cosimo, and Andrea del Sarto. He painted for some time in a similar style to Andrea, and was that painter's rival; but he frequently changed his manner, and three distinct styles are ascribed to him, progressively inferior; the last imitated from the works of Albert Dürer. Towards the close of his life he spent eleven years in painting some frescoes of the Deluge and the Last Judgment in the church of San Lorenzo, in the manner of the imitators of Michael Angelo, but they have long since been whitewashed over.

(Vasari, *Vie de' Pitori*, &c.; Lani, *Storia Pittorica*, &c.)

POOR LAWS, SCOTLAND. The foundation of the Old Poor Law of Scotland was the act of parliament, 1579, c. 74, which in its principal respect resembled the celebrated English statute of the fourteenth of Elizabeth, passed a few years earlier, as to have been considered a mere adaptation from it. The Scottish act, however, fell short of the English in the one important particular of not providing for the care of the able-bodied. By this old act, a settlement was acquired by birth, and once established could not be changed unless by a seven years' industrial residence in another parish. By the act of 1675, c. 18, this period was shortened to three years. The method of administering the law, which arose partly out of the terms of the old acts, partly out of custom, and partly from directions given to the assessors of the poor, and, in the judgments of the courts, was as follows:—In the rural parishes, the 'kirk sessions,' or lowest ecclesiastical judicatures, consisting of the parish clergyman and certain elders, shared the management with the 'bishops,' or refusal of orders, but it became customary for the latter body to interest themselves solely in the voting and levyng of the rate, leaving its distribution and the management of the poor to the former. This plan became the basis on which the assessment and management lay with the corporate authorities. The funds for the relief of the poor were of two kinds, the collections at church doors, along with certain fees and exchequerary bequests, constituted the revenue assessed rates on the parish, or a substitute voluntarily paid instead of an assessment, the other. Of the sums collected at the church doors only a half went to the regular relief of...
POO

POUR

those legally entitled to relief; the other became a fund for general charitable purposes at the command of the kirk session. The former was, on paper, a fund, and the regular practice came to be, that if the miscellaneous sources were insufficient for the relief of the poor, the heritors and session in a country parish, or the magistrates in a town parish, might levy a rate on the property of the particular vestry or kirk session chiefly interested to agree to a 'voluntary assessment,' for the purpose of postponing the imposition of a fixed legal rate. When an assessment was imposed, it became a rule that onehalf of the money should be paid in land, in respect of their land; the other on householders, in respect of their 'means and substance,' or their incomes so far as not derived from land. The adjustment of the rating was the greatest difficulty and several different parishes followed very distinct methods in practice.

For a considerable period, the Scottish system was very favourably received by political economists, who saw the country in a comparatively sound moral condition, with a pari-munimous poor law, while the lavish system of England seemed to promote profligacy and idleness. But from the time when these systems were first promulgated to the completion of the great change of the English poor law, a vast internal alteration had taken place in the social economy of Scotland. The comparative low rate of wages, attracting manufacturing capital from England, had caused a more than average migration of the rural labourers to the manufacturing districts, and a peculiarly rapid increase of the city population. It was found that with these complicated materials, the almost uncontrolled facilities of the national system where each member watched over the interests and the conduct of his neighbour, was incapable of grappling. It was found that even for poor country districts the system was unsuitable, because the greater part of the funds of the system in production, the administrators were compelled by the voice of public opinion to become more liberal in their dispensations, while the managers of the country parishes not subject to the same influence, kept down their allowances, and thus gave the poor an inducement to endeavour to obtain a settlement by three years' industrial residence in the cities. Dr. Chalmers was the great champion of the old system. With the assistance of some enthusiastic followers, he organised the administration of a parish in the poorer parts of Glasgow, as a demonstration of the efficiency of which the system was capable. It was a very pleasing picture, but the public soon felt that the success with which one energetic individual and his enthusiastic followers might voluntarily perform the duties generally exacted by legal compulsion, was no sufficient ground for believing that the rest of the community can be at all times and in all places dependent upon the performance of onerous public services without the coercion of law.

The public were first awakened to the imperfections of the Scottish poor law by Dr. W. P. Alston, a physician in Edinburg and one of the presidents of the practical societies in that city. Having frequently administered professional services to the poorer classes, he showed from his own experience that the utter inadequacy of the provision afforded to those who worked, was the chief cause of the necessity of such aid. It was a common experience that the poor, who had done work, were reduced to want, and was an extensive cause of disease, vice, and misery. The city population speedily answered to this appeal, and associations were formed, and inquiries made in various directions. It was shown that the amount expended on the relief of the poor in Scotland amounted to little more than a sixth part of the sum 'distributed throughout an equal population in England and the U.S.A.' on the poor law.

In England, the expense of supporting the poor amounted to 6s. 10d. per head of the population; in Scotland, to 1s. 2d.

In some of the Highland parishes, whence the most destitute objects emigrated over the rest of the country, the allowances were ludicrously small; and a Report made to the General Assembly of the Church of Scotland in 1830, enumerated instances where sums averaging from 3s. to 1s. yearly were solemnly awarded to deal with people, as the poor law made for their wants. In the mean time, the discussion of these matters had a tendency gradually to increase the amount of the provision for the poor. The practice of distributing some considerable sums by the kirk session to parliament in 1843 shows that between 1826 and 1841 the sums raised by assessment had increased from 89,101l. to 228,824l.; while the sums raised by voluntary assessment had increased from 1,195l. to 1,296l. Of the institutions in Scotland they were appointed to inquire into the whole state of the subject, and after hearing much evidence, they presented a Report, accompanied by a voluminous appendix, in 1843. The amendments proposed in this Report were supposed to be of somewhat considerable importance, on account of the country expressed dissatisfaction with them; and in 1845 a measure was passed embodying alterations considerably more extensive.

By this act, 8 & 9 Vict. c. 63, a board of supervision is appointed to replace the old local board, the members connected with municipal bodies and the administration of justice in Scotland, with one salaried member, who gives constant personal attendance. The office of the board is in Edinburgh. This board is endowed with all the powers of the local boards and is not, and the system of relief is administered. The board has, however, no directory or prohibitory control over the proceedings of the local boards. In some of these bodies, some of the provisions of the act. In the rural parishes where there is an assessment, the local board is to consist of landowners to the extent of 20£. annual value, the kirk session, and certain elected representatives of the other rate-payers, according to the number fixed by the board of supervision. In city parishes, the boards are each to consist of four persons named by the magistrates, not exceeding four from each kirk session in the city, and certain elected persons according to a number and qualification fixed by the board of supervision. In parishes where there is no assessment the management is to continue under the old laws. The board may provide machinery for levying or exacting a rate for the poor, unless in those parishes where the persons more immediately concerned agree to such a measure. It is held, however, that the board of supervision has no power of interfering with the funds from the respective parochial authorities the relief which they are entitled to put necessary to pay the collectors of the funds to the disposal of the distributors of relief, and this can only be as a result of the act. It is important to note that persons apply for relief, it is provided that, though they have no settlement, if the claim would be in the case of their having one in the parish where it is made, it is necessary that they be assessed. They are thus enabled to add to the funds. When relief is refused, the applicant may apply to the sheriff, who may grant an order for temporary relief, and then hear parties, and decide whether the applicant is or is not entitled to relief. In this form, however, neither the sheriff nor any other judge can decide on the adequacy of relief. The initial step to any judicial appeal against the amount of the relief afforded is, by an application to the board of supervision, and on that body reporting its concurrence, the applicant is placed on the poor-roll of the court of session, where he has the privilege of the question being discussed gratis. By this act, provision is made for medical attendance and medicines, being part of the system of pauper relief, and for the education of pauper children. It is provided, that for the purposes of the act, parishes may be united into 'combinations.' By a special clause, nothing in the act is to be construed as excluding any that may be established by the state of doubt in which it stood before the passing of the act. Men deserting their wives and children are made liable to punishment as vagrants, a provision which it is hoped may curtail the number of those who resort to a laudable and the law of Scotland—the absence of any means by which deserted wives can make effectual claims on their husbands for sustenance to themselves and their children, without a regular action in the court of session. By the new act, a new and more specific mode of ascertaining the amount of the assessment between landed and other property has been attempted to be established, and this provision is already full of distressing discretion of property, and for the time necessary to acquire an industrial settlement is increased from three to five years.

POPLARS, POPLUS. [Salicaceae, P. C.]

PORCELLIUM, a fossil genus of Heteropodinae. Mollusca allied to Bellerophon. From the mountain limestone. (Leviellis.)

PORES OF PLANTS. [Stomata, P. C.]

POROSITY is the condition of natural bodies which consist in the discontinuity of their molecules, the intervals between these being pores (from δορα, a passage). Porosity is a property common to all the bodies of nature, at least within the cavity of any one of them, and a body is said to one another. In some, as sponge and coral, the pores are visible to the eye, and in others they may be rendered so by the aid of a microscope. In bodies whose pores are not thus enlarged, the porosity is proved by various circumstances. Thus water or mercury being contained in an open vessel of wood over the exhausted
receiver of an air-pump will, by the pressure of the atmosphere, be forced through the wood and fall from thence in a shower; liquids also are frequently filtered by being made to pass through the pores of paper; and in the florentine experiment, for determining whether or not water is compounded with the waters of rivers and seas. In the latter case the power of the vessel of gold in which it was contained. Again, the porosity of bodies is inferred from their elasticity and the sounds which are heard when the molecules are in a state of vibration: the sounds in air are not in part negligible but it is generally observed that the bodies prove it from the fact that the particles of light pass through them, or that the vibrations of an animal fluid take place without doing any harm. The second and third cases this demand even to sketch out his designs, done by young Ker Porter, hardly then in his twentieth year. This picture was burnt in the fire which consumed a friend's warehouse where the painter deposited it before he left England to go to Russia; but the sketches exist, and were sold at the sale of Sir Robert's effects in 1843. Another great battle was the Siege of Acre, exhibited also in the Lyceum Room in 1801: he published at the same time a book entitled 'The Siege of Acre, chiefly intended as a companion to the great historical picture painted by Robert Ker Porter, now exhibiting at the Lyceum, 1801;' it contains spirited etchings of the picture. These were followed by a series of other works, in which he painted the Battle of Alexander the Great, which he presented to the City of London, and it is still in the possession of the corporation: it was hung up in the Guildhall a few years ago. He also painted pictures of the Battle of Salamis, and the Battle of Actium, which was arranged; but some ministerial differences caused him to leave Russia; in the year 1811, however, the marriage took place, and the princess survived him. He painted at St. Petersburg, on one of the plans of the city, the Battle of St. Petersburg, in 1813, and in 1815 painted the Battle of Borodino, in which he occupied his extensive travels in Asia, of which he published a detailed account in 1821-22:—"Travels in Georgia, Persia, Armenia, Ancient Babylonia, &c., during the years 1817-18-19-20." The Costume of Greece, Persian Costumes, Antiquities, &c., 2 vols. 4to. In this work are many excellent designs in outline from the fine characteristic ancient sculptures of Naxos, Samos, Rhodos, &c. Some of the figures of these sculptures, which in Le Brun's time (1704) were mere headless trunks, are represented by Niebuhr ('Reisebeschreibung,' &c., ii. 180), half a century afterwards, with eyes and noses complete, but executed with out the least skill whatever; the representations of Sir John Chardin are not much better.

In 1832 Sir Robert Ker Porter was created Knight Commander of the Order of St. John of Jerusalem. He died at Paris on the 13th of May, aged 67, and was interred at Nice on the 15th. He was appointed a few years before British consul at Venezuela, where he resided at Caracas until 1841, and he painted while there three sacred pictures, which were his last principal works; he also attempted several separate works, and was induced by his evidence of talent to take him to London, in order that he might have the opportunity of instruction in the Royal Academy. His mother took him, in about 1790, to Westminster, where he procured the present picture, but hard by was so much struck with the spirit of the boy's sketches, that he procured his admission into the academy, and predicted his certain success with confidence. Sir Robert's confidence in his own sound judgment was so much the same as any other. In 1793 he had already evinced such extraordinary progress as to receive a commission to paint an altar piece for Shoreditch church. In 1794 he presented an altar-piece of Christ alloying the Storm to the Roman Catholic chapel at Portsea; and in 1798 another of St. John preaching in the Wilderness, to St. John's College, Cambridge. His most extraordinary productions, however, were his great battle-pieces, displayed in the main hall of the college. Between the years 1795 and 1800 he painted the storming of Seringapatam. He is said to have been only six weeks in painting the picture, and yet the execution was so true to life, that the portraits of the principal actors painted by a number of the academicians then occupied in preparing the exhibition, and said, 'he had just looked on what he must consider a wonder in the art: a work of such dimensions, finished through and from that period he was called upon by the demand even to sketch out his designs, done by young Ker Porter, hardly then in his twentieth year. This picture was burnt in the fire which consumed a friend's warehouse where the painter deposited it before he left England to go to Russia; but the sketches exist, and were sold at the sale of Sir Robert's effects in 1843. Another great battle was the Siege of Acre, exhibited also in the Lyceum Room in 1801: he published at the same time a book entitled 'The Siege of Acre, chiefly intended as a companion to the great historical picture painted by Robert Ker Porter, now exhibiting at the Lyceum, 1801;' it contains spirited etchings of the picture. These were followed by a series of other works, in which he painted the Battle of Alexander the Great, which he presented to the City of London, and it is still in the possession of the corporation: it was hung up in the Guildhall a few years ago. He also painted pictures of the Battle of Salamis, and the Battle of Actium, which was arranged; but some ministerial differences caused him to leave Russia; in the year 1811, however, the marriage took place, and the princess survived him. He painted at St. Petersburg, on one of the plans of the city, the Battle of St. Petersburg, in 1813, and in 1815 painted the Battle of Borodino, in which he occupied his extensive travels in Asia, of which he published a detailed account in 1821-22:—"Travels in Georgia, Persia, Armenia, Ancient Babylonia, &c., during the years 1817-18-19-20." The Costume of Greece, Persian Costumes, Antiquities, &c., 2 vols. 4to. In this work are many excellent designs in outline from the fine characteristic ancient sculptures of Naxos, Samos, Rhodos, &c. Some of the figures of these sculptures, which in Le Brun's time (1704) were mere headless trunks, are represented by Niebuhr ('Reisebeschreibung,' &c., ii. 180), half a century afterwards, with eyes and noses complete, but executed with out the least skill whatever; the representations of Sir John Chardin are not much better.

In 1832 Sir Robert Ker Porter was created Knight Commander of the Order of St. John of Jerusalem. He died at Paris on the 13th of May, aged 67, and was interred at Nice on the 15th. He was appointed a few years before British consul at Venezuela, where he resided at Caracas until 1841, and he painted while there three sacred pictures, which were his last principal works; he also attempted several separate works, and was induced by his evidence of talent to take him to London, in order that he might have the opportunity of instruction in the Royal Academy. His mother took him, in about 1790, to Westminster, where he procured the present picture, but hard by was so much struck with the spirit of the boy's sketches, that he procured his admission into the academy, and predicted his certain success with confidence. Sir Robert's confidence in his own sound judgment was so much the same as any other. In 1793 he had already evinced such extraordinary progress as to receive a commission to paint an altar piece for Shoreditch church. In 1794 he presented an altar-piece of Christ alloying the Storm to the Roman Catholic chapel at Portsea; and in 1798 another of St. John preaching in the Wilderness, to St. John's College, Cambridge. His most extraordinary productions, however, were his great battle-pieces, displayed in the main hall of the college. Between the years 1795 and 1800 he painted the storming of Seringapatam. He is said to have been only six weeks in painting the picture, and yet the execution was so true to life, that the portraits of the principal actors painted by a number of the academicians then occupied in preparing the exhibition, and said, 'he had just looked on what he must consider a wonder in the art: a work of such dimensions, finished through and from that period he was called upon by the demand even to sketch out his designs, done by young Ker Porter, hardly then in his twentieth year. This picture was burnt in the fire which consumed a friend's warehouse where the painter deposited it before he left England to go to Russia; but the sketches exist, and were sold at the sale of Sir Robert's effects in 1843. Another great battle was the Siege of Acre, exhibited also in the Lyceum Room in 1801: he published at the same time a book entitled 'The Siege of Acre, chiefly intended as a companion to the great historical picture painted by Robert Ker Porter, now exhibiting at the Lyceum, 1801;' it contains spirited etchings of the picture. These were followed by a series of other works, in which he painted the Battle of Alexander the Great, which he presented to the City of London, and it is still in the possession of the corporation: it was hung up in the Guildhall a few years ago. He also painted pictures of the Battle of Salamis, and the Battle of Actium, which was arranged; but some ministerial differences caused him to leave Russia; in the year 1811, however, the marriage took place, and the princess survived him. He painted at St. Petersburg, on one of the plans of the city, the Battle of St. Petersburg, in 1813, and in 1815 painted the Battle of Borodino, in which he occupied his extensive travels in Asia, of which he published a detailed account in 1821-22:—"Travels in Georgia, Persia, Armenia, Ancient Babylonia, &c., during the years 1817-18-19-20." The Costume of Greece, Persian Costumes, Antiquities, &c., 2 vols. 4to. In this work are many excellent designs in outline from the fine characteristic ancient sculptures of Naxos, Samos, Rhodos, &c. Some of the figures of these sculptures, which in Le Brun's time (1704) were mere headless trunks, are represented by Niebuhr ('Reisebeschreibung,' &c., ii. 180), half a century afterwards, with eyes and noses complete, but executed with out the least skill whatever; the representations of Sir John Chardin are not much better.
made: for his constitution, then insued to the warm climate of Venesuela. Sir Robert himself, in a letter dated only the 6th of May, announced his intention to his brother, Dr. Porter, of Bristol, of embarking immediately for England; on the following day, however, a letter was written by the chaplain of the British embassy announcing his death by apoplexy. The body was put in an extract of opium, but, Sir Walter] and the night of the 23rd, Sir Robert went to court to pay his respects to the emperor, and afterwards made two or three visits to private friends: on arriving at his house about three o’clock in the afternoon, Sir Robert, in opening the glass of the carriage, perceived that his master was holding himself in, and that he moved to the door with much difficulty; but before he could descend the steps he fell down from the effects of an apoplectic fit, and the carriage was hurried up town. The water, soon after which consciousness ceased, and he expired at eight o’clock this morning (May 4, 1842), in his sixty-second year. His effects were publicly sold in London, in March, 1843.

(Athenaeum, 1842-43, and the Artist’s Works.)

PORTFIRE is a composition consisting of saltpetre, sulphur, and mealed gunpowder, mixed together by being rubbed between the hands, and, after being passed through hair-sieves, moistened with spirits of wine: the mixture is then rammed or driven into a paper case of a cylindrical or conical form, and less than an inch in diameter. A piece of portfire sixteen-teen or twenty times as large as this had been kept up in the same manner for about fifteen months.

It is sometimes used as a match for firing artillery, in which case the saltpetre, sulphur, and powder are in the proportion of 6, 2, and 1, respectively. This powder is frequently employed in breakout, or in blasting rocks, when the proportions of the like ingredients are as 7, 2, and 8, respectively. For these last purposes the portfire is attached at the extremity of a long stick, and passed in the shaft bored in the rock or object to be blasted; and the fire is applied to it by a match.

POSITONOMYA. [POSITONIA, P. C.]

POSSIBILIO FACTRIS. [DESCRIPT, P. C.]

POST HOBSES. [POSTING, P. C.]

POTAMOGETON (from ὑγρός, a river, and the termination τέρπειν, which probably means ‘produced’), a genus of plants belonging to the Endogenae class, and the natural order Potamone. It has a perfect flower, a 4-parted perianth, 4 sessile anthers opposite to the divisions of the perianth, 4 ovaries, and 4 drupes or nuts. The species are water-plants.

P. natans is a British plant, with floating oval stalked leaves, the petals plano-concave above, the nuts large, rounded on the back when fresh keeled; when dry the peduncles are equal. There is a creeping rhizoma at the bottom of the water. The roots are sometimes eaten in the wilds of Siberia by men, but in more temperate regions are fed on only by swans, who devour them with avidity.

P. crispus has a compressed stem, pellucid oblong linear leaves, sessile and wavy, the nuts with long beaks, keeled on the back. The seeds are dry the peduncles are equal. It is a native of Great Britain. P. densiss has its leaves all opposite, pellucid, clasping, elliptical-lanceolate or lanceolate; the spikes shortly subulate, ultimately contracted into a spike-like fruit. It is found on ditches and ponds of water in England. Ducks feed on the seeds and leaves of both these species, but they serve a more important purpose in giving out oxygen, and rendering the water respirable for fish and other aquatic animals. There are twenty British species of Potamogeton, and Haller says in the Swiss lakes P. serruriu grows to the length of from 10 to 20 feet, forming extensive subaquatic forests.

(Barnet’s Outline of Botany; Babington’s Manual of British Botany.)

POTAIOUMYA, a genus of Conchiola from the freshwater streams of the Potomac Mountain, of the Lake of Wight. (Sowerby.)

POTENTILLA (potent, powerful, from the supposed medical qualities of some of the species), a genus of plants belonging to the natural order Rosaccemae. It has a concave calyx from 4 to 5-parted, with 4 or 5 bretels; there are from 4 to 10 petals, with inconspicuous stamens, a lateral ovary, and a nearly terminal style. The fruit consists of numerous small nuts placed on a flatish dry receptacle; the seeds pendulous or ascending, the radicle of the flowers white, and the flowers yellow. P. rotundifolia, Cuminginn, is a common British species: it is found likewise in other parts of Europe. The style is filiform, procumbent, and creeping; the leaves quinate and stellate-pinnatifid; the flowers white, and the peduncles solitary or corymbose, the flowers yellow, small, with the parts of the calyx and corolla in fours on slender hairy stalks much longer than the leaves. It is the Potentilla erecta of Linnaeus. It abounds in Great Britain, and is used as a medical remedy, and has been medicinally. In the Western Isles of Scotland and the Orkneys they are used for tanning leather, and are preferred even to oak-bark. They are also used for dyeing a red colour. As a medicine they are much used; and are also thought to be serviceable in some diseases to which sheep are subject.

F. amercia is a creeping stem, interruptedly pinnate leaves; the leaflets numerous, oblong-cordate serrate, silky beneath; the peduncles solitary. The flowers are large and yellow, and the leaves form a favourite food with geese: they are sometimes used as pot-herb. Its roots are eaten both by hogs and men; they taste like a pea-soup, but are small; the common people roast or boil them for food. In the islands of Tiray and Col they answer in some measure the purposes of bread, and have been known to support the inhabitants for months at a time during times of scarcity.

The leaves of P. fruticos and P. reptis are employed in Siberia as a substitute for tea.

P. hispidus (from hispis, a few-flowered stem; the leaves with 5 or 7 leaflets, pilose, and cut at the apex; the stigmas lanceolate, entire; the petals obcordate, longer than the calyx. It is native of the Pyrenees, South of France, Sicilia, &c., and is the Bardana of Hippocrates, &c., &o., &c., &.

All the species of Potentilla are of easy cultivation, and some of them are handsome when in flower. They will grow in any common garden-soil and are easily propagated by dividing at the roots or by seed. The shrubbery kinds are very proper for the front of shrubberies, and they grow freely from cuttings planted in the autumn in a sheltered situation.

(Don, Gardiner’s Dictionary; Lindley, Vegetable Kingdom; Lindley, Flora Medica; Babington’s Manual of British Botany; Burnett, Outlines of Botany; Frass, Synopsis Flora Classicorum.)

POTERIUM (from poter, a drinking-vessel or cup, one of the species being infused in drink), a genus of plants belonging to the natural order Rosaccemae. It has monoeocious or polygamous flowers: a 4-leafed calyx, with three external scales at its base; and a quadrangular tube. The petals are wanting, the style terminal, stamens numerous, and the seed suspended.

P. sanguis-ost, lesser Burnet, is an herbaceous plant, with a slightly angular stem, the calyx of the fruit quadrangular and hairy, the nut has the leaves pinnatifid, the ovaries ovate corymbose serrate leaflets, glabrous or slightly hairy beneath. It is found on dry calcareous soils in Great Britain. It forms a useful fodder for cattle, and at one time was extensively cultivated. It is now generally superseded by safflower and other artificial grasses. On the Continent, and occasionally in this country, the young leaves are eaten as salad, and it is said to form one of the ingredients of the favourite cool tankard. It is said to give the name to the species, from the custom of infiltrating it in liquors. The common people of Siberia eat the roots. There are about nine species of Burnet described, which are distributed over Europe, Africa, and America. The hardy herbaceous species will grow in any common garden soil, and are best propagated by seeds, as most of them are little better than biennial plants. The shrubbery species thrive best in a light rich soil, and young cuttings may take a good position as a hedge, or may be laid on the ground on which it is to grow upon themselves or round the vessel in which they are confined; they are likewise exposed to great varieties of temperature and defeat, and can suffer much without moisture. It is therefore the object of the careful gardener to have as large a collection of these plants as is possible; and at the same time to secure the advan-
gages derived from the operation itself. These advantages consist mainly in the facility with which it enables the gardener to change the arrangement and position of his plants; it also, by cramping the roots, diminishes the tendency to form leaves, and eases the disposition to flower. It secures a constant and effective drainage from the roots, and renders it more easy to expose them to a favourable amount of bottom heat. For the raising and nourishment of young seedlings it is also an advantageous process. Exchange of the soil is one of the inconveniences which result from this system. In order to remedy it liquid manure should be applied; or the plants placed in peat-soil, shallot earth, or vessels containing moss or other substances through which the roots can seep through holes in the bottom of the pot. It is however to shifting more particularly that recourse should be had for renovating the soil; and this, if skillfully performed without injuring the plant, is most successful. It is not alone for the purpose of improving the soil that shifting is desirable; the roots if allowed to remain long in a confined space form a hard knotted mass, which is very unfavourable to the retention of moisture and the growth of the plant. All the earth therefore which clings to the roots should be carefully separated before the plant is placed in the fresh soil. The roots of a plant are always found to be in contact with the sides of the pot, and this, being generally composed of a highly absorbent substance, is subject to great variations of temperature. The practice of plunging greenhouse plants into the earth during the summer to obviate this is very unsatisfactory, as when they are again taken up the roots are generally found to have taken advantage of the earth around them and to have fastened themselves in it. The best mode of countering the injurious effects of unequal temperature is, as the use of double pots, as recommended in the Gardener’s Mag. ix. 576, the space between the two pots being filled with moss or some other substance retentive of moisture. The drainage of potted plants is of great importance, and in all cases a quantity of broken pieces of tiles and earthware should be placed at the bottom of the pots to prevent the stagnation of water about the roots. To be managed perfectly a young plant should be placed in as small a pot as it will grow in, and gradually and successively transferred to large pots as it advances. Dr. Lindley says: ‘It is by paying constant attention to the shifting of the growing plant, by the employment of a very rich stimulating soil, and by thorough knowledge of the kind of atmosphere which suits them best, that have been obtained those magnificent pelargoniums, cockscobs, and balms, &c. that have so often and so justly excited the admiration of even the most experienced gardeners.’

(Lindley, Theory of Horticulture.)

POUNDAGE. (Subsidy, P. C.)

POW. We find that the article ‘Root, P. C.,’ does not answer the reference made from Powr, P. C. We briefly supply the defect here, and take the opportunity of describing some important suggestions which have been recently made as to the manner of conducting algebraical operations.

In P. C. leaves and roots are used in which the term power was introduced into arithmetical is seen. By definition, the fourth power of x means the product of four x's, or \( x \times x \times x \times x \), and the same of other powers. But it is far more symmetrical to begin from unity; and to say that the fourth power of x is the result of four multiplications by x, unity being understood as the commencement. Thus the successive powers of x, first, second, third, &c. are \( 1 \times x \), \( 1 \times x \times x \times x \), &c. denoted by \( x^1 \), \( x^2 \), &c. And the term root is the inverse of power, as follows: If A be the nth power of B, B is the nth root of A, denoted by \( \sqrt[n]{A} \).

The algebraical character of the roots is explained in Root, P. C.

It is thus easily proved that when m and n are any two integers,

\[ x^m \times x^n = x^{m+n} \]

when m is greater than n, \( x^m \times x^n = x^n \cdot x^{m-n} \), that is, \( x^m = x^{m-n} \), and that \( x^n = x^n \) whenever m is divisible by n without remainder. These rules, if applied in defiance of the restrictions first mentioned, lead to such results

\[ x^0 = 1, \quad x^1 = x, \quad x^{-1} = \frac{1}{x}, \quad \text{&c.} \]

which are unintelligible as far as the definitions have yet been stated. Their proper interpretations [interpretation, P. C.] are as follows:—First, \( x^m \) must be allowed to stand for unity, whatever \( x \) may be; secondly, \( x^{-m} \) must be understood to be \( \frac{1}{x^m} \); thirdly, \( x^n \) and \( x^n \) being positive integers, must stand for \( x^n \). When these new definitions are added, all the rules remain true, whether \( x \) and \( x \) be positive or negative, integral or fractional: and the system of algebraic powers is complete.

An algebraic expression is said to be arranged in powers of a letter, say \( x \), when the powers of that letter which enter are made to enter in ascending or descending order of algebraic magnitude. Thus \( ax^2+bx+c \) is not at present arranged at all. To arrange it in ascending or descending powers of \( x \), we must write it thus:

\[ \pm ax^2+bx+c = \pm a x^2 \pm bx \pm c \]

But even yet it is incomplete for many algebraical purposes, having no written indication of the fact that the ascent or descent is interrupted. Completely written in ascending powers, it should be

\[ ax^2+bx+c = a x^2 + b x + c \]

Written in this form, which may remind us of the use of a cipher in writing ordinary numbers, it is clear that we hardly read the expression as readily, and write it much more briefly if we omit \( x \) and its powers altogether, and make some distinctive mark, analogous to the decimal point, between the parts which belong to the positive and negative powers. Thus the above might be written:

\[ b^0+1a=1+0+0 \cdot a+1=1+0 \cdot a \]

the mark | being on that side of the adjacent + or — which belongs to the positive powers. This mark however is not necessary in what follows.

The late Mr. Horner [isvolteric, &c. P. C. and P. C. S.] was the first who suggested the systematic rejection of the ascending or descending powers. An example of multiplication and division will sufficiently explain it. Suppose it required to multiply \( 7x^2-2x-3 \) and \( 2x^2+2x-5 \):

\[ 7x^2-2x-3 \times 2x^2+2x-5 = \]

\[ 14x^4-14x^3-7x^2-14x+15 \]

Accordingly the answer is \( 14x^4-14x^3+7x^2-36x^2+27x+15 \), and every stroke of the pen which the usual method contains, more than is in the preceding, is mere waste, and risk of error into the bargain. Now let it be proposed to divide \( 4x^2-3ax^2+2x^2 \cdot ax^2-a^2 \) by \( 2ax^2-2x^2-a^2-a^2 \):

\[ 4-3+2 \cdot 0+0-11+12+2 \cdot 0+1 \]

Accordingly the quotient is \( 4x^2-12ax-24ax^2-44x \) and the remainder is \( 7x^2+36ax+64x^2 \).

Mr. Horner himself did not live to publish this suggestion, which, simple as it is, seems never to have been made before him. The possessor of his papers, Mr. T. S. Davies of Woolwich, published some extracts from those papers in an appendix to a reprint of the paper on the solution of equations, which reprint appeared in the ‘Ladies’ Diary’ for 1838; having previously introduced the simplification into the 11th edition of Hutton’s Course. Since that time a paper on ‘Algebraical Transformation in Equations’ by Mr. Horner to the Royal Society, but not printed in the ‘Philosophical Transactions,’ has been pub-
Hence the quotient is

\[
11 + 2m + 2n + 36n = 1 + 2m + 2n + 36n
\]

and the remainder is

\[
20m + 24m^3 + 48m^4 + 864m = 16x + 82x^3 + 64x^4 + 128x^5
\]

One of the easiest modifications of this rule is the division of \( ax^n + bx^{n-1} + \ldots \) by \( x - p \) or \( x + p \), as explained in fractions, decomposition of, P. C. S.

POZ. POZO DI BORGO (sometimes BARG) CARLO ANDREA, the half-disgraced diplomatist, was one of that considerable number of remarkable men produced by the island of Corsica in the earlier part and middle of the last century. He had ranked among the nobility of the island ever since the twelfth century; and he was born on the 8th of March, 1764, at Ajaccio, also the native place of Napoleon Bonaparte. The latter was the younger by five years, but they were in early life intimate friends. After having received a careful elementary education in his own country, Pozzo di Borgo went to finish his studies at Pisa; whence he had not long returned when Corsica, now under the dominion of France, was excited and shaken, like all the rest of that kingdom, by the outbreak of the Revolution of 1789. He had attached himself to General Paoli; and, under the patronage of that venerable head of the patriots, he was appointed, along with General Cabasson, to proceed to Paris in 1791 at the thanks of Corsica to the Constituent Assembly for having declared the island an integral portion of the French territory. This mission led to his being nominated a member of the Legislative Assembly, which commenced its session in October, 1791. While occupying this position he is stated to have attracted considerable notice by the knowledge and talent he showed in the diplomatic committee. When the Legislative Assembly was dissolved, in September, 1792, he returned to Corsica, and there joined Paoli in those efforts by which he accomplished the liberation of his country for a season from France, and the restoration of a native government under the protection of the convention. The constitution was established, in the summer of 1794, Pozzo, who had previously acted as one of the Secretaries of the General Consult held at Corte, by which the constitution was drawn up, was appointed, according to his biographer M. Capédiègue, President of the Council of State, that is, we suppose, the Board of Council, nominated by the King of England to assist the Viceregal. When the English abandoned Corsica, in 1797, he came to this country with the Viceregal infant, (afterwards Earl of Minto); and he remained here for about a year and a half. While in England Pozzo was considered as the principal adviser and agent of the French refugees; and it is from this period of his life that we derive the real name of his original, not the formal, commencement of his diplomatic career. In 1799 he proceeded to Vienna, where he attempted unsuccessfully to bring about a coalition between Austria and Russia.

He continued his residence at Vienna during the subsequent years, and after the conclusion of the treaty of Amiens, in 1802, he entered the diplomatic service of Russia, in which he spent the remainder of his life. Having been made a Councillor of State, he was first sent on a mission to Vienna, whence, after a few months, he was despatched in the character of Russian commissioner to the army, composed of English, Russian, and Neapolitan forces, in the North of Italy. After the battle of Austerlitz and the peace of Freiburg (December, 1805) he returned to Vienna, and thence proceeded to Petersburg. When Prussia rose against Napoleon in October of the year following, and was about to be joined by Russia, Pozzo received the military rank of colonel, and was to have accompanied the emperor as one of his suite, when the scheme of the confederates was struck to the ground and annihilated by the fatal battle of Jena (14th October, 1806). He now proceeded once more to Vienna, where he endeavoured, without success, to induce Austria again to take up arms. Meanwhile war had, at the instigation of France, been declared against Russia by the Porte (30th December, 1806). In the beginning of the year 1807 he joined the English fleet which was sent, under Sir Thomas Duckworth, to force the passage of the Dardanelles. He was present in the battle fought between the Russian and Turkish fleets near the island of Tenedos on the 1st of July, when the Turks were signalily defeated. But on the 7th of the same month Russia made peace with France by the treaty of Tilsit, one of the articles of which provided for an armistice between...
Russia and the Porte, which was accordingly concluded on the 24th of August following. Pozzo, all whose feelings were vehemently anti-Galicen, now obtained Alexander's permission to travel; upon which he proceeded to Vienna, and he received, with joy, the tidings of the total destruction of the fifth Anglo-Austrian coalition against France by the peace of Vienna (14th October, 1809).

He now betook himself to Constantinople, whence he proceeded to Persia, where he was appointed, by the Sultan, as his envoy, in the end of 1810. There he remained till after the expulsion of the French by the Romans in the winter of 1812; when he was recalled by Alexander; and, passing through Sweden, he met the emperor and the queen, who were, by the treaty of 1810, prince royal of Sweden, had already engaged to join the combination against France by the treaty of Peters burg (24th March, 1812); but he still hesitated to commit himself by any actual movement. Pozzo, who had had an interview with him on his way to Kalisz, was now sent to urge him upon the same terms that other negotiations were opened with Moreau, and with Murat and Eugene Beauharnais; and he at last succeeded in overcoming his scruples. After the Congress of Prague (July, 1813), Pozzo, now raised to the rank of major-general, was sent to Bernadotte at Berlin; and it is said to have been by his representations that the Swedish prince-regent was prevailed upon to take part in the battle of Leipzig (18th October, 1813). Meanwhile, immediately after the previous affair of Grosberin (23rd August), Pozzo had been despatched to Frankfort, to take part in the military council, where it was determined that the destruction of the enemy, which was in the beginning of January, 1814, he proceeded to London, charged with a request from the allied sovereigns that Lord Castlereagh might be sent over to join their deliberations. He soon returned from that mission, and was appointed minister, with whom he proceeded to Bautzen, where the allied sovereigns were now assembled. He continued in close attendance upon the Emperor Alexander at the Congress of Chaussé, where he strenuously opposed the proposal of the French to offer the offers made by Bourbon, and throughout the rest of the campaign of the first months of 1814, till they had the satisfaction of seeing Paris together on the memorable 1st of March. Pozzo, after the death of the Emperor, was placed in command of the forces, guarding the passage of the Niemen, keeping Alexander steady and in determining him to give up the restoration of the Bourbons, was now nominated Russian commissioner to the provisional government, and was soon after despatched to England to bring over Louis XVIII., with whom he returned to Paris on the 3rd of May. He remained in the French capital till the meeting of the Congress of Vienna in the beginning of November. At the conferences there he advised that the deposed emperor should be sent out of Europe; and he is said to have produced some coldness towards him for a time on the part of Alexander by his violent opposition to the project of the liberation of the Czar of restoring the old kingdom of Poland. The changed aspect of things, however, that followed the escape of Bonaparte from Elba (1st March, 1815) at once chilled Alexander's mind, and inspired him with the notion of the restoration of Napoleon. The latter immediately proceeded to Louis XVIII. at Ghent, and, having then joined the allied army as Russian commissioner, he was present in that character at the battle of Waterloo, where he received a wound. He now returned to Paris, and, declining Talleyrand's invitation to take office in the French ministry, resumed his former functions of Russian ambassador, and in that capacity he signed the Treaty of Paris of the 20th November. Soon after the Duke de Richelieu, now head of the ministry, conferred upon him the rank of a count and peer of France. He does not appear to have again left Paris till he was sent, after the Spanish campaign of the Duke of Angouleme, to report on that event, from which, however, he soon returned to the French capital. The death of the Emperor Alexander and the accession of Nicholas (31st March, 1825) did not alter his position; and he retained it, till the year 1828, after which he was recalled to St. Petersburg in 1824. Passing on his journey thither through Vienna and Berlin, he had the Order of the Red Eagle conferred upon him by the decrees of Alexander, which were passed by order of the emperor, by which the breaking out of the War of the East in 1825 he was sent on a mission to London; after a stay of only a few months he returned to his former post at Paris; but he was soon sent back to Petersburg from the land to which he had been sent, to the Great Britain. According to M. Capefigue, he felt this appointment as both a mortification and a disgrace, and it affected him greatly: but M. de Nessebois consoled him with the promise that as soon as they should have turned the Duke of Wellington from his inclination to join with Austria (de se rapporcher de l'Autriche) in the Eastern question, and should have supported the Tories in an effective manner, then they would give the task to Pozzo. Pozzo should to follow the French customs and pursuits. M. Capefigue, as is well known, deals largely in all his writings in information of this sort, of which no other writer has had the luck to hear, and which we must admit to be among the most instructive. Count Pozzo, however, got back to Paris ere long; and all that there is further to be told of him is that he died in that capital on the 15th of February, 1842.

(Absented, with the rest of the deets, most of which we have supplied, from a very elaborate article in the Biographie Universelle, vol. 77 (Supplement), pp. 497-507, by M. Capefigue, which has also been published separately.)

PRELATE (Busaco, P. C.)

PRESCRIPTION, by the law of Scotland, a much wider operation than either by the civil law or the law of England, supplying the place of the Statute of Limitations in the latter system. It not only protects individuals from adverse proceedings which other parties might have conducted if the lapse of time has not taken place, but it in some instances creates a positive title to property. The prescription or title by the act of the years 1796 and 1797 is no longer said generally to preclude the right of exacting performance of any claim, as to which no judicial attempt has been made to exact performance for fours years from the time when it was supposed to be due. The right to a thing of value must be both positive and negative. The party holding the property must, by himself or those through whom he holds, have been forty years in unchallenged possession of the property on a just and reasonable ground—in this is called positive prescription; and the claimant and those whom he represents must have been forty years without an ostensible title, and must, by not judicially attacking it, have tacitly acquiesced in the possession. An action raised in a competent court interrupts the long prescription. It is usually stated in the Scottish law-books that it is interrupted by the mortality of any person who could challenge the opposing right; but it would be more correct to apply in this case the phraseology of the French lawyers, who say it suspends prescription, as the years of minority are merely not counted in making up the period of the prescriptive right when there is a judicial interruption, a new period of forty years commences to run. When the prescription applies to a pecuniary obligation, payment of interest or an acknowledgment of the obligation, it is said to be interrupted, not by the death of the obligor, that, by a sort of analogy from the system of prescription, when there is in Scotland any judicial inquiry as to the antiquity of a custom, it is usual to limit the period of the prescriptive right to forty years, as in England. Such a period as has existed from time immemorial. It has been having the practice in the neighbourhood of Edinburgh for the proprietors of land to irrigate fields with the contents of the city sewers—the system increasing until it became offensive to the neighbourhood—these proprietors produced evidence of having their continued the practice for forty years; and although it had during that time increased from an evil felt only by the individuals immediately concerned with the practice, to the extent of a public nuisance, these proprietors have, so far as the dispute has hitherto gone, been able to defend themselves on the ground of prescription.

The other and other prescriptive systems cut off particular descriptions of claims or methods of supporting them. By the vicennial or twenty years' prescription, holograph writings, not attested with the usual solemnities of Scottish writers, cease to have any character of 'bear' and are presumed, after the passage of the Revolution of 1800; but he at last revisited St. Petersburg in 1824. Passing on his journey thither through Vienna and Berlin, he had the Order of the Red Eagle conferred upon him by the decrees of Alexander, which were passed by order of the emperor, by which the breaking out of the War of the East in 1825 he was sent on a mission to London; after a stay of only a few months he returned to his former post at Paris; but he was soon sent back to Petersburg from the land to which he had been sent, to the Great Britain. According to M. Capefigue, he felt this appointment as both a mortification and a disgrace, and it affected him greatly: but M. de Nessebois consoled him
claims for wages, each year's wages running a separate pre-
scription, and ceasing to be extant, if not pursued for,
in the lapse of three years from the time when it became due.
PRESENTATION TO A LIVING. [ADVOWSON, P.C.] PRINGLE, and
OF A BILL OR NOTE. [BILL
OF EXCHANGE, P.C.]
PRESS, BRAMAH'S, OR HYDRAULIC. [HYDRAU-
LICS, P.C., p. 384; BANDANAS, P.C.S., p. 169; OILS,
MANUFACTURE OF, P.C.S., p. 374.]

PRESS, P.C., p. 111; OILS, MANUFACTURE OF, P.C.S., p. 374.]
PRESS, LIBERTY OF THE. [CENSORSHIP, P.C.S.]
PRINGLE, THOMAS, was a powerful advocate of arts of Com-
bridge and a fellow of King's College; and he was afterwards
created a doctor of law and master of Trinity Hall. In 1564
he acted with great applause before Queen Elizabeth, in
Rightside's Latin play of Dido. About the same time, or
a little earlier, he wrote 'A Lamentable Tragedy, mixed
full of pleasant mirth, containing the life of Cambises king of
Persia, &c., and last of all his odious death by God's justice
appointed: done in such order as followeth.' This rude and
imperfect old piece is curious from its early place in the history
of the English drama; but its tumidity made it a fair mark
for Falstaff in proposing to be tragic in 'King Cambises' ve
play, printed from the undated edition, in Hawkins's 'Origin of the English Drama,' 1773.
PRIMULA, a genus of plants belonging to the natural
order Primulaceae. It has a tubular 5-cleft calyx, a silver-
shaded leaf, a long, slender, spreading limb in 5 rather deeply heart-shaped obtuse
segments; a free 1-celled ovary, with a free central placenta.
It has a capitate stigma and 1 style. The fruit is a capsule
with 5 long spreading seeds.

P. vulgaris, Primrose, is one of our commonest British
plants. It has oblong, ovate, wrinkled crenate leaves; single
flowered scapes and a tubular calyx; linear, lanceolate, atten-
uated tooth very acute; the limb of the corolla flat. It is
found in woods and thickets, and is one of the earliest of our
spring flowers.

P. dioica, Oxlip, has ovate leaves contracted below,
without the denticulate, many-flower umbellate scapes, a
pulvinar calyx; lanceolate acute tooth; the limb of the corolla
concolor, with cordate ovate segments; nodding flowers and
effect fruit. It is found in woods and meadows, but rarely in
England.

P. sericea, Cowslip, has ovate wrinkled crenate leaves,
contracted below, many-flowered umbellate scapes; a bell-shaped
calyx, rather downy, with short ovate teeth; the limb of the corolla
concave, or cup-shaped; a deeper yellow on the upper
side, with 5 orange spots. It is found plentifully in
meadows and pastures in England. The flowers possess well-
marked dark lips, and are very showy. They make a pleasant
grove inside a tubercle. The fresh root has also a smell resembling
anise, and was formerly employed as a tonic medicine and
also as a diuretic.

P. scotica is distinguished by its more ovate lanceolate
leaves, oblong ovate calyx, linear teeth, and obcordate
segments rounded below, distant, and as long as the tube. It
is found in the North of England and Scotland, and is called the
Bird's-eye Primrose.

P. auricula is found only in the North of Scotland. It
is known by its swollen calyx, with short ovate obtuse teeth;
it is a crenate, and is adapted to make a pleasant
flowering scapes. The flowers are of a bluish purple colour with a yellow core.
The leaves of P. auricula are used in the Alps as a remedy
for coughs. Swine are the only animals that feed upon any of
the leaves, as they are expressly unpalatable. They are
valuable chiefly on account of their beautiful appearance and
their early blossoming.

(Lindley, Vegetable Kingdom; Lindley, Flora Medica;
Balfour, Outlines of Botany; Balsington, Manual of British
Botany.)

PRINGLE, THOMAS, was born January 5, 1789, at
Blacklaw, in Tiviotdale, Scotland. His father was a respect-
ably well-to-do merchant. Pringle was then very young, was dislocated at the hip-joint by an accident,
which the nurse imprudently concealed till reduction was no
longer practicable, and he was thus obliged to use crutches
for nearly two years. In his seventh year he was sent to
school at Kelso, and three years afterwards went to Edin-
burgh to complete his studies at the university; after which
he became a clerk to the Commissioners on the Public Records
of Scotland. His employment was merely that of copying
old records, and his salary was barely sufficient for his humble
wants.

In 1811 Pringle and a friend published a poem called 'The
Institution of Music'; and the friend, being disposed to have
them some praise but no profit. In 1816 he was a con-
tributor to 'Albyn's Anthology,' and the author of a poem in
the 'Poetic Mirror,' called 'The Autumnal Excursion,'
which was written by Robert, and was the origin of Pringle's
acquaintance with him. About the same time he was busy
with the project of establishing a magazine as a rival to the
'Scott Magazine,' and when his plan was pretty well ad-
vanced, he was informed that his works were not so much read as he could suppose if his project was unsuccessful. Among his
coadjutors were Lockhart, Wilson, Cleghorn, Dr. Brewster,
and Hogg. Early in 1817 the 'Edinburgh Monthly Magazine'
appeared, of which Pringle was the editor. His most
important contribution to the first number was an article on
the Gipae, the chief materials for which were furnished by
Scott, unasked for and gratuitously, and which Scott had
himself intended to work up into an article for the 'Quarterly
Review.' About the same time Pringle became editor of the
'Edinburgh Star' newspaper. The magazine soon fell into
the hands of other proprietors, and changed its title to that of
Blackwood's Magazine.' Pringle still continuing to be the
editor, at the same time that he became joint editor of 'Con-
stable's Magazine'; but disputes between Pringle and Black-
wood led in a short time to a separation. Before this un-
toward event took place, he had married. Soon after, he
published 'The Excursion, and other Poems,' with little
or no profit. The editorship of 'The Star' newspaper
was unprofitable, and he resigned it; and he probably
derived little comfort from it. Constable's Magazine, in 1819,
was again on his former seat in the Register Office, performing
the laborious drudgery of a copying clerk to the
Reverend Commission.

Meanwhile Pringle's four brothers, all of whom were farmers,
had become more or less unprosperous, and he proposed
that they should avail themselves of the government scheme
of colonizing the unoccupied territory at the Cape of Good
Hope. One of the brothers had previously made a tour to the
United States of North America. The other brothers agreed to
his proposal, though the eldest brother could not get his affairs
arranged in time to accompany them; but he promised to
follow them, and Pringle undertook the management of his
farm till his arrival.

The party of twenty-four persons, consisting of twelve
men, six women, and six children, was set sail at the
Cape of Good Hope in April, 1830. On the 21st of
June they reached Rooiwal, on the Great Fish River, and
after a toilome march of some days arrived at their place of
destination. Pringle was the representative of the crown in the
colonies, and was appointed to examine the state of the
small colony, having surmounted the first difficulties, became
more prosperous, and finally arrived in July, 1833. He
resigned his farm, and went to seek employment at Cape Town, as
had been his original intention. Scott, Sir John Macpherson, and others, had exerted
their influence with the colonial secretary, and Pringle was
offered and accepted the situation of librarian to the govern-
ment library. The salary was only 75l. a year, but afforded
a fair ground-work of income to a working literary man. He
at first received pupils for private instruction, and then, in
conjunction with the Rev. Mr. Faure, a Dutch clergyman of
the town, made arrangements for the publication of a
periodical in English and Dutch. Lord Charles Somerset, how-
ever, who was one of Pringle's most ardent supporters, in
1833, would not permit any journal to be published except
the Government Gazette. Pringle was obliged to submit,
and wait the arrival of commissioners, who had been sent out
by the British government to examine the condition of the
colony. The commissioners, when they arrived, approved
of his plan; but their powers did not extend beyond that of
making a report to the home government.

Meanwhile Pringle's right limb, when with his friend Mr.
Fairbairn, who had followed him from Scotland, organized
a private academy on an extensive scale, which was prosperous
beyond their expectations. While occupied with this new
business, Pringle still continued to examine into the state of the
government from the governor authorizing him to commence his periodical, the
colonies, which, it seems, had met with the approbation of
Lord Bathurst, who was then colonial secretary.
The 'South African Journal' forthwith appeared, one edition in English and one in Dutch. Soon afterwards, Mr. Greig, a printer, commenced the 'South African Commercial Advertiser,' a weekly newspaper, of which Pringle became the editorial writer, as well as the editor. The two works were prosperous, the pupils of the literary incipient, and Pringle fancied himself about to make a rapid fortune.

A man of the name of Edwards was tried for a libel on the governor, and the trial, like others, was expected to be reported. On this occasion, however, the Fiscal was ordered to proceed to the printing-office, and assume the office of censor of the press. Pringle states that everything likely to be personally offensive to the defendant had been carefully excised, but he refused to submit to this assumption of arbitrary power, and having no legal means of resistance, threw up his editorialship. Greig discontinued the publication of the journal, to the great regret of his readers his intention of appealing to the British government. Greig's press was immediately ordered to be sealed up, and himself commanded by warrant to leave the colony within a month. The Fiscal at the same time assumed the censorship of the Magazine also, stating that if he had been aware of certain paragraphs in the second number he would have expunged them or suppressed the numbers. Pringle declared his right of censorship as a printer, and the hardy species of Pringle who stood alone, the 48th continuity of the work in the Gazette. A petition to the king in council was got up by the respectable inhabitants, and the governor became alarmed. He summoned Pringle to appear before him, and had the churlish justice, at first attempted to bully Pringle into submission, and, failing in that, tried to exjole him, and bring him over by flattery; Pringle, however, resolutely refused to recant, or conform, and the presses were ordered to be closed until the law, and not the press, should not be interfered with except by legal process.

To this the governor would not agree, and Pringle retired, and immediately resigned his appointment as librarian. The result was that the government, in order to save face, finding himself ruined in circumstances and prospects, deemed it prudent to leave the Cape, and in July, 1836, arrived in London. He applied to the government for compensation for his loss, which he estimated at £600. Meanwhile, he was engaged as secretary to the Anti-Slavery Society, a situation which he held till slavery was abolished; he became the editor of 'Friendship's Offering,' wrote and published a 'Narrative of a Residence in South Africa,' and contributed to the chief periodical works of the day.

In June, 1834, Pringle wrote to his doctor, to say, that in taking supper a crumb of bread passed down the windpipe, and brought on a violent fit of coughing; that a little blood flowed, which however soon ceased; but that in the morning he felt a sensation as if there had been some slight abrasion of the part. This slight abrasion seemed to have produced concomitant symptoms, and he felt himself becoming familiar with a warmer climate afforded the only chance of saving his life. He was preparing to return to the Cape, and had actually engaged a passage for himself, his wife, and her sister, when he received a letter from the ule of the weak state of body, occasioned his death, December 5, 1834.

The greater part of Pringle's works probably consist of fugitive pieces written during the time when he was secretary to the Anti-Slavery Society; but his reputation as a poet depends mainly on his 'Narrative' and his 'Poems.' His 'Narrative' is very entertaining; somewhat diffuse perhaps, but simple, distinct, and effective, interspersed with passages of picturesque power and beauty, and characterized throughout by the appearance of unassuming truth. He published also an 'Account of English Settlers in Albany, South Africa,' 12mo. His poetry has great merit. It is distinguished by elegance rather than strength, but he has many forcible passages. The versification is sweet, the style simple and free from all superfluous epithets, and the descriptions are the result of his own observations. His 'African Sketches,' which consist of poetical exhibitions of the scenery, the characteristic habits of animals, and the modes of native life in South Africa, are alone sufficient to entitle him to no mean rank as a poet.

PRINOS (πρίνως is the Greek name of the Holly, which the present genus much resembles), a genus of plants belonging to the family Rosaceae, flowers, a permanent half 6-clawed calyx, a rotate 6-parted corolla, 6 subulate erect filaments, a short style with an obtuse stigma, and a berry with 6 stomes. The species are shrubs with alternate deciduous or permanent leaves. P. verticillatus has oval deciduous acuminate leaves, serrated, pubescent beneath; small white flowers in little imperfect axillary umbels, which are nearly sessile. The calyx is small, 6-clawed, and persistent; the petals monopetalous, spreading, without a tube, the border divided into 6 obuse segments. The fruit is a bright scarlet, roundish, supported by the persistent calyx and crowned with the stigma, 6-celled, containing 6 long seeds which are convex outwardly and sharp edged within. The bark is very bitter, and has been substituted for Cinchona bark in cases of fever. Dr. Meere and other European practitioners employ it as a tonic in cutaneous disorders and in cases of gangrene. The berries are said to be tonic, and Bigelow asserts that they are emetic.

P. plebejus, Glabrous Winter Berry, has rather pubescent branches, evergreen cuneate lanceolate coriaceous smooth shining leaves, a little toothed at the apex; the pedicels are axillary, usually solitary, for the most part 3-flowered. It is native of North America from Canada to Florida. The berries are black, and are called in Jersey Ink Berries. It is a low handsome shrub, and is said to be one of the plants the leaves of which are sometimes used instead of Paraguay Tea. The leaves of a number of trees of the Eucalyptus genus are evergreen, and will thrive in any common light soil, but they prefer peat. They are readily propagated by laying down the shoots or by seeds. The stove species will grow well in a mixture of loam and peat, and ripened cuttings will root in sand under a hand-glass in moderate heat.

(Don, Gardener's Dictionary; Lindley, Vegetable Kingdom; Burnett, Outlines of Botany.)

PRINTS AND DRAWINGS. [COPYRIGHT, P.C.] PRISMATIC TELESCOPE AND SEXTANT. Instruments bearing these names were invented by Professor Amici, at Modena, and the former is briefly described by Sir John Herschel in the Treatise on light in the Encyclopaedia Metropolitana.' In its simplest form it consists of two pairs of triangular prisms of glass, each pair being such that an object seen through the two shall be free from colour. In order to understand its construction, let ABC, DEF, in the plane of the paper, be the principal sections of the prism, and let P and Q be the oblique objects to be rendered perpendicular to the paper, so that the sides which pass through P and Q perpendicular to the paper may be parallel to the refracting edges of the prisms; also let the eye of the spectator be situated at E, in such a position that the light falling on the surface of the square will, after refraction in the prisms, produce in the eye an image of a rectangular form, having the breadth in the direction of PQ greater than the length perpendicular to the paper being smaller. If now the rays emergent from the second prism be made to pass through two others similar to ABC and DEF, but having the plane of their principal sections perpendicular to that of the former prisms, the visible image of the square on PQ will have the length perpendicular to the paper increased as much as PQ was before increased while PQ retains the magnitude which it had acquired. Thus, after refraction through four such prisms, the image of an object is equally magnified in every direction, and is quite free from colour: and it is easy to perceive that by suffering the rays of light to pass through other systems of prisms, similarly formed and disposed, any required degree of magnification may be produced.

Sir John Herschel conceives that a telescope of this nature might be used with advantage for viewing bright objects, as the sun, since it would require no darkening glasses, and would be exempt from all the inconvenience which opposes the perfection of telescopes of the usual construction when applied to this particular purpose.

An optical instrument, which is also called a prismatic telescope, has been devised by placing between the objective and its focus two prisms of a doubly refracting medium; thus producing two images of an object, which being by moving

Vol. II.- 2 M

P. C. S., No. 142.
the prisms, made to approach to or recede from one another, permit the instrument to be used as a micrometer. It was invented or improved by M. Rochon, and is sometimes employed for the purpose of ascertaining the magnitudes of terrestrial objects, after the positions of their disks have been made to coincide in measuring small angular distances in the heavens.

The two prisms may be of Iceland spar, or rock crystal, and each is cut in the form of a wedge whose principal section is a right angled triangle, as ABC or A'BC, and the two are applied in contact with each other as in the figure. The prism on ABC is cut so that, AB being the axis of the natural crystal, the face passing through AC perpendicularly to the paper may be perpendicular to that axis; and the prism on A'BC so that the edge passing through B perpendicular to the paper may be the axis.

Now, if rays of light fall perpendicularly on the surface which passes through AC perpendicularly to the paper, those which, as ob, suffer the ordinary refraction, will leave, on passing through the double prism and also on emerging from thence on the surface passing through A'B', the same directions as they had at their incidence on the opposite side; while the rays which, as od, suffer the extraordinary refraction will, on arriving at the surface passing through BC, be turned from the original direction and take some other direction as ef towards B or A according as the crystal is of the kind called attractive or that which is called repulsive (suppose the former); then, on emerging from the surface standing on A'B, the rays will proceed in some direction as fs, if as they came from points corresponding to k in the rays produced, and will cross the ordinary rays in points corresponding to x. An eye placed near s so as to receive the rays of both kinds will perceive two images of the object from whence they proceeded before they fell on the prism. The constant angle at which the rays are inclined to another is measured by ach, k being in the direction of ef produced; and when the prism is of Iceland spar the angle ach may exceed 45 degrees; when of rock crystal it may amount to 10 degrees.

Let the double prism be placed between the object-glass O of a telescope and its focus, the face standing on AC being towards the former and perpendicular to the optical axis; and for simplicity, let the object be a straight line XY in a vertical position having one extremity X in the axis OE: then x and y being the foci of pencils diverging from X and Y, after being refracted through the object-glass O, the line xy may represent the image of XY formed as usual by the ordinary rays in the pencil of light, and xy'f, in a vertical line passing through xy, the image produced by the extraordinary rays; the angle \( \alpha x y' \) or \( y'k y \) being that which was denoted by ach above. Therefore, if the angular deviation of the images produced by the two kinds of rays is small enough to permit the rays to enter the eye near E, after passing through the eye-glasses of the telescope (the angular deviation not being altered by the refractions in those eye-glasses) corresponding points in the two images will in general appear to subtend some angle at the eye. If the points a and A' in the prism are at the foci x and y of the object-glass, the two images of XY will evidently coincide; but, on moving the prisms so far that the images will in general appear to subtend another angle, the angular deviations being proportional to the distance of A' from x.

Now, on the exterior of the telescope in a direction parallel to the axis, there may be formed a scale which, by means of an index moveable with the prisms, will serve to measure any subtended angles; thus:—The angle subtended at the naked eye of the observer by any object as XY, which may represent a straight line or the diameter of a circular disk, being less than the constant angle \( \alpha x y' \), there will be found a certain position of the prisms at which one extremity Y of the line or diameter seen by the ordinarily refracted rays will appear at a common distance from the observer; it has been also used in measuring small angular distances in the heavens.

The Prismatic Sextant, invented by Professor Amici, is described in Zach's 'Correspondance Astronomique,' tom. vi. p. 554. It has no mirror, but, nearly at the place where the index-mirror is situated on a common sextant, there are two triangular prisms of glass whose parallel edges are perpendicular to the face of the instrument. One of these is fixed, and the other turns on one of its edges by the motion of the index-bar, the broadest faces being parallel to each other, and nearly in contact when the index is at the zero of the arc: the telescope is fixed, and rests on a pivot near the objective; the light falling on the exterior faces of the prisms will, after two refractions and one reflexion, and after passing through the telescope, enter the eye of the observer, so that, by moving the index-bar, the angle in the index will be divided into a number of equal parts corresponding to the difference between those angles, and the divisions be continued in opposite directions, there will be constituted the required scale, by which the angle subtended when the images of any other line or disk are placed in contact, by moving the prism, may be measured.

The Prismatic Sextant, invented by Professor Amici, is described in Zach's 'Correspondance Astronomique,' tom. vi. p. 554.

PRISTACANTHUS, a genus of fossil placoid fishes, from the colli of Stonesfield. (Agassiz.)

PRISTIS. Three species of this genus of fishes are menioned as fossil in the tertiary strata of England. (Morris's Catalogue.)

PRIVY SEAL. [Signet, Seal, P.C.] The Lord Keeper of the Privy Seal is a member of the Cabinet, and has a salary of 5000l a year. By an Act of 1845, however, the Commissioners of the Treasury may abolish any of the offices of Clerks of the Signet and Privy Seal when they become vacant, and direct the duties to be performed by the remaining clerks.

PRIZE-MONEY. [Prize-Money, P. C.] Appraisments and sales of prize and capture are made by agents appointed by the commanders and other commissioned officers. A certified list of the persons entitled to share in the capture is transmitted to Chelsea Hospital by the commanding officer. There is a penalty of 500l for altering names. At the end of three months from the receipt of prize-money, the treasurer of Chelsea Hospital is to notify to the 'London Gazette' and in two London morning papers that distribution will be made at the end of one month. In this notification the share of an individual in each class must be declared. Shares of prize-money due to a non-commissioned officer or soldier, will be paid only upon personal application, or to his wife, or child, father or mother, brother or sister, or to the regimental agent of his regiment, or to any other regimental agent. The payments are to be made at Chelsea Hospital, by appointment, signed by the clergyman and one of the churchwardens or overseers. Personating or falsely assuming the name and character of a person entitled to prize-money with fraudulent intent is made a misdemeanour with transportation for seven years. By 3 & 4 Vict. c. 65, the Privy Council may refer to the High Court of Admiralty matters concerning poverty and the capture of prize-money.
PRO

PROBATE AND LEGACY DUTIES. These duties yield a sum exceeding two millions a year. The legacy duty is charged on legacies of the value of 20l. and upwards out of personal estate, and is charged on every share of residue. Legacy to a husband or wife is exempt from duty. To a child or parent, or any lineal descendant or ancestor of the deceased, the duty is 1¼ per cent.; to a brother or sister or their descendants, 1½ per cent.; to a great uncle or great aunt or their descendants, 2½ per cent.; to any other relation or any stranger in blood, 10½ per cent. The probate duty is payable by the executors, on or before 5th April in the year succeeding the death. For sums above 20l. and not exceeding 100l. the duty is 10s. if there is a will; and if there is no will the duty of 10s. is chargeable on sums of 20l. and not exceeding 50l. The duties continue to increase according to a certain scale up to 1,000,000l. The following tables show the operation of the legacy and probate duties for nearly half a century; and in Foster's 'Progress of the Nation,' vol. iii., pp. 125-139, will be found some useful and interesting considerations on these duties as indications of the progress of national wealth:

PRO/CULIS, a distinguished Roman jurist, the successor of Nerva the father. He belonged to the school of Laber, and in the followers of whose school he was instructed from him. [Lamb, Antistius, P. C. S.] It is generally stated that his name was Sempronius Proculus, but Pomponius (Dig. 1, tit. 2, s. 2, § 47) calls him simply Proculus. The passage of the Digest (31, tit. 1, s. 47) which is cited to prove that his name was Sempronius does not prove that it was. In this passage Sempronius Proculus sends greeting to his grandson, and asks him his opinion about a legacy. Proculus responds. Proculus gives his opinion, and therefore the grandson and Proculus are the same person; and as Zimmern remarks, Proculus the jurist might be the son of the daughter of Sempronius Proculus the grandfather, in which case his name has been met with in another form, and has been corriged. The name of Proculus the jurist is the Licius Proculus whom Otho made Praefectus proctorio (Tacitus, Hist. i. 46, 87, ii. 39, 40, 44, 69). Proculus is often cited in the Digest, and he is apparently mentioned in a Description of the Divi Lex in an eminent authority (Dig. 17, tit. 14, s. 17). There are thirty-seven excerpts in the Digest from a work of Proculus, entitled Epitome, of which there were at least eleven books (Dig. 18, tit. 18, s. 69), though the Florentine Index mentions only one. Of the excerpts (Dig. 33, tit. 6, s. 16) has the title 'Proculus, libro iii. ex Posterioribus Labonis,' which appears to be a separate work or a separate edition of the works of Labonis. But as Javolenus wrote on the Posterioria of Labonis (Dig. 33, tit. 7, s. 4), it is conjectured that the title of s. 16 (Dig. 33, tit. 6) should be 'Javolenus.'

(Grotius, Vita Jurisconsultorum; Zimmern, Geschichte des Römischen Privatrechts, p. 816.)

PRODUCTUS, the original name given by Sowerby to a large group of fossil Brachiopoda, most frequently found in the mountain-limestone series. Productus and, for part of the group, Lernaria are described in this work.

PROLAMINATION. Prolamigation is from the Latin promulgant, which is equivalent to promulgata, and means 'to make public.' The modern sense of Proclamation of a Law is the making of it public by giving notice of its contents to the public in any way or other. Blackstone observes (Comm. i. 45), 'It may be notified by universal tradition and long practice, which supposes a previous publication, and is the case of the common law of England.' The proclamation may be notified once by officers appointed for that purpose, as is done with regard to proclamations, and such acts of parliament as are appointed to be publicly read in churches and other assemblies. It may lastly be notified by writing, printing, or the like, which is the general course taken with all our acts of parliament.' A law is a command from a political superior to a political inferior to do or not to do something, with a penalty attached to the violation of the command, and it is assumed by Blackstone that the command is made known in some way to all who are bound to obey it; or it is presumed that it is known to all. But as to 'a universal tradition or long usage,' it is a mistake to say that it supposes a previous publication. A long usage does not of itself make law; the usage must be pronounced to be law by some competent authority, and that is the only proclamation which it has. Proclamation by proclamation is inadmissible (Blackstone). It only reaches those who hear it. Further, everybody cannot hear an act of parliament which is read in churches, for the churches would not hold one-fourth of the people if they all went to hear it read. If it is said that they heard it and understood it. Printing is at present the most efficient means of promulgating a new statute; but to all those who cannot read it is ineffectual; and also to those who cannot understand it.

No remedy can be provided for these difficulties, and it is simply a positive rule of law that a new statute is binding on all persons who are under the authority of the power which makes the statute, even when the moment that the statute was made and completed in due form. It is a foolish way of speaking to say that a person is presumed to know a law, when it may be very easy to show in many cases that he did not know it and could not know it. One kind of legal presumption consists in the assumption of a fact, which presumption may be disproved by evidence. But the presumption that a man knows the law is not an assumption which a man is permitted to disprove even if he can, and this presumption should be struck out of the list of presumptions and placed among positive rules of law.

If a man were allowed to urge ignorance of law as an excuse, it might be urged by a great majority in many matters of contract and in other cases too; and the trial of the fact of ignorance of law would give ample room for fraud. The positive rule that all the members of a state are bound by its laws, causes less evil than the admission of the excuse would have. Proclamation of a law among the Romans meant the placing of the bill (regation) in some public place where it could be read before it was voted upon in the Comitia. The Roman rule was that ignorance of law (ignorantia juris) was no excuse. (Paulus, Dig. 22, tit. 6, s. 3.)

PROPERTIES OF IRON, MEDICAL. Iron, in a purely metallic state, does not exert any appreciable influence over the human system. Nevertheless metallic iron is recommended as an antidote to poisoning by the salts of copper. Iron filings have been administered with a view to precipitate the copper in a metallic and therefore in an innocuous state. White of egg is a more prompt and generally more accessible antidote. The employment of iron filings to absorb forbid earlier calculations from the skin and the lungs, while recently prepared and freshly powdered charcoal, put every morning into the shoes of those afflicted with this annoyance. Iron filings are sometimes prescribed, but before any marked effect can be produced by them, the metal must become an oxide or a salt; the presence of any acid in the stomach or alimentary canal promotes this change, while alkalis retard it. This form has been adopted in the treatment of worms, chiefly from the notion that the worms would be dislodged by the mechanical irritation of particles of iron. This is an erroneous view. [Asthenismus, P.C.] Tincture of sesquisulphide of iron in infusion of quassia is extremely

3 M 2
beneficial in all cases of worms, but its efficiency depends on its tonic and astringent properties.

A few only of the preparations and uses of iron can be given here. Sesquioxide of iron (rust, or the subcarbonate of sesquioxide of iron) has been given as a tonic in very large doses; in some instances with success. It is likewise useful in some cases of spasmodic contractions of the joints. The very large doses in which it is required to be given is a serious impediment to its use; for not only are patients adverse to it, but it clogs the intestines, which require to be frequently cleared out by a brisk cathartic.

The black oxide is not so liable to objection, as it is more readily soluble in the fluids of the alimentary canal.

Ammonio-chloride of iron possesses no advantage over the simple chloride; the tincture of which, called tincture of sesquichloride of iron, is extremely valuable, as an emmenagogue; it likewise is very beneficial in checking menstruation proceeding from relaxation of the uterus. It checks haematuria from relaxation of the tissue of the kidneys. In frequently repeated small doses it relaxes spasmodic stricture of the urethra. But the sense of nausea and sickness which it causes, renders patients averse to its repetition. It acts as a potent astringent when employed externally or to mucous membranes as an injection.

Sulphate of iron can be given in small doses, in pills or otherwise. Its powers are often much heightened by combination with sulphate of quina. In nervous debility and indigestion it is valuable.

Ferro-tartrate of iron has less unpleasantness of taste than most of the other preparations of iron, and is therefore more acceptable to children, to whom also the vinum ferri is much preferred. These doses are nearly supplied by the chloride, or ammonio-citrate of iron, which can be given in the form of lozenge or syrup. The latter given in warm water or lemonade is relished by most children.

Isolde of iron is a preparation of great value in strumous disorders.

The same may be said of the phosphate of iron, a preparation formerly in the London Pharmacopoeia, and now most admirably performed. In the phthisic diathesis, in feeble subjects, with a tendency to rickets, it is invaluable. The dose for children is a very few grains, cautiously increased. The numerous preparations of iron recently introduced by chemists have not been sufficiently tried to permit them to be spoken of with certainty; but in many cases their utility is obvious. Of these the chief are citrate of iron, Potassio-citrate, Sollio-citrate, Zinco-citrate, Magnesio-citrate, Ferrico-citrate, and Citrate of quinine and iron; this last is of great service in tic douleureux.

Chalybeate waters often furnish the best medium for administering iron; especially when the iron is associated with an acid of tonic action. Where no free carbonate is present, and in some instances even where it exists, the water of the springs should be received in and drunk out of warm water. This often prevents the spasm which is apt to occur when the water is drunk cold, and may be the cause of the cathartic effect.

Besides being reputed an antidote to the poisonous salts of copper, iron is asserted to prove an antidote to various poisonous poisons.

Hydrate of peroxide of iron, called also hydriated peroxide of iron, is considered a trustworthy antidote against arsenic, if administered promptly, while the arsenic is yet in the stomach, and not absorbed. Prussic acid may be decomposed or combined, so as to be rendered innocuous, by giving promptly, first, solution of carbonte of potas, followed by a very diluted solution of the pro-pherulose of iron; the object is to form a ferrous subcarbonate, (See \textit{Lancet}, 5th October, 1844, or \textit{Chemical Journal.}, vol. iv. p. 373.)

\textbf{Physiological Effects and Therapeutic Employment of Iron.}—Iron exists in both plants and animals, as the mammal and birds, constituting an essential part of their fluids and solids; but, incorporated as it is thoroughly with them, it gives rise to none of those phenomena which it occasions when taken externally. Upon the living tissues iron has a tonic influence; and as its preparations greatly promote digestion, they excite the appetite and render more easy the elaboration of the aliment. The vitality of the digestive organs becomes increased from the nutritions principles, and thereby furnish a greater quantity fit to be assimilated.

These beneficial effects are best seen when the medicine is given in small and long-continued doses, or in the greatly diluted state in which iron occurs in the mineral waters or chalybeate springs. On the other hand, chalybeates occasion at times, especially if in large doses, pain of the epigastrium, nausea, febrile excitations, and great anxiety; consequences resulting from the premature production of constitative action, which the preparations of iron make or exercise when they reach the stomach, upon its internal surface, and the nerves which are distributed upon it. The unpleasant effects may generally be avoided by giving it first in very small doses, gradually increased, or by diluting it with some vegetable substance of little activity.

Iron given in large doses, when it reaches the intestines, produces in some persons obstinate constipation, accompanied with a sense of great heat in the lower belly; in others it occasions colics and frequent alvine depotions; while with a third set of persons none of these effects follow its administration.

During the use of iron the faces invariably become blackened, which is caused by the tannin of our food acting upon the iron.

In respect to the secondary effects of iron, the amount of these depends upon the quantity absorbed, and the length of time it has been given. That it is absorbed, in most instances, and carried into the circulation, is proved both by the effects of it being felt over the whole system, and by being distinctly recognizable in the urine on the addition of an infusion of galls. When used for some time, chalybeates increase greatly the power of the heart; the pulse becomes stronger and harder, and in certain cases Observable; the body increasingly enfeebled by disease. If persisted in, they cause increased arterial action, followed by feeble commotion, sense of heat, and hemorrhagic discharges from different parts of the body.

These actions are considered as indications of a phlegmatic habit and sanguine temperament; iron also rouses the absorptive organs when sluggish.

The functions of nutrition and assimilation are greatly heightened by the use of iron; but it be too long persevered in, diseases of over-action ensue, as inflammations, hemorrhages, &c. These symptoms indicate the necessity of discontinuing it.

The preparations of iron are unquestionably efficacious in diseases which proceed from a relaxation of the substance of the living tissues, from an inactivity of the reparatorii or assimilative function, or in case of weakness proceeding from deficient supply of nervous energy.

Hence they are indicated in Anæmia, in convalescence from debilitating fevers, and other tedious diseases, as well as after some of the more acute phlegmasies, as paralysis, the cough remaining after which, if not occasioned by any organic change, is sooner removed by preparations of iron or baux than by any other means. Chalybeates are likewise given in defective menstruation from dulness of the uterus, and sometimes in other cases of menorrhagia, where the sheets are required. Besides being reputed an antidote to the poisonous salts of copper, iron is asserted to prove an antidote to various poisonous poisons.

Hydrate of peroxide of iron, called also hydriated peroxide of iron, is considered a trustworthy antidote against arsenic, if administered promptly, while the arsenic is yet in the stomach, and not absorbed. Prussic acid may be decomposed or combined, so as to be rendered innocuous, by giving promptly, first, solution of carbonte of potas, followed by a very diluted solution of the pro-pherulose of iron; the object is to form a ferrous subcarbonate, (See \textit{Lancet}, 5th October, 1844, or \textit{Chemical Journal.}, vol. iv. p. 373.)

\textbf{Physiological Effects and Therapeutic Employment of Iron.}—Iron exists in both plants and animals, as the mammal and birds, constituting an essential part of their fluids and solids; but, incorporated as it is thoroughly with them, it gives rise to none of those phenomena which it occasions when taken externally. Upon the living tissues iron has a tonic influence; and as its preparations greatly promote digestion, they excite the appetite and render more easy the elaboration of the aliment. The vitality of the digestive organs becomes increased from the nutritions principles, and thereby furnish a greater quantity fit to be assimilated.

These beneficial effects are best seen when the medicine is given in small and long-continued doses, or in the greatly
main edifice and colonades within the court, and giving the exterior the aspect of a fortress,—the propylæa of the Greeks were detached structures placed in advance of the sacred edifice itself, so as to mark very conspicuously the approach to it through the outer enclosure or boundary, they seem to have been intended in some degree to prefigure the temple itself to which they conducted, their general appearance in front being almost identically the same as that of the frontispiece or pediment end of the Attic temple,—a repetition, by the by, and sameness of design do not say so much for invention on the part of the architects, or for the capability of the style employed by them to impress distinct character on buildings of both sorts, is a question which we leave to the gateway conducting to it; unless we would rather suppose that the kind of prefiguration above hinted at was not directly and studiously.

The general arrangement and character of a Greek propylæum may be described as similar to those of an amphitheatre temple [TEMPLE, P. C.], shorter however on its sides than the width in front, and without any cells; yet not entirely open to both fronts, but divided by an inner wall across it from side to side, into two portions, the outer one of which, answering to the proæmas of a temple, was larger than the other; so that the whole may be more bly, if not more intelligently explained, by comparing the plan to the proæmas and apisthodomes of an amphitheatre temple, put together without any intervening cells, being separated only by the two buildings used as many open doorways as there were intercolumnia in front.

Such was the disposition of the propylæum both of the Parthenon at Athens and of the temple at Eleusis, the only two examples I have seen of the kind. It is not however so only by the drawings of it the unedited antiquities of Athens: there were: indeed, as we learn from Pausanias (ii. 5) propylæa at Corinth, but of their architectural design we know nothing. The Athenian structure stands on the west side of the Acropolis, as may be seen by the cut in Furtwängler, P. C. (vol. vii. page 288, col. 2), which shows its relative position to the temple itself—an irregular one, the two buildings not being of the same number in the front. This propylæum, which was begun by the architect Mnesicles in the 4th year of the 85th Olympiad, and completed in five years, is of the Doric order, and hexastyle on both fronts; and the outer or western one was greatly extended by two flanking wings projecting forward at right angles, so as to enclose the platform to which an ascent of steps led up from below, and above which the portico and the two lesser colonades forming the sides of the wings were raised upon three other steps. Thus the platform (78 feet from north to south, by 40 east and west) became an elevated open fore-court, presenting a principal portico in front crowned by a pediment, and two colonades flanking it, on both sides of which the steps began (the others 28 feet high) gave greater importance to the former; and a degree of scenic effect—combination, contrast, and variety—was produced, very unusual in Greek architecture, and which would on a smaller scale have been a kind of the lower flight of steps existed, of which however there now exists no trace, they having been destroyed to make way for a Turkish battery and the approach to the Acropolis. In the second century of the Christian era that first ascent was flanked on each side by an equestrian statue (one of them conjectured by Chandler, from an inscription, to have been that of Agrippa, wherefore it is probable that the other was that of Augustus), which, though later additions to the structure, must have greatly enhanced the general appearance of the architectural ensemble.

The most remarkable circumstances which served to distinguish the Propylæa from a portico is that in the western or outer division there were two rows of inner columns placed not parallel, but at right angles to the front wall. This had the effect of dividing the plan thereby dividing the plan internally into three compartments, the centre one narrower than the other two, and forming an avenue to the principal doorway, which was the largest and longest in the whole temple, and the two end ones the smallest. These inner columns, too, instead of being of the same order as the exterior, were Ionic,—a very remarkable peculiarity, insomuch as it evidences an intention to prefigure the temple itself by the gateway conducting to it; unless we would rather suppose that the kind of prefiguration above hinted at was not directly and studiously.

The Eleusian propylæum resembled that of the Acropolis in nearly all particulars, except that it had no wings attached to it. Like the Athenian temple, it seems to have been intended in some degree to prefigure the temple itself to which they conducted, their general appearance in front being almost identically the same as that of the frontispiece or pediment end of the Attic temple,—a repetition, by the by, and sameness of design do not say so much for invention on the part of the architects, or for the capability of the style employed by them to impress distinct character on buildings of both sorts, is a question which we leave to the gateway conducting to it; unless we would rather suppose that the kind of prefiguration above hinted at was not directly and studiously.

As modern structures presaging of the ancient Greek propylæum character, may be mentioned Capua's Porta Tectum at Milan [CAGNOLA, P. C. S.], and the London Terminus of the London and Birmingham Railway, in Euston-square, which, though only a distyle in antis in both fronts, is a structure which might be said to conduct to the gateway to an unexpected normal.
PRUNELLA, a genus of plants belonging to the natural order Labiate. It has two inferior stamens. The filaments bifold, one branch barren. The anthers 2-celled. The corolla usually tubular, or the lower lip truncate, 3-toothed, the lower lip bifid.

P. vulgaris, Self-heal, is a native of Europe and Asia, very common in Britain. It is an English plant.

The leaves are stalked, ovate or oblanceolate, orifice truncate, 3-lobed, the upper lip of the calyx with short truncate mucronate teeth, the lower lip with ovate-lanceolate mucronate teeth. The stem is almost upright, glabrate, straight, and has a very strong and pungent root at its apex. The flowers are purple, white, or nearly red. In the British specimens the leaves are nearly entire. This plant is considered astrigent, and was formerly used in forsythia for asthma and inflammation of the faucets. Its reputed use is now merely in name.

P. grandiflora has petiolar ovate leaves, quite entire or toothed, the lateral teeth of the upper lip of the corolla lanceolate, the corolla larger, more than twice as long as the calyx. It is native throughout Europe in woods and shady places; the flowers are of a purple or violet colour, seldom white. All the species of Prunella are showy when in blossom, and are therefore worth cultivation in flower gardens and rock-work. They grow in any common garden soil, but thrive best in a damp moss situation. They are readily propagated by seed or division.

(From Mrs. A. M. Pethick's Botany. New British Botany; Lindley, Vegetable Kingdom.)

PRUSSIC ACID—Medical Properties of. This acid, termed also hydrocyanic acid, has been described according to its discovery by Liebig in P.C.: Its employment may be described by its connection with medical jurisprudence, from the frequent use of it in cases of death, accidental or intentional, merit the most attentive consideration. But these are unsuiting for popular discussion. A few important rules and cautions can alone be furnished here.

Much variation in strength exists in the acid (that is, the dilute acid, for the anhydrous is always of definite strength), owing to the different modes of preparation, and does a difference of strength exist in the acid as it is enjoined to be prepared by the Edinburgh and London colleges, but even in England two preparations are commonly met with, that enjoined by the London Pharmacopoeia, which contains 2 per cent. of real acid, and that which has been long known as Scheele's, containing 4 per cent. The substitution of the one for the other in preparing a prescription might lead to serious if not fatal consequences. A still greater difference exists in the strength of the preparations met with in different countries of the Continent. No one in travelling should ever prescribe prussic acid, unless he has previously ascertained what preparation will be employed in compounding the prescription.

As it undergoes decomposition by time, especially if exposed to the air at a high temperature, it should be kept in the dark, and in a cool place. As it is specifically lighter than water, it rises to the surface in watery fluids. The fluid in which it is kept should be well stirred before pouring it out. When employed externally as a lotion, in which case it is used in larger doses than when meant for internal employment, great care should be observed to distinguish it, lest it should be accidentally taken internally. Even its external employment demands great care, for when the cuticle is abraded or cracked, it is readily absorbed, and may prove fatal. The cuticle, even when in a state of integrity, is not proof against the vapour of prussic acid. It is a well-known fact that the body should be kept well corked, as the vapour is the most potent form which can influence the human frame.

When first introduced into medical practice, high expectations were formed from it, but the experience of Frederick and other eminent medical men has moderated these expectations; but there is no doubt that it might be found useful in many instances where it is not employed, the dread of accidents deterring many from the use of it. It is now known that the effects produced by the vapour and the fumes are chiefly due to the action on the mucous membranes, after the active stage is passed, or those of irritation. Among the former, hooping-cough is unquestionably benefited by it. But here great caution is necessary. Its premature employment, by checking the cough, induces inflammation, often of a very alarming kind. The dose should at first be very small, and most slowly increased. In some cases, even emanating from medical men, large doses are most culpably administered. If the calyx is absent in the fre-
species are small trees or shrubs, natives within the tropics; they are very numerous and intricate.

P. erectus has a hemicryptophyte, stemmed branched root with a slender axis, and a thick friable back. It is an erect simple hairy under-shrub, with oblong acuminate leaves narrowed at the base, membranous ciliated, rather phloifaceous; stipules short, bifoliate, the flowers 2-4 in a fascicle, sessile, bracteolate, terminal, and axillary. This species is accounted poisonous in Brazil; it is known by the name of Erave de raiz, and is used for the destruction of rats and mice.

P. speciosa is employed in Brazil in the same diseases as sarsaparilla; and P. tinctoria forms a fine red dye much valued in Peru. All the species of Psychotria are of most easy culture and propagation. They grow best in a mixture of loam, peat, and sand, and cuttings will strike root readily if planted in sand underneath a glass-frame. Some of them bear handsome foliage, but the flowers of all are insignificant.

(Don, Gardner's Dictionary; Lindley, Flora Medica; Lindley, Vegetable Kingdom.)

PTARMICA, a genus of plants belonging to the natural order Asteraceae. It has a campanulate involucre with the scales brown and scarious at the edge. The receptacle is flat or scarcely convex, bristly, and covered with scales. The flower from 6 to 20, flat, expanded, much longer than the involucre. The achenes are bidentate, obovate, the outer one somewhat winged at the edge.

P. elegans has a widely creeping root, very difficult to extirpate when the soil is moist. Upright stems about two feet high, angular, smooth, hollow, leafy, with small axillary rudiments of branches corrymbosum at the top. The leaves are sessile, linear, or slightly lanceolate acute, very minutely serrated with bristly teeth. Smooth on both sides and a dark green. The flowers are mill-white, larger than most others of the same genus. The whole plant is pungent, and probably contains an active principle that causes irritation, but this is thought to be owing to their little sharp marginal teeth: the root is aromatic. The heads of P. nova, atrata, and moschatula are used in the Swiss Alps as a substitute for tea. Moschatula is the basis of the aromatic liqueur called Esprit d'iva.

(Lindley, Vegetal Kingdom; Lindley, Flora Medica.)

PETERCHITHYS, a singular genus of fossil ganoid fishes from the old red- sandstone of Scotland and Orkney. (Agassiz.)

PETER/NEA, a fossil genus of Conichthir, allied to Aviculo, and bitherto confined to the Palaeozoic, and chiefly found in the Devonian strata. (Goldsmith.)

PETERS (from spiras, a wing), a genus of plants belonging to the natural order Filices. The thecm arise from the points of veins placed on a nerve-like receptacle running along the edge of the leaf, forming an uninterrupted marginal sori; the involucres are continuous with the edge of the leaf, scarious, and opening inwards.

P. aquatica, common Fern, or Bracken, is the most abundant of our British species. It has a long tapering creeping rhizome, externally black. The leaves are erect, from one to six feet high, repeatedly compounded with horizontally spreading divisions, whose ribs are smooth; the primary leaves are nearly opposite, the lower ones more acute, pinnatifid segments oblong, obtuse. They are all of a light bright green colour, slightly brown at the edge, which is revolute and crispis, or wavy, sheltering the dense linear masses of tawny hairs below, the cuticle smooth, greyish, not wounding the hands severely if plucked incrustaneously. When cut across, the rhizome has a branched appearance resembling a spread eagle, whence the Latin name. There is scarcely any scent from it in the United Kingdom where this plant does not make its appearance. It is said to be indicative of poor soil, but it is more probable that its presence on cultivated ground is attributable to the effects of the frost and mildew, rather than to the quality of the soil. The geographical range of this species is very extensive; it is included in every European list, and is found also in Asia and America. It is used for thatch, for many parts of England and Scotland for manure, and in the West Indies for the same purpose.

The people gain considerable profit by collecting the leaves, and selling the ashes to soap and glass makers, on account of the large quantities of alkalies contained in them. The leaf is better for horses, braces or fern is in great request in Wales, Scotland, and Ireland, and when chopped up with hay they are sometimes fed upon it. In Invernesshire the poorer classes thatch the tops of their thatched houses with the leaves, which, although not durable covering, pigs are fed upon the roots boiled down into a mucilaginous mass. This species is the Filix fontana of our older authors. It is likewise the pteridium of Theophrastus, Hist. Pl. 9, 15, and of Dioscorides, 4, 184. The ancients are said to have used both the rhizomes and fronds of this fern in decoctions and diet-drinks, in chronic disorders of all kinds arising from obstruction of the visera and spleen. Some modern authors give it a high character of the same property, but it is now seldom used by medical practitioners. In haller's time its reputation was very extensive as a destroyer of worms, and a bed of the green fronds was esteemed a sovereign remedy. It is said in children to be astringent that in some places it is used for tanning and dressing red and chamois leather. It has been employed as a substitute for hops, and in the Canaries a miserable sort of bread is made from it. The root is still used in decoctions.

(NEWMAN, British Ferns; Babington, Manual of British Botany; Lindley, Flora Medica.)

PEROCATRUS (from spiras, a wing, and adraps, a fruit, in reference to the pods being girdled with a broad wing). It has a 5-cleft calyx, a corolla with 5 petals, disposed in a papilionaceous form; 10 monadelphous or diadelphous stamens, an irregular indescriptive legume, somewhat globular, surrounded by a conical scale, the calyx of the middle 3-celled. The leaves are unequally pinnated. The racemes axillary, or forming terminal panicles. The species are unarmed trees or shrubs.

P. Draco, Dragon's blood Pterocarpus, is a tree nearly 30 feet high, with alternate shining leaves, about 5 on each side, and an odd one, rather obtuse, entire, veined, smooth, pale green below; the legumes nearly smooth. The wood of this tree is white and heavy, the bark thick and of a rustcoloured, grey colour. When first cut it presents no marks of redness, but in a little time red drops of juice begin to collect and exude from the wood. If left in the sun for about ten minutes and clear, and collected, it is called the dragon's blood, and is obtained from the leaves of sanguis draconis, or dragon's-blood. This resin formerly constituted an extensive article of commerce from Carthagena, but from its diminished consumption its collection has ceased. The dragon's-blood obtained now in the market is the produce of Calamus Draca.

P. sanguinum is a tree with a very high trunk, scarcely ever found straight. The bark has a brown outer coat which is thin and spotted with black dots in flakes, the inner bark, which is flabby, red, and astringent. The branches are numerous, horizontal, and spreading. The leaves subbifarious, alternate, pinnate, with an odd one, 8 or 9 inches long. The panicles are terminal and very large, ramifications bifarious. The flowers are very numerous, white, and with a small spot of yellow in the centre. The bracts small, caducous, solitary below each division and subdivision of the panicle. The seed is solitary and kidney-shaped. This tree is thought by Roxburgh to be the one yielding gum hino, a well known astringent,—the juice hardening into a dark red and very brittle gum resin, which, on being powdered, changes to a light brown, not unlike Peruvian bark. Its taste is strong, but simply astringent. The real kino-tree however appears to be the next species.

P. erinaceus is a tree 40 or 50 feet in height. It has uniquely pinnate leaves, smooth above, downy beneath; from 11 to 15 leaflets, alternate, distant, on short stalks, ovate, oblong, obtuse, or margined, wavy at the edge; lanceolate stipules, solitary or clustered racemes, downy from the old wood below, the cuticle smooth, greyish, not wounding the hands severely if plucked incrustaneously. The flowers are yellow, the legumes stipulate, compressed, membranous, velvety, serrated, and undulated, prickly on the centre. When the branches are wounded, a clear bright red gum exudes from the inner me, and is mentioned as such by Mr. Mongio Park. It is
a very powerful remedy in obstinate chronic diarrhoea and dysenteries, and in all diseases arising from laxity of tissue. In many cases it is applied as a purgative to check hemorrhage from wounds and ulcers, and to diminish discharges.

P. sanctusibus is a lofty tree having alternate stalked leaves, peltate alternate, leathery, smooth above, and untoothed beneath. The flowers are axillary, solitary, or branched, and erect. The legume roundish, stalked, falcate upwards, compressed, smooth, keeled on the lower edge, the keel being somewhat bifurcated. From its colour the wood is obtained. The Red Sandal-wood, a timber chiefly used by dyers and colour manufacturers of the present day, but which is also used to colour several official preparations, such as compound tincture of mercurial water forms, its beautiful coloured precipitates with many metallic solutions.

P. flavus is the yellow sandal-tree, and is used for dyeing yellow. Its bark is very bitter.

The species of this genus thrive best in a loamy soil, and young cuttings not deprived of their leaves root readily in sand under a glass in heat.

(Dorn, Gardiner's Dictionary; Lindley, Flora Medica; Barnett, Outlines of Botany.)

PETROPHIUS, a genus of fossil Cyczandaceous plants from the oolite of Yorkshire and beds of the same age in Scania. (Brongniart.)

PETIOLO DORSUM, a genus of fossil corals from the Silurian strata of Salop, Westmoreland, and Tyne. (Loudon.)

PETRACANA THUS, a genus of fossil placoid fishes from the old red and mountain limestone strata. (Agassiz.)

PETRUM, 1200, a genus of Copephlopa from the fault of Folkstone. (D'Orbigny.)

PETRASCHUS, a genus of fossil fishes from the Cretonaceous system of England. (Agassiz.)

PETROYCHIUS, a genus of fossil ganoid fishes from the Eias of England, &c. (Agassiz.)

PUBLIC HEALTH. On the 14th May, 1838, the Poor Law Commissioners presented to Lord John Russell, then Secretary for the Home Affairs, a Report by Dr. Arnott and Dr. Kay, and two Reports by Dr. Southwood Smith, relative to the prevalence of disease among the labouring classes in certain districts of the metropolis. The House of Lords having, on the 16th of August, 1839, presented an address to her Majesty requesting her to direct an inquiry to be made as to the extent of the causes of disease mentioned in those Reports, the Poor Law Commissioners received a letter from Lord John Russell, in which he stated that her Majesty required them to make such inquiry, not only as to the metropolis, but as to other parts of England and Wales, and to prepare a Report stating the result of such inquiry.

In 1840 the subject was investigated by a Committee of the House of Commons, the result of which was a Report 'On the Health of Large Towns and Populous Districts.' In 1842 a Supplementary Report on the Sanitary Condition of the Labouring Population of Great Britain, by Edwin Chadwick, Esq., 'Local Reports on the Sanitary Condition of the Labouring Population of England,' were presented at the same time. Of these local Reports there were twenty-six, some of which relate to certain counties and others to particular towns. At the same time were presented Reports on the Sanitary Condition of the Labouring Population of Scotland.' In 1843 a 'Supplementary Report on the Results of a Special Inquiry into the Practice of Interment in Towns,' by Edwin Chadwick, Esq., was presented. On this subject see some remarks under INTERMENT, F. C. S.

On the 9th of May, 1843, Commissioners were appointed by the Queen for the purpose of 'inquiring into the present state of the working population of the various districts in England and Wales, with reference to the causes of disease among the inhabitants, and into the best means of promoting and securing the public health, under the operation of the laws and regulations established for the purpose at present prevailing with regard to the drainage of lands, the erection, drainage, and ventilation of buildings, and the supply of water, in such towns and districts, whether for purposes of health, or for the better salubrity and safety of their dwellings, may be promoted by the amendment of such laws, regulations, and customs.'

The first Report of the Commissioners was presented to both Houses of Parliament at the end of June, 1844. The report was accompanied by 437 folio pages of evidence on which the Report is founded, an Appendix of Special Reports on the sanitary condition of several towns, among the most important of which are—Liverpool, by W. H. Duncan, M.D.; Ashton-under-Lyne, by John Ross Coulthart, Esq.; the City of York, by F. W. Laycock, M.D.; and Nottingham, by Thomas Hawkesley, Esq., resident medical officer to the supply of water, on the Obstacles to Improvement in the Structure of Buildings, in the Cleansing of Streets and Houses, and in the Provision of Sewers and Seeders.

The Second Report of the Commissioners was presented to Parliament in February, 1845. It treats briefly of the Causes of Disease, and at considerable length of Remedial Measures. It is followed by a report on the means for rendering houses fit for human habitation, and by a recommendation for the regulation of the number of persons to be housed in various other towns, by R. A. Slaney, Esq.; a Report on the State of Bristol and other Towns, by Sir Henry T. de la Beche; a Report on the State of Large Towns in Lancashire, by Dr. Lyon Playfair; and a Supplement containing information on sewers, lodging-houses, and other matters connected with the interests of the Commissioners.

We have thus briefly stated the origin and progress of this important investigation into the sanitary condition of the population of Great Britain, chiefly indeed of the labouring and poorer inhabitants, but extending indirectly to all classes. Other agencies for improving the physical condition of the labouring classes are among the projects of the poor rate. Among these is the 'Health of Towns' Association,' of which the Committee includes noblemen, dignitaries of the church, members of Parliament, and other gentlemen. They have published a series of lectures on the Unhealthy Towns, its Causes and Remedies, delivered at Derby Hall, London, by William Augustus Guy, M.B., Physician to King's College Hospital; and 'Lecture on the Unhealthy Towns, its Causes and Remedies, delivered Dec. 10, 1845, at the Mechanics' Institute at Plymouth, by Vice-captain Ebrington, M.P.;' and a 'Report of the Committee to the Members of the Association, on Lord Lincoln's Bill.' (Lord Lincoln's Bill was introduced into Parliament at the close of the session of 1845.)

These important inquiries have proved by undeniable evidence, that the districts inhabited by the labouring classes, and often by tradesmen, in large towns, in many small towns, and in several parts of the country, are in a very noxious state, from want of drainage, want of cleanliness, imperfect ventilation, deficiency of water, and density of population; the consequences of which are great frequency of sickness, and excessive destruction of human life. Typhus fever, cholera, consumption, scrofula and other chronic complaints, mostly arising from causes which might have been prevented, are found to exist to an extent which it is painful to contemplate. The causes of sickness are generally most numerous and most intense in the crowded districts, and the mortality is found to be, with some qualifications, in proportion to the extent of popu-

lation. In the metropolis, for instance, the annual mortality is 3% per cent. in Whitechapel, but only 2% per cent. in St. George's, Hanover Square. In the district of Bethnal-Green, 57 houses of the population of the parish were closed in 1841; and in some cases there were 30 persons in a single house.

Of fifty towns which were visited by direction of the Commissioners, only eight were found to be in a tolerable state as to drainage and cleansing; and as to the supply of water the reports were still more unfavourable.

The annual average mortality in England is 2'207 per cent., or 1 in 45. In healthy districts it is 2'2 per cent., or 1 in 45. In the metropolis the deaths are 1 in 39; in Birmin-

gham and Leeds 1 in 37; in Sheffield, 1 in 33; in Bristol 1 in 32; in Manchester, 1 in 30; in Liverpool 1 in 29. In Brussels they have been found to be 1 in 24. The mortality was found to be greatest in the regions nearest the sea, in East Kent. By the return made to the Town Council of Liverpool in 1841, by their surveyors, it appears that there were then 2398 courts, which contained a population of 68,354 persons. In these courts 195 people were found to die within the year, or 240 per 1000 of the population. From the mortuary registers of the metropolis for 1824, the ages at death of the gentry, the tradesmen, and the working classes, who died at the age of 15 and upwards, Mr. Guy ascertained that the life expectation lived 50 years, and the working classes 48. In 1844 the deaths in the metropoli-

polis were 50,423. If the rate of mortality had been 1 in 50.
instead of 1 in 39, the deaths would have been only 40,145, thus giving a saving of 10,278 lives in one year. From a Report of the Registrar-General it appears that out of every million inhabitants in the metropolis, not more than 17,398 die every year in the large towns, and only 19,380 in the rural districts.

The large towns have already begun to make improvements. The improved drainage in twenty streets of Manchester is calculated to diminish the annual number of deaths by more than 20 in every 110; and similar results of structural improvement have followed in other instances.

The loss of life, and the pecuniary charges consequent upon it, are far greater than is generally supposed. The poor are not the only considerations to be attended to. Not only the sickness which precedes death, but the sickness which is caused, renders the sufferers incapable of following their usual occupations, and often prevents them from attending to the wants of the parish, and from public and private charity. It has been shown that pecuniary saving would result from sanitary improvements to such an amount as to justify the action of the legislature, if it were only from motives of public economy.

The power vested in the Court of Chancery by ancient usage is resorted to in a few towns for the abatement of minor nuisances. Mr. Coultart gives a detailed description of the various matters which have been taken cognizance of by the best judges at Assonnder-Lyne with beneficial effect. In most places, however, the exercise of these powers has fallen into desuetude, even where the courts still continue to be held.

2. The question of adoption in order to improve the sanitary condition of large towns and populous districts are comprised under the following heads:—

1. Drainage, including house and street drainage, the drainage of any place not covered with houses, yet influencing the health of the inhabitants.

2. The paving of streets, courts, and alleys.

3. Cleansing, comprising the removal of all refuse matter not carried off by drainage, and the removal of nuisances.

4. A sufficient supply of water for public purposes and domestic use.

5. The construction and ventilation of buildings in such a manner as to promote rather than injure the health of the inhabitants.

The Second Report of the Commissioners gives Thirty Recommendations to the legislature, each of which is preceded by the reasons on which the recommendation is founded. We can only afford space for a summary of some of these recommendations.

No. 1. Recommends that in all cases the local administrative body shall have the special charge and direction of all works required for sanitary purposes, but that the crown shall possess the general power of supervision.

No. 2 to 11 relate to Drainage; surveys and plans; definition of area for drainage by the crown; appointment of surveyors, investigators, etc.; authority of persons connected with drainage; management of the drainage of the entire area by one body; purchase of rights of mill-owners and others; construction of sewers, branch sewers, and house-drains; rating of lands; drainage of houses in separate apartments; when the rent is collected more frequently than once a quarter, or when the yearly rent is less than 10l.; provision of funds by the local administrative body, distribution of cost among the owners of the properties benefited, and charge of house-drains on owners of houses to which they belong; power to raise money, and provision for gradual liquidation of debt incurred.

No. 12 recommends that the Paving be under the same management as the drainage; but that it be performed by the local public officers.

No. 13, 14, and 15, relate to the Cleansing of all privies and privy closets, and of the streets and courts and due notice; removal of large collections of dung; and abatement of nuisances arising from noxious exhalations from factories.

No. 17 to 21 relate to the supply of Water, in sufficient quantities not only for the domestic wants of the inhabitants, but also for cleaning the streets, scouring the sewers and drains, and the extinction of fires; purchase of the interests of water-companies, and placing the management of the supply of water within the control of the persons who contract with the public; establishment of public baths and wash-houses for the poorer classes; and especially recommending that the supply of water in the towns be not only constant, but at as high a pressure as is circumstances, and that the water shall be of wholesome quality.

No. 22 to 26 are regulations for Buildings, including power to raise money for the purchase of property, for the purpose of opening thoroughfares, and widening streets, courts, and alleys; prohibition of use of cellars as dwellings, except when they are of certain dimensions and properly ventilated; provision for building all new houses with proper privies, and for a good system of ventilation in all edifices for public assembly and residence; and regulations for the construction and issue rules for regulation of lodging-houses for the reception of vagrants, trampers, and persons of similar wandering habits.

No. 27 and 28 recommend that power be given to the local administrative body to compel landlords to cleanse houses only reported to be in a noxious state from filthiness; and that power be given to the mayor, magistrates, and corporation to issue rules for the cleansing and maintenance of the pavement along the streets, and for the use of muck as a boundary. These regulations are of an important nature, and are to a great extent in accordance with the practice already established in London. The multiplicity of regulations gives them an advantage over them, and the improvement of the sanitary condition of the city has proceeded in a systematic manner.

No. 29 recommends the appointment of a medical officer in each town or district; and shall report periodically on the sanitary condition of such town or district.

No. 30 recommends the establishment of Public Walks, and that the local administrative body be empowered to raise the necessary funds for the management and care of the walks when established.

A large portion of the 'Report of the Committee on Lord Lincoln's Bill,' before mentioned, is occupied with showing that the supply of water, wherever practicable, should be constant, not only in the main pipes, but in the branch-pipes, thus doing away entirely with the use of water-huts; and demonstrating that in most cases such a constant supply is not only practicable but economical, and that it would contribute in the highest degree to the cleanliness of houses in crowded districts, and consequently to the health of the inhabitants.

PUBLIC POLICY. This expression sometimes occurs in the reports of public bodies, and seems to have a meaning somewhat less definite than the expression 'policy of the law' occurs. But of these expressions has a sufficient meaning. An example will explain how they are used. One man may agree with another for a certain valuable consideration to enter into a contract to carry on some trade, art, or business in London, and agree that he will not carry on the same within the realm of England. The object of the bargain is to secure to him who pays the money all benefit which may be derived from it. But he who has received the money may happen to break his contract by commencing the same trade, art, or business in a distant part of the realm as the 'Land's End or Newcastle-on-Tyne,' the original place of his business, or business being supposed to be in London. Now if an action were brought on such a contract, it could not be maintained, and the reason would be that the contract was against public policy, which would be explained to mean that the public ought not to be deprived of a man's services by such an unreasonable contract. Yet it would be said that if the contract were that the man who received the money should enter into trade, art, or business within a certain limited distance of London, the contract would be valid. This would imply that the public of a given district may be deprived of a man's services in another individual, not a reasonable grant, but that he may receive the full benefit of his contract. It would be a more consistent conclusion to declare the contract altogether invalid, if reasons of public policy, as they are called, are to be held to invalidate a contract, it is a question of the validity of the contract. But the administration of the contract is valid if it applies to a limited district, contains by implication a better reason for declaring the contract in its full extent to be invalid than reasons of public policy. The applied assumption is, that the person who pays the money is entitled to the full benefit of his contract and no more. If then it shall appear that he can sustain no real damage by the receiver of the money carrying on his trade, or art, or business at a remote place, that is a sufficient answer to his complaint. (Horner v. Graves, 7 Bing. 743.)

Still it may be said that there are contracts which ought to be declared void for reasons of public policy. If, for example, the correct expression of Lord Hardwicke, reasons of public utility (Earl of Chesterfield, &c., versus Sir Abraham Jannen, 2 Ver. 156), Lord Hardwicke observes, 'Particular persons in contracts shall not only transact particular fide in fact, but shall not transact molà fide in respect of other persons, who stand in such a relation to either as to be affected by the contract or the consequences of it; and as the rest of mankind besides the concerned, it is governed by public utility.' He gives as an instance 'premises contracted to be given for preferring or recommending to public office or employment; none of the parties are damaged, but the holders suffering the money may in these cases be or may be received thereby.' We may suppose a case in which the person recommended is a fit person, and no damage is caused by the bargain to give a premium.
But then it may be urged, as Lord Hardwicke would argue, that damage to the public service may be caused by such bills; and it may be said that it would be reasonable to presume that the possible damage to the public service is perhaps not the best ground on which to assume the invalidity of such bargains. If the person who has the appointment to a public service, is not appointed by a contract of employment, he is not a public servant. The same reason is equally applicable to any other person whose recommendation may help another to an office, for by the supposition the office is not a thing that can be the subject of bargain. Next, the term in the eye two disks of white paper about half an inch in diameter (or on a white ground, as a wall, place two disks of black paper), the disks being from three inches to two feet distant from a person to the front: then, standing with the right eye directly before the left hand disk, at a distance from it equal to five or five times the interval between the disks, and closing the left eye, look with the right at such object; it will be found that the right hand disk is invisible, in consequence of the light from it falling on the spot in the eye at which no image is formed. The left hand disk would disappear if the spectator, closing his right eye, should stand with his left eye directly before the right hand disk.

The experiment may be varied by standing with the right eye directly before the right hand object, then closing the left eye, and looking, without turning the head, obliquely at the left hand disk; the disks are small, the left disk yellow. It is found on moist sandy heaths in Great Britain. This species is the common Flees-bane; so called from its being disliked by vermin and used to drive away fleas. P. dysenterica has a creeping root, and is a herb more or less woolly or cottony, glabrous, and with a peculiar and aromatic smell. The stem rises 12 or 15 inches high: it is round, leathery, cottony, corymbose at the summit, with many bright yellow flower-heads, whose disk is of a darker hue than their numerous spreading rays. The leaves are acute, veiny, and wrinkled, or slightly toothed or serrated, from one to two inches long, sessile, clasping the stem, under the side cottony. The fruit is bristly and ovate, the pappus rough, the receptacle slightly cellular, unequalled toothed or scaly. Linnæus states, on the authority of General Keith, that this plant cured the Russian army of the dysentery. But Haller speaks contemptuously of the medicinal virtues of this plant, because he says it abounds in earthy matter. It is found in damp places in Great Britain.

(Burnett, Outlines of Botany; Lindley, Flora Medica; Lindley, by the author's death.)

PULMONARIA (so named from its being supposed efficacious in disorders of the lungs, or from the spots on the leaves resembling those on some diseased lungs), a genus of plants, includes the natural order of Pulmonaria. P. tuberulosa is a tuberous, a tubular, 6-calyx, a funnel-shaped corolla with a naked throat. The stem is attached to the tube filaments very short. The style is simple, the nectar smooth, attached by the top, the tube forming a common tube to the corolla, and terminal corymbose racemes of flowers.

P. officinalis, Langworth, has ovate leaves, roundish or cordate, the upper leaves oblong. The root is thick and black. The corollas are red before expansion and then purple. The whole plant is more or less hispid. It is found in the woods and thickets of England, and is native of Europe and the Caucasus. The leaves, which are the parts of the plant recommended in medicine, have no peculiar smell, but in their recent state manifest a slightly astringent and mucilaginous taste, which they are supposed to be demulcent and pectoral, and have been prescribed in consumption. All these plants contain nitre in considerable quantities, and when burnt this species yields one-seventh of its weight in ashes. In the root of Europe's eosin, a post and according to Ray in his time it was brought to table in Scotland.

P. angustfolia has all lanceolate leaves. It is difficult to distinguish from the former species, but is more pubescent, and is without hispid leaves. The root is purple, and there is a variety with white flowers. It is native of Russia. P. officinalis is a native of Europe and the Caucasus. All the species of Pulmonaria are pretty plants when in bloom, and are desirable for gardens on account of their early flowering. They are very easily cultivated, and will grow in any common garden soil: they are readily propagated by division. Most of the species grow well under the drip of trees and in moist situations.

(Deane, Dictionary of Botany; Dalington, Manual of British Botany; Burnett, Outlines of Botany.)

PUNCTUM CAECUM, in the eye, is the part of the surface of the retina which is immediately about the spot at which the light is focused by the medium of the eye. At this spot the retina has not sufficient delicacy of fibers to receive impressions from the rays of light which, coming from external objects and converging there, should form images of those objects: consequently the part contributes nothing to the perception of vision.

Its existence in each eye is proved by a well-known experiment, which was first made by Marriette:—on a dark ground, as a black sheet of paper or black cloth, place a vertical pin in the eye two disks of white paper about half an inch in diameter (or on a white ground, as a wall, place two disks of black paper), the disks being from three inches to two feet distant from a person to the front: then, standing with the right eye directly before the left hand disk, at a distance from it equal to five or five times the interval between the disks, and closing the left eye, look at the right at such object; it will be found that the right hand disk is invisible, in consequence of the light from it falling on the spot in the eye at which no image is formed. The left hand disk would disappear if the spectator, closing his right eye, should stand with his left eye directly before the right hand disk.

The experiment may be varied by standing with the right eye directly before the right hand object, then closing the left eye, and looking, without turning the head, obliquely at the left hand disk; the disks are small, the left disk yellow. It is found on moist sandy heaths in Great Britain. This species is the common Flees-bane; so called from its being disliked by vermin and used to drive away fleas. P. dysenterica has a creeping root, and is a herb more or less woolly or cottony, glabrous, and with a peculiar and aromatic smell. The stem rises 12 or 15 inches high: it is round, leathery, cottony, corymbose at the summit, with many bright yellow flower-heads, whose disk is of a darker hue than their numerous spreading rays. The leaves are acute, veiny, and wrinkled, or slightly toothed or serrated, from one to two inches long, sessile, clasping the stem, under the side cottony. The fruit is bristly and ovate, the pappus rough, the receptacle slightly cellular, unequalled toothed or scal y. Linnæus states, on the authority of General Keith, that this plant cured the Russian army of the dysentery. But Haller speaks contemptuously of the medicinal virtues of this plant, because he says it abounds in earthy matter. It is found in damp places in Great Britain.

(Burnett, Outlines of Botany; Lindley, Flora Medica; Lindley, by the author's death.)

PURCHASE, which is corrupted from the Latin word Persuasio, is defined by Littleton (r. 12) to be 'the possession of lands or tenements that a man may hold by a deed of agreement, unto which possession he cometh not by title of descent from any of his ancestors, or of his cousins (consanguineus), but by his own deed.' Purchase as thus defined has been comprehended in land by deed or agreement, and not by descent; but it is not a complete description of purchase, as now understood, for it omits the mode of acquisition by will or testament, which however, is the cause, when Land is purchased. It was species of purchase, as the power of devising lands did not then exist, except by the custom of particular places. Blackstone makes the following enumeration of the modes of purchase—Eschat-Ocupancy, Prescription, Forfeiture, and Alienation. As to eschaton, there is some difficulty in the classification, as the title appears to be partly by descent and partly by purchase; and alienation is here used in a larger sense than that which his term has in the Roman law, in which it does not comprehend acquisition by testament. Generally then, purchase is any mode of acquiring lands or tenements, except by Deed.
PYRANIS, a genus of Gasteropods, which includes two species, was found in the U.S. by an Austrian visitor near Holborn Bridge. (Brown, *Manch. Geol. Trans.*)

**PYCRETHRUM** (from wexl, fire, because of the hot taste of the root), a genus of Composite plants belonging to the tribe Asteraeae, contains the essence of the oenanthe, the receptacle flat or convex. The fruit angular and not winged. The pepus an elevated membranous border.

*P. Parthenium, Ferfewer,* has stalked pinnate leaves, with oval acuminate segments, a hard yellow-green, the leaflets incise to ovate decurrent and cut. The flower-heads are erect, about half an inch broad, with a convex yellow disk, and numerous short broad abruptly 2-ribbed white rays, often wanting, sometimes multiplied, and the disk being obliterated constituting a double flower. The whole plant is bitter and strong scented, reckoned tonic, stimulating, and anti-hysterical. It was once a popular remedy in ages. It is said that the oil is peculiarly disagreeable to bees, and that these insects may be easily kept at a distance by carrying a handful of the flower-heads. It is common in many parts of Europe and in England.

*P. acanthum* has sessile pinnate leaves, with ovate pointed segments. A branched stem, solitary heads, the involucral scales lanceolate obtuse; the fruit rugose with two round glandular dots on the external face just below the cypselae, and a border. It is found in fields and waste places in Great Britain.

*P. maritimum* has sessile doubly pinnate leaves, with fleshy segments, convex above, keeled beneath. The stem digitate, covered with tomentum. The flower-heads are oblong, about one inch broad, with 2 elongated glandular spots on the external face, just below the elevated lobed border. It is found on sea-shores in Great Britain.

Ithaca is the Pellessi of Spain, once much esteemed as a sialogogue, and resorted to for relief in toothache. Oake says that when the root of *pycrethrum* is chewed, it makes a sensible impression on the tip, which continues like the flame of a candle more powerful five or ten minutes after.

When extracted, the acrid oil contained in the root is said to be serviceable in cases of palsy, and when cutaneous action is required, as a liniment. Ainslie says it is administered in typhoid fever by the Indian practitioners. (Burnett, *Outlines of Botany; Linley, Flora Medicia; Balfington, Manual of British Botany.*)

**PYRINA,** a fossil genus of Echinodermata proposed by De Moulins for the Nucleolites depressus of the green-sand.

**PYRONE** is a term very recently applied to the electric fluid, derived from the Greek word word *pyros,* fire. The views of Mr. Lake, who first proposed it, a short time since, are novel, and certainly deserves consideration. He submits the change of name *because there appears to be a degree of indefiniteness in the terms electricity, electric fluid,* &c., and hoping that he has produced sufficient evidence in support of its materiality and existence, he states that he is ready to adopt the latter name.

**It might be an advantage if this or some similar name were adopted.** Electric might have been used, but as the fluid has no more connection with amber (**quarzo**) than many other substances possessing like properties, he has chosen to propose an entire change of name; and as it bears the greatest resemblance to fire, and seems to have a most intimate connection with that element, the word Pyrone is submitted.

He maintains, in the first place, that as electricity produces mechanical effects upon matter (for instance, reduces the strongest oak to splinters, and some substances into powder), that it is owing to water having been introduced by the action of fire. He states that when the latter is ignited, the moisture is driven off, and that the water is not the real agent. This is clearly shown in the following experiment.

Experiment 1. A size of iron wire (No. 26) was attached to the terminal wires of the battery. The positive was first immersed in the solution, and the circuit completed by the immersion of the negative wire. The latter burned with a beautiful reddish flame. This would seem to result from the following cause: hydrogen and pyrone being released at the negative pole on the decomposition of the water, and the oxygen of the acid having a greater affinity for these than for sulphur, the acid is decomposed, the negative element is oxidized, the hydrogen and pyrone released gas combining with the hydrogen and pyrone, combustion (ignition) takes place. When the experiment is reversed, and the negative wire first brought into the solution, the circuit being completed by the positive wire, the latter became red-hot to the extent of an inch and a half under the solution. This resulted from the accumulation, as it is called, at the poles of the unconnected pikes, rendering the pyrogenic current more powerful at first, and increasing the temperature during its continuation. No flame appeared at the positive pole, there being no hydrogen present, all that obtained having escaped at the negative electrode.

**Experiment 2.** A platinum plate, an inch long by half an inch wide, being attached to the negative wire, and a small iron wire at the positive, the platinum being first immersed in the solution, and the circuit completed by the positive wire, it became red-hot an inch and a half under the solution, as in the last experiment, and from the same cause; but when it was only brought into contact with the solution it fused, which was prevented when it was immersed in a little nitric acid.

**Experiment 3.** When the iron wire was placed at the negative end of the battery and the platinum at the positive, the platinum being first put into the solution and the circuit completed by the positive wire, it became red-hot an inch and a half under the solution, as in the last experiment, and from the same cause; but when it was only brought into contact with the solution it fused, which was prevented when it was immersed in a little nitric acid.

**Experiment 4.** A fine copper wire was attached to the positive terminal, and a platinum wire to the negative. The platinum being as usual first immersed, and the circuit completed by the insertion of the copper wire, the latter was heated an inch under the water. The cause of there being no flame is the same as in the former experiments, for the copper wire being at the negative electrode, no hydrogen was present to produce it. But when the experiment was reversed, and the copper wire introduced at the negative pole and the platinum at the positive, the latter being first immersed and the circuit completed by the former, the copper or negative wire burned with a bluish flame, oxygen and hydrogen being formed, as before, but at the opposite pole.

**Experiment 5.** A slip of zinc was used instead of copper wire, and with the same result; for when placed at the positive termination, and the platinum at the negative, and the latter immersed in the solution, no flame was produced at the negative pole, but the hydrogen at the positive, the latter first immersed, the zinc at the negative burned with an intense purple flame, hydrogen being present, as before, at the other pole.

**Experiment 6.** With platinum at the positive and sulphur at the negative, the platinum being first
immersed, the antimony or negative electrode fused and inflamed, depositing on the glass and surface of the solution an orange-coloured powder resembling Kermes' mineral. When the same process was tried on potassium, the negative and the latter first immersed in the solution, white fumes were given off by the sulphuret, but it was not ignited, for, as in the preceding experiments, there was not any hydrogen at the negative, and some others; for when any of these are united as an amalgam with mercury, and exhibited in this state to ammonia, an amalgam of mercury and the bases of ammonia is formed, and the fixed alkalies or earths are reproduced, the first amalgam having absorbed the pyrogen and oxygen of the second.

In explaining the experiments of Messrs. Schönbein and Gann with ozone, Mr. Lake deduces that zinc, nitrogen, and hydrogen are not simple bodies. He draws this conclusion as regards the metals from the different colours of the flames in the experiments of Messrs. Pollack and others on the ignition of metals in acid solutions, and, in respect to zinc, the additional singularity of the smell produced by it when used as an electrode in obtaining an oxide. As to the opinion concerning the gases, he arrives at it from ozone (which he considers to be a compound of oxygen and the electric fluid) being obtained from them. [Ozone, P. C. S.]

One other point remains to be noticed, namely, the connection of the electric fluid with the action. Concerning this our author says,—"Pyrogen enters into the composition of carbonic acid, which may be generated by the passage of a current of the former from charcoal (that is, carbon) points. By this means the oxygen of the atmosphere unites with the carbon, which has the greatest possible affinity for it when pyrogen is present in motion." Again, "Carbonic acid can be dissolved by the abstraction of pyrogen from it, by exhibiting to it gum arabic and other substances which have a specific action on it. When carbonate of ammonia is employed in producing an amalgam of the bases of ammonia and mercury, there is a most decided decomposition of this acid and formation of carbonaceous matters.

"Pyrogen also enters into the composition of nitric acid, which is produced on passing sparks or discharges of it through atmospheric air. . . . By analysis, pyrogen may be obtained from nitric acid by using a solution of the latter in the experiments on the ignition of metals in acid solutions. [Ozone, P. C. S.] In a similar manner it may be procured from nitric, phosporific, and many other acids."

These views of this subject may explain many phenomena going on around us, the causes of which have hitherto been inexplicable. Thus, in one of his papers Mr. Lake says that the development of carbonic acid by plants results from the electric fluid, which is in a constant state of circulation, unitive with the carbon of the plants and oxygen of the air. He might have gone farther, and shown, upon his own theory, that plants not only make use of the fluid in this manner, but that they actually produce it from the water with which they are supplied, as is proved by Pouillet's experiments with insulated corn-plants.

The subject being now, we will not enter into further details; but the above is the substance of what has appeared concerning it.

PYROLA [WINTER-GREEK, P. C.]

PYXIDICULA, an obscure genus of fossil Infracrusta.

(Eberghen.)

INDEX TO THE LETTER P.
QUADRATURE. Not thinking of this Supplement, we inserted in the article TRACTION, P. C., the extension given to the approximate arithmetical quadrature by Mr. Rutherford (Phil. Trans., 1841). With this reference, we take the opportunity of saying that we have re-examined the numbers, and find them correctly printed.

Strange as it may seem, this problem of the quadrature of the circle still engages attention: and persons are found to believe that they have attained even the arithmetical quadrature. It has been stated in foreign newspapers within these few years that the British government does offer, and always has offered, a large reward for the solution of this problem. This, we need hardly say, is a complete mistake: the government never at any time offered one farthing for the quadrature of the circle. The only problem for the solution of which any reward was at any time offered, was the practical mode of finding longitude: and even this offer is now retracted; rewards having been, in fact, received by several persons. Should this article fall into the hands of any, at home or abroad, who are working at any mathematical or astronomical difficulty under the impression that our government is pledged to remunerate them in case of success, they may rest assured that their information is incorrect, and that they will find it to be so on inquiry.

QUICKSANDS are those masses of loose or moving sand which are formed on many sea-coasts and generally at the mouths of rivers: those of the Nile and Senegal are among the most remarkable for these accumulations. The sands are generally conveyed by the rivers from the interior of the country, and being at first arrested by the waters of the ocean, they become, by the action of the winds and tides, moveable bars, which are very dangerous to shipping. The loose sands on the coasts are, when dry, driven by winds over the land, which they then cover often to a considerable depth, overlying the fertile ground and occasionally entombing whole villages: the coasts of Cornwall in England and of Jutland in Denmark are particularly subject to these encroachments; and it is stated that, in the latter country, there are vast beds of sand so loose as to be incapable of supporting the weight of a man. In Greenland there is a chain of ice-hills between two promontories of moving sand, which is driven by the winds far out to sea.

The sand of Bagshut Heath, which rests on London clay, is in many places, at a few feet below the surface, saturated with water so as to constitute a perfect quicksand and, on the borders of Oman, in Arabia, there was discovered by Baron von Wrede a remarkable quicksand, which is said to be more than 60 feet deep.

RADIATA. [Rated as RADIATED ANIMALS, P. C.]

RADIOL. [From radiolus, little ray, in allusion to the rayed capsules], a genus of plants belonging to the natural order Gramineae, has a stiv of 4 sepals connected below, deeply trifid. There are 4 petals, 4 stamens, 4 capsules, with 8 cells and 8 valves.

R. is the only species of this genus. It is the R. bienes of some botanists, and is a British plant. The stem is from one to two feet high, repeatedly forked, with solitary flowers in the axils as well as at the extremities of the branches. The flowers are small and white; the capsule light brown and slightly depressed; the sepals deeply and acutely 3-cleft, connected below into a tube. The seeds of this very small plant should be sown in a moist situation where the ray seeds would be allowed to scatter themselves.

(Baillie, Manual of British Botany; Don, Gardener's Dictionary.)

RAIA, a genus of cariologic fishes, established by Linnæus, and since subdivided by ichthyologists. The rays differ from the sharks in being horizontally flattened so that their bodies with their broad and flabby pectoral fins resemble large expanded disks. The eyes and spiracles are placed above the mouth, nostrils and bronchial orifices below.

The dorsal fin springs from the tail. The common skate and the ray are familiar examples.

The following are the principal sub-genera into which R. is divided:

Toretipo. Rays with short and rather thick tails, and having the disk of their bodies nearly circular. Their teeth are small and sharp. The torpedos are remarkable for the electrical apparatus with which they are provided; it is seated in the part between the pectorals, head, and branchia. Fishes of this genus are rare in the British seas, but common on the coasts of southern Europe.

R. bartletti is a large species. The head is slender and bears two small dorsal fins towards the extremity, with sometimes an imperfect caudal fin. The disk of the body is rhomboidal; the mouth is armed with slender slightly-set teeth arranged in quincunial order.

Trigonus. The single species of Trigonus has a slender tail armed with a sharp serrated spine by which the fish can inflict severe wounds; hence its popular name. The head is enveloped in the pectorals, and the teeth are slender and arranged as in Raja proper.

Myliobatis. Tail very long, armed and bearing a small dorsal fin; head projecting from between the pectorals, which are separated by the breast of the pectoral fins, giving the creature a very extraordinary and incomplete or mutilated aspect.

The whip-ray belongs to this sub-genus.

Cephalopetera. Tail also armed, and bearing a small dorsal, but the head is curiously truncated, and is placed between two hollows, the breach of the dorsal pectoral fins, giving the creature a very extraordinary and incomplete or mutilated aspect.

The teeth are small and very slender.

RAILWAYS. [Transit, Railways, P. C. S.]

RAIMBACH. ABRAHAM, one of the most distinguished English line engravers, was born in London in 1776; his father was a Swiss by birth, but he settled in England at the early age of twelve, and never afterwards quitted it; his mother was the daughter of an English farmer in Warwickshire.

When an infant, Raimbach escaped from one of those rare but awful accidents which occasionally happen through the negligence of nurses; he fell from the arms of his nurse by an open second-floor window; but his life was saved, partly by the inflection of his long clothes, and partly by his fall being broken by some leads below. The girl from whose arms he fell was seized with such a panic that she rushed out of the house, and was never heard of by any of the Raimbachs afterwards.

Raimbach was educated in Archbishop Tennison's library-school, where he was the fellow-pupil of the late Charles Matthews; he, however, showed an early determination to excel in the arts, and his father apprenticed him in 1789 to J. Hall, the engraver; and J. Heath had both declined to take him. The first work engraved by the young apprentice was the explanatory key to Copley's Death of Chatham in the National Gallery, where the print also is now hanging, framed and glazed, beneath the picture. After his term of apprenticeship was over he entered as a student in the Royal Academy, anxious to qualify himself in every way for his art; he at the same time did what work he could for the book-sellers; but at this period he seems to have been little cultured in earning as much as thirty shillings a week. His first patron was a bookseller of the name of Stockdale. But, by his general attention and assiduity, he was enabled to unite the profession of a miniature painter with that of engraver, and he prospered in a short period so well in both, that he was under the necessity of giving one of them up, and confining himself to the other. According to his own account, he was influenced not a little in his choice by the uniform difficulties he met with in satisfying his sitter with his miniatures. All had opinions of their own about their looks, which it was necessary to attend to; he therefore gave up portrait painting, as he found engraving a much more independent art.

In 1802, through some prints he executed for Smirke and Forster's illustrated edition of the Arabian Nights, he was in such circumstances as enabled him to take advantage of the temporary peace, and he paid a visit to Paris to view the great galaxy of works of art which the victories of Napoleon had collected together in the Louvre. He has himself given a long account of this tour in his autobiography, published by his son. In 1805 he married and established himself in a house of his own in Warren-Street, Fitzroy-Square, in which he lived twenty-five years, and during which time he executed, the house was given to him by his father on his marriage, and his father died in the same year; in 1807 he lost his mother also. In this year he made the acquaintance of Wilkie, and soon became that painter's intimate friend. In 1812 he became Wilkie's engraver, supplying Burnet, who had already engraved some of Wilkie's pictures in an admirable manner. The chief reason of Wilkie's breaking with Smirke was that what was considered the most valuable interest of his in the prints—one-third of the profits. Burnet would not allow more than this, and Wilkie left him for Raimbach, with whom, however, he was contented with the same arrangements; and, indeed, he himself afterwards voluntarily reduced his share to one-fourth of the profits. The first fruit of this partnership was the celebrated print of the 'Village Politicians.' This print however, owing, it appears, to the indifference of print-sellers to anything out of the ordinary way of business, at first went off slowly; but eventually the sale was large and steady, and a proof of which there were 274, has sometimes been sold at auctions for fourteen or even fifteen pounds. Another print was afterwards published in 1816; after which Wilkie and Raimbach made a tour together in the Netherlands. The rest appeared in the following order: 'The Cat Finger,' 'The Errand-Boy,' 'The Blindman's Buff,' 'The London-Scot,' 'The Beggar,' 'Beadle,' and, in 1836, 'The Spanish Mother and Child.' The last prints, compared with the 'The Village Politicians' and 'The Rent-Day,' were very unsuccessful speculations, and Raimbach thus accounts for the fact in his autobiography:

For the long term of more than twenty years the prints from Wilkie's pictures had enjoyed an almost unprecedented popularity; and it can scarcely be held as a matter of reproach to the public if, after so long a period of favour in one direction, the desire of some sort of change of object should be entertained. The great talents of Edwin Landseer had been already well appreciated, when his picture of the Monks of Bolton Abbey appeared, and placed his reputation on a still higher elevation. Seconded by Cousin's admirable mezzotinto from it, there followed a rush in the track thus so suspiciously commenced, and the new lights (as in Aladdin's lamp) were preferred to the old. Raimbach never employed an assistant, but executed the whole of the plate himself. 'The Rent-Day' cost him two years and a half of incessant labour. His prints are very masterly works, and possess every quality but colour. He died at Wallsend in 1827, 28, in very easy circumstances. His autobiography was published by his son in the same year, under the following title:

Memoirs and Recollections of the late Abraham Raimbach; including a Memoir of his Son, David Wilkie Raimbach.

RAE, JEAN-PHILIPPE, a very celebrated musician, equally distinguished by his compositions and by his
numerous writings on the science, was born at Dijon, in 1638. It may be presumed that he inherited a taste for music, for his father was so passionately fond of the art that after he had been five years in the profession, and obtained the organist’s chair in the Sainte-Croix of the above-named city. He taught his children to play from notes before they could read from letters, and the success they made as organists, so far as relates to musical education, is manifested in the instance of his eldest son, the subject of the present notice, who when only seven years of age was thought an able performer on the harpsichord. He pursued the usual studies of Latin and Greek, which he acquired without reluctance and readily; but an invincible desire, or instinct, as his biographer calls it, led him to music, to which he at length wholly devoted himself. At eighteen he was organist at the church of St. Etienne-du-Mont in Paris. In order to continue the art to which his future life was to be dedicated, but proceeded no farther than Milan, where he became acquainted with a professor with whom he returned to France, and together they visited several of the principal cities, exercising their talents at each with pecuniary views. Soon, however, tired of a wandering life, that allowed him no opportunity for indulging in those speculative inquiries to which he was prone, he went to Paris, and there added largely to his stock of information. Afterwards he became organist of the cathedral of Clermont, in Auvergne, and continued long in that city, in which he wrote *L’Oiseau de l’Harmonie*, but not finding the readers for printing a large quantity of his compositions, he proceeded to the capital of France, where in 1722 he published his great work, and finally fixed himself. He was elected professor of the college of Saint Croix de la Bretorniere, and employed his spare time in copying ancient theoretical treatises, in composing his harpsichord lessons, and in teaching. He did not distinguish himself in that line in which he was desirous to excel till the year 1730, when, at fifty years of age, he produced the opera of *Hippolyte et Aricie*, the drama by the Abbé Pellegrin. The success of this provoked much professional envy, if not national discord, and a feud was raised among the admirers of Lully [LOUL, P.C.] and Rameau, similar to that which in after times was carried to greater excess by the Gluckists and Piccinnists. [GLUCK, P.C.; PICCI, P.C.] The Prince de Conti asked Campra, the celebrated Maître de Musique of Notre-Dame, what he thought of the new work? He replied, ‘There is enough of music in it to make six operas.’ Till the production of *Hippolyte*, Voltaire alone had discovered Rameau’s genius for composition. He previously gave him his tragedy of ‘Samson’ to set, and discerned the beauty of its music; but its performance was prohibited under the pretext that it prostituted a sacred subject. Of the many operas by Rameau, his ‘Castor et Pollux,’ published in 1733, and his ‘Médée’ in 1737, is the best: it was represented one hundred times. There are parts of it that must always excite the admiration of true connoisseurs. A chorus in this, of Spartans, ‘Qui tout germesse,’ has been set to music by many modern masters. Even M. Ginguéni, who estimates his countryman at a low rate, admits the merit of this composition. His ‘Dardanus,’ his ‘Zoroaster,’ and other pieces, were equally successful. From 1724 to 1769, he was Maître de Musique of the King’s Palace, and besides harpsichord and other compositions; together with many theoretical and controversial works. His merit, long contested by envious rivals, was at length generally acknowledged. The king created him for the office of cabinet composer. Afterwards he granted him letters of nobility, and named him ‘Chevalier de Saint-Michel.’ The Academy of Dijon had previously received him among their members, and the French Senate, in recognition of his fame, exonerated him from the impurity, from the tax called ‘La Taille.’ He died in 1764, leaving a son and a daughter, and was interred with every mark of respect and distinction.

Rameau’s style of writing is not remarkable for perspicacity. This was felt and acknowledged by his most zealous partizan, D’Alember, with sufficient justice. It is ‘superficial and prate- 

tique, suivant les Principes de M. Rameau,’ has endeavoured
to clear the work from the obscurity in which it undeniably
is involved; but the great French geometer has only par-
tially succeeded. He has been assisted in this task by the
early edition of the ‘Encyclopedia Britannica’ adopted
D’Alembert’s work. In later editions the article has been
omitted, and a much better one substituted. (Biographia Universelle; De Laborde, tome iii.; Burney, vol. iv.)

RAMENGUI, BARTOLOMEO, called IL BAGNACA-

VALLO, from the place of his birth, Bagacavallo, on the road

from Romagna to Bologna, is, in his capacity as a pupil of Raphael, as one of his principal assistants in the Vatican; and after the death of his great master he carried the principles of his style to Bologna, and assisted to enlarge the reputation of that school. Raphael was his model and test of excellence, and he did not attempt to look beyond him, presuming that little was to be acquired by ordinary abilities from nature compared with what the works of Raphael afforded for imitation. Though possessing less vigour than Giulio Romano or Perino del Vaga, Bagacavallo acquired more of the peculiar grace of Raphael’s style, especially in his infants, and his works were much studied by the greatest masters of the fifteenth and sixteenth centuries. His works by Bagacavallo in San Michele in Bocco, San Martino, Santa Maria Maggiore, and Santi Agostino agli Sco- pettini, in Bologna. He died at Bologna in 1542, according to an incorrect document of his biographer Thevet, but it was Bagacavallo, who assisted Vasari in Rome, and Primitracio at Fontainebella, was the son of Bartolommeo Ramenghi.

(Brunfeldi, Le Vite di’ più insigni Pittori e Scultori, Venice, 1624; this report was based on a MS. in MS., but it has been recently (1846) published for the first time at Ferrara by Domenico Taddei, after lying in MS. for nearly a century. Lanzi, Storia dell’Arte, &c.)

RAMMOHUN ROY. Rajah, born about 1774, in the district of Burdwan, in Bengali, Hindostan. His paternal ancestors were Brahmins of a high order, and were devoted to the religious duties of their race, till about the beginning of the seventeenth century, when they gave up spiritual exercises for worldly pursuits. His maternal ancestors, also of high Brahminical rank, and priests by profession as well as by birth, uniformly adhered to a life of religious observances. Rammohun Roy was taught Persian under his father’s roof, was sent to Patna to be instructed in Arabic, and afterwards, at the request of his maternal relations, went to Benares, in order to be initiated into the Vedas. He was initiated into the Vedas in 1787, is it the best: it was represented one hundred times. There are parts of it that must always excite the admiration of true connoisseurs. A chorus in this, of Spartans, ‘Qui tout germesse,’ has been set to music by many modern masters. Even M. Ginguéni, who estimates his countryman at a low rate, admits the merit of this composition. His ‘Dardanus,’ his ‘Zoroaster,’ and other pieces, were equally successful. From 1724 to 1769, he was Maître de Musique of the King’s Palace, and besides harpsichord and other compositions; together with many theoretical and controversial works. His merit, long contested by envious rivals, was at length generally acknowledged. The king created him for the office of cabinet composer. Afterwards he granted him letters of nobility, and named him ‘Chevalier de Saint-Michel.’ The Academy of Dijon had previously received him among their members, and the French Senate, in recognition of his fame, exonerated him from the impurity, from the tax called ‘La Taille.’ He died in 1764, leaving a son and a daughter, and was interred with every mark of respect and distinction.

Rammohun Roy was a Brahmin by birth, and was trained by his father in the doctrines and observances of his sect; but his opinions seem to have become heretical at an early age. He became a disciple of Hylas Kim, a Dr. Stump of the Serampore mission, and visited South India in 1790. In this he was inspired by a scripture calling in question the validity of the idolatrous system of the Hindos. This, together with my known sentiments on that subject, having produced a coolness between me and my immediate hind, I removed, in my travels, and from county to county, through different countries, chiefly within, but some beyond, the bounds of Hindostan. When I had reached the age of twenty my father recalled me, and restored me to his favour.’ Afterwards he says, ‘My continued controversies with the Brahmins on the subject of their idolatry and superstition, and my interference with their custom of burning widows, and other pernicous practices, revived and increased their animosity against me, and they engaged my father to expel me from his family, and go into India. My father was again obliged to withdraw his countenance openly, though his limited pecuniary support was still continued to me.’ His father died in 1803, and he then published various books and pamphlets against the Brahmins, in the native and foreign languages. ‘The ground which I took in all my controversies was, not that of opposition to Brahminism, but to a perversion of it; and I endeavoured to show that the whole system is built against the interests of their ancestors, and to the principles of the ancient books and authorities which they profess to revere and obey.’ In order to deprive him of caste, the Brahmins commenced a persecution against him, which, after many years of litigation, was decided in his favour.

Of the body of Hindu theology comprised in the Vedas [VEDA, P.C.]; there is an abstract called the ‘Vedant, or the Resolution of the Veda,’ written in Sanscritic
Rammohun Roy translated it into Bengalee and Hindustanee; and afterwards published it in an abridgment in the 'Circaut.' This publication was entitled "The Precepts of Jesus the Guide to Peace and Happiness." In this section he omit the miracles and doctrinal parts, and confines himself to the simple religious and moral precepts. In 1830 he was engaged by the King of Delhi to make a representation of grievances to the British government, for which purpose the King conferred on him the title of Raaj, and appointed him ambassador to the British court. He arrived in London in April, 1831. The British ministers recognised his embassy and treated him with every mark of respect and hospitality. He returned to India on September 27, 1833. He was buried in a shrunken bar of Stapleton Grove, without a pall over the coffin and in silence. The Christian observers were carefully avoided at his own request, lest it should be made an occasion against him by the Brahman caste and, by causing him to lose caste, deprive his children of their inheritance. His funeral was attended by his youngest son born to him, who had come to England with him. Two other sons survived him in India.

Rammohun Roy was acquainted more or less with ten languages—Sanskrit, Arabic, Persian, Hindustanee, Bengalee, English, French, Hebrew, Latin, and Greek. Sanskrit and Arabic he knew critically, and as a scholar; Persian, Hindustanee, Bengalee, and English, he spoke and wrote fluently. Of the other languages his knowledge was less perfect. In person he was tall and somewhat unwieldy; his features were handsome, his complexion dark, and the general expression of his face was very pleasing. He associated a good deal with the Unitarians in this country, and frequently attended their meetings. He added to the helms of the Unitarians in Christ, and seems to have considered the acceptance of the doctrines of Christ to be quite consistent with a belief in the Brahmanical religion as it is in the ancient Sanscrit authorities. He was the author of "On the origins of the Labour, Opinions, and Character of Rammohun Roy," by Last Carpenter, LL.D.

Rampart, probably from Riga, an embargo, from which is derived the Italian word "Riparo," and the French word "Rempart," is, in modern fortification, a mass of earth often nearly 80 feet thick, surrounding a town or a military position, or constituting the face of an outwork; and its use is to protect the interior of the town from work or work or against any sudden enterprise of the enemy, as well as to give the defenders a superiority of elevation with respect to the works of the besiegers.

The ramparts of ancient fortresses were walls of stone or brick, frequently from 80 to 100 feet high and 30 feet broad, including the galleries made in them; round or angular towers were formed at intervals along the wall; and, by means of the galleries, the defenders could pass within the thickness of the wall from each tower to the next. The rampart was surmounted by a parapet seven feet high and two feet thick, which was provided with casks and water and had a transverse parapet. It was in order that the exterior foot of the high wall might be defended, machicolations were formed at the top, particularly over the entrances. [Bartros, P. C.] A great mass of earth was raised against the wall nearly as high as the top, places where elevated ground or the enemy's works on the exterior allowed access to the top of the wall to be gained in force; and on this mass the cohorts were drawn up in order of battle. (Vitruvius, lib. i., cap. 1.)

The modern rampart is surmounted by a parapet of earth, on the interior side of which, towards the town, is a nearly level space, varying in breadth from 35 to 40 feet, called the terreplein of the rampart; on this terreplein the garrison was placed: and in the rear of the guns there is room for the movements of the defenders and the conveyance of the ammunition. The exterior and interior sides of the rampart are formed with slopes in making angles of not more than forty-five degrees with the horizon: or they are retained by revetments, or walls of brick or stone, nearly up right, the exterior face of the rampart constituting the escarp of the ditch in front. The rampart is generally placed at a greater distance from the walls than the escarp, and was lengthened, in parts making salient or re-entering angles with one another; and these parts constitute the faces and flanks of the bastions, and the curtains which connect the latter together. Not more than 80 feet are allowed for the breadth of the terrepleins of the ramparts of outworks, measured from the foot of the parapets, in order that the enemy may not be able to form batteries for artillery upon these terrepleins. The terrepleins of all ramparts should have a small slope down, towards the interior, in order that the rain-water may not lodge on them, and that the defenders near the interior edge of the rampart may be effectually covered by the parapet. The interior slope of the terreplein in the front is generally covered with turf. A rampart whose exterior side is of earth, or without a revetment of brick or stone, might be easily ascended by an enemy at the time of an attack, and might be penetrated in that case, would be planted in it for the purpose of impeding the progress of the enemy, might be easily destroyed by artillery, so that the place would be liable to be carried by a sudden assault.

The relief, or height, of a rampart is regulated by the occasional necessity of employing a fire of artillery from the rampart, and, at the same time, a fire of musketry made over the glacis by men posted in the covered way beyond the ditch in front of the rampart: for this purpose a line of fire from the rampart should pass three or four feet above the crest of the glacis in its front, in order that the wind of the shot may not injure the defenders. The relief of a rampart with its parapet may, therefore, be thus determined:—On a drawing representing a vertical section of the works let a line be drawn from the foot of the glacis, through a point taken at 3 or 4 feet above the crest of that work, and let it be produced till it cuts the interior slope of the parapet on the rampart: this intersection will give a point in the axis of a gun placed on the rampart, or a point a few inches above the sole of the embrasure, that is, about 33 feet above the terreplein of the parapart; and, because the artillery are to be protected by the parapet, if 74 feet be the height of the embrasures of the glacis, 51 feet will be the height of the glacis, and 23 feet will be the height of the ground, the sum will be the required height of the crest of the parapet.

Rampur, a town of Hindustan, in the district of Bareilly, province of Oudh, India, on the boundary of the laws of the east bank of the Cisira river, in 28° 48' N. lat., and 79° E. long., 106 miles E. by N. from Delhi, direct distance. The town, at the time of the death of Fynola Khan, a Rohilla chief to whom it had been secured by the peace of Lalding in 1774, was four miles in circumference, and the centre of a flourishing district, but has since been greatly reduced. The district was granted to the nawab of Oudh on the termination of the Rohilla war, and the town was ceded to the British in 1801, by whom it was transferred to the nawab of Rampur, together with a small territory.

Rampur is chiefly remarkable for the curious fortification by which it is surrounded, a high and thick kind of bamboo faced on the outside by a prickly underwood of cactus and babool. The entrances are by narrow passages, defended by strong wooden barriers. It is said to be extremely effectual in resistance against irregular troops, since neither cavalry nor infantry can be brought to act against an enemy whom they cannot see, and who is flying from them among the close shrubs, and can be covered only by the almost impenetrable cover on the outside. (Hamilton's East India Gazetteer; Heber's Narrative of a Journey through the Upper Provinces of India in 1834 and 1835.)

Ramsay, Andrew Michael, generally known as the Chevalier Ramsey, was born at Ayr, in Scotland, the year 1868. He was educated at Edinburgh, where
chiefly devoted himself to the study of mathematics and theology; the distinction he obtained as a scholar procured for him the appointment of tutor to the son of the Earl of Wemys, at the University of St. Andrew's. Having entered into a religious controversy, the fruits of which were an increase of his doubts and even an inclination to general scepticism on the great doctrines of the Christian religion. In this state of mind he determined on having recourse to Fénélon, who was at that time residing in his diocese of Cambrai. Ramsay was but twenty years of age when he formed the acquaintance of the Archbishop of Cambrai, but his mind had already been sufficiently trained by study and meditation to enable him to appreciate the talents and to recognize the virtues of that eminent divine. Towards him Fénélon exercised his instructive talent as a moral teacher, and in short time made him a convert to the Roman faith. He soon became the disciple of Fénélon, not only in religious matters, but also in his literary taste and opinions. His writings were formed on the style and after the manner of his great master, whose phrases and precepts were very satisfactorily acknowledged. Ramsay readily acquired so perfect a knowledge of the French language as to become an excellent writer. Some of his earlier productions were the means of obtaining for him an appointment as tutor to the Duke of Château Thierry and afterwards to the Prince of Turenne; he was also created a knight of the order of St. Lazarus. His reputation induced the Pretender, in 1724, to invite him to Rome, and to employ him in the education of his son. He remained there however only a year in that city, and left it in disgust with the petty intrigues which he found to form the principal occupation of the miniature court of the son of the exiled king. The next year he revisited Scotland, where he remained a considerable time, which he employed in literary labours. On leaving England, he obtained, through the influence of Dr. King, the degree of doctor of civil law in the University of Leyden, and he was also admitted a member of the Royal Society of London. After his return to France he was appointed intendant to the house of Turenne, who afterwards became Duke of Bouillon; he held this situation till his death, which took place at St. Germain-en-Laye in the year 1743.

The writings of the Chevalier Ramsay are more remarkable for the purity of their style and the perfect knowledge which they manifest of the French language, than for their depth or originality of thought. As a theologian he was visionary in the extreme, and his orthodoxy, even according to the niceties of the church he had professed, was often considered as a surprise. It is fortunate for his religious reputation that he did not live to publish some philosophical works which he was preparing, such as his answer to Spinoza, and a treatise on Human Understanding, ' in which he says Spence, 'there were several notions that would have made him be looked upon as a heretic in our church, as well as in his own.' (Spence's Anecdotes, p. 84.) The work of the same author, on the ' History of Cyrus,' is in imitation of the Telemachus of Fénélon, but, according to Voltaire, a very feeble one. The character of Zerina gave considerable offence to the Princess of Conti, one of the most learned ladies of the age, who imagined that she was portrayed in it. There is an excellent translation of that work, by Hooke, though said to have been accomplished in the short space of twenty days [Hooke, Nathaniel, F. C.]; it is far a long time afterwards mistaken for an attack on the belief respecting it being that Ramsay had written the Voyages of Cyrus in English as well as in French. The best edition of the French is that of 'Paris et Londres,' 1727, 2 vols. 8vo. The work, however, for which posterity is most indebted to him is that entitled 'L'Histoire de la Vie de François de Saligan de la Motte Turenne.' Hague, 1728; published also in London the same year. His great intimacy with the Prince has been accounted for by his personal acquaintance with the facts of his private life, and it contains a valuable record of his opinions. His other published writings are 1°, 'Discours sur la Méthode,' originally prefixed by the Prince of Condé in 1728, 8vo. 'Théorie Philosophique sur le Gouvernement Civil.' London, 1721; it was afterwards reprinted under the title 'Essai de Politique.' 2°. 'Histoire de Turenne.' Paris, 1725, 3 vols. 8vo. and 4 vols. 12mo. With some affectation in the style and a redundancy of reflection this history possesses much merit from the precision of its facts and the lively portraiture of its characters. 4°. 'Le Psychomètre, ou Réflexions sur les différents Caractères de l'Esprit, par un Mylord Anglais.' 6°. A posthumous work published in 1760, entitled 'Philosophical Principles of Natural and Revealed Religion explained and unfolded in a Geometrical Order.' (Dictionnaire Historique, vol. 4, Amsterdam, 1788; Dictionnaire Historique Critique, Paris, 1799; Speck's Dictionaries of Books and Men, London, 1800. The details of his conversion to the Roman Church will be found in the life of Fénélon by le Fère Quereubeuf, appended to his edition of his works, Paris, 1721.)

Ramsay, Allan, an eminent portrait painter in his time, and the son of Allan Ramsay the poet, was born in 1718, in Edinburgh, the birth-place of his father also; the ceremony was performed by Churchill, in his satire of the 'Prophecy of Fame':—

'Then came the Ramsays, men of worthy note,
Of whom the world could tell, as the other gods.'

'\"Ramsay\", says Edwards, \"may be called self-taught; but he studied a short time in Italy with Solimena, and F. Fernand, called Imperiali. After practising a short time in Edinburgh, he settled in London, where he was introduced by Lord Bute to George III. when Prince of Wales. He painted two portraits of the Prince, which were engraved, one by Ryland, and the other by Wootlett. At the death of his master Mr. Shepherd, King of Prussia engaged him to paint the king; he retained the place until his death, when he was succeeded by Sir Joshua Reynolds. He died at Dover in 1764, on his return from a fourth visit to Rome; he had painted the portrait of Pope Clement XIII. Edwards says that Ramsay was not an excellent portrait painter, was superior to the generality of the painters of his time; he was Walpole's contemporary, and is noticed in somewhat flattering terms by that universal critic, considering with whom he is coupled: he says, 'Ramsay and Reynolds and Ramsay have wanted subjects, not genius.' Edwards says that Ramsay was not devoted to his art; he allowed literature to divide much of his time with it. He was also a judge of French, and Italian; and, in his latter days, like the elder Cato, acquired some knowledge of Greek. He was the author of some political papers. He was twice married; his last wife was a daughter of Sir David Lindsay. His son and daughter survived him; the son became a general in the British army, the daughter was married to Sir Archibald Campbell.'

(Edwards, Anecdotes of Painters; Cunningham, Lives of the British Painters, etc.)

Randin (named after Isaac Rand, M.D., once a demonstrator of botany at the Chelsea botanic gardens), a genus of plants of the Gentian family, is of a brownish color, and is noted for its annual flowering. R. dunatorum, Bush-Randia, is a thorny branching small shrub or tree, with oval leaves, rather blunt, cuneate at the base and smooth. The flowers are very sweet-scented, sessile, solitary, yellow, nodding, not in clusters, like the villosa. The fruit is smooth, yellow, resembling a small crab-apple, firm and fleshy. The seeds are oval, numerous, and lying in mucus. The fruit when bruised and thrown on the floor, is covered with a mucus, like the Coccus Indicus, which is not, however, known in the East Indies, where this plant grows. In the form of powder it is powerful a emetic. An infusion of the bark of the root is employed to nauseate in bowel complaints. R. wilkinson, Bog-Randia, has almost terminal opposite thorns, tetragonal branches, oblong leaves somewhat cuneate, glabrous; the flowers solitary, sessile, almost terminal. It is a native of the Lower Llobregat, the grooved root is much more like the villosa than the villosa. The fruit is large, white, and fragrant, and in two or threes at the top of the branchlets. The berry is about the size of a pullet's egg, blue-green, and peckled. The seeds are fattish, nearly globular, in the pulp. The flowers of this species render it deserving of a conspicuous place in the hothouse.

The uncommon appearance of this plant is also in its favour. There are 88 species of Randia, none of which, however, are applied to medicinal purposes. They are good for the Asiatic flowers. The soil best suited for them is a mixture of loam, peat, and sand. The flower stave thrive best in a moist heat; they do not flourish readily if kept up in a dry hot heat under a glass. They are very showy, usually bearing large white fragrant flowers, and are worth cultivating in every collection of semi-tropical plants.
RAN COUNCLE, a noble family of Modena, which became illustrious in the middle ages, not only for the part which it took in the political and military vicissitudes of Italy, but more particularly for the patronage which it gave to learning and to the arts. Count Nicolò Rancone, who lived in the latter part of the fifteenth and first part of the sixteenth century, had two daughters, whom he caused to be instructed with great care, and all of whom became distinguished for their love of science and learning. The eldest, Laura, was the preceptor to several of them, has left an interesting memorial of the care bestowed on their education in his Dialogues entitled  'Antonio Maria Visdomini de Oculo et Sybillis.' One of his grandsons, Count Cesare Rancone, was a distinguished general in the Venetian service, and afterwards in the service of King Francis I. Filofo, in his book 'De Optima Hominum Felicitate,' which he addressed to Count Guido, enumerates the acts he had performed in his military career, and praises him likewise for the liberal encouragement which he afforded to the learned. Bernardo Tasso, father of the great poet, was for a long time secretary to Count Guido. Guido died at Venice in 1537. His brother, Cardinal Enrico Rancone, who died young during the pagille of Rome in 1527, is likewise extolled for his love of learning by Guglielmo Giraldi, and also by Vida in his second book 'De Arte Poetica.' Mr. Curtis says that the cardinal used to take his meals with his dog, and to peruse, while dining, a large book; and to look for his second husband Cesare Fregoso, a well-known Genoese emigrant in the service of Francis I., who was murdered in 1541 by the emissaries of the Marquis of Vasto, Governor of Modena and Pesaro, Countess Camilla, who was betrothed at the age of twelve to Bandello, the celebrated novelist, who wrote many of his tales for her entertainment. Ginella Rancone, sister of Costanza, married first a nobleman of the Correggio family, and in consequence of her nobility and intelligence, was well known in Ferrara. The character of her sister, Balbo, has been praised by Scaliger for her intellectual accomplishments. Her nephew, Count Fulvio Rancone, a pupil of Carlo Sigonio, was employed by Alfonso II. of Este in a diplomatic capacity, and his sister Claudia fixed her residence at Rome, where she enjoyed considerable interest at the papal court, and was even consulted on matters of state. The love of learning and the patronage of the family and house appears to have been hereditary in the family of Rancone. The Marquis Gherardo Rancone founded in 1783 a Scientific Academy in his palace at Modena, which awarded prizes for physiological and other studies and discoveries.

(Litta, Famiglia celebri Italiani; Tiraboschi, Storia della Letteratura Italiana; Memorie intorno alla Vita del Marchese Gherardo Rancone, Modena, 1818.)

RANUNCULUS (from ranus, a frog, because many of the species inhabit humid places frequented by that reptile), a genus of plants, the type of the natural order Ranunculaceae. It has 5 sepals, occasionally 10, with a nectariferous excretory sac at the base of the receptacle. The calyx is generally tubular, the achenia ovate, somewhat compressed, mucronate, arranged on globose or cylindrical receptacles. The species are mostly acrid, and if applied when fresh to the skin will produce blisters: this quality is destroyed by drying or by heat.

R. aquatilis, Water-Crowfoot, has a floating stem and submerged leaves divided into numerous capillary segments spreading on all sides. The floating leaves are remiform, from 3- to 6-parted, the lobes wedge-shaped, toothed at the top, the petals obovate, larger than the calyx, the flowers white or yellow. It is native throughout Europe, Western Asia, North Africa, and also in America and England, in pools and stagnant waters. It is the Baragew tatravov of Dioscorides, 2, 206. Sometimes it produces very large flowers, and grows 3-4 feet high and it has a curious and valuable variety in the floating and immersed leaves adds greatly to its beauty. Dr. Pulteney contradicts the assertion of its deleterious qualities, and says that it is not merely harmless but nutritive to cattle, and tells us that on the borders of the Avon the cottagers support their cows and horses almost wholly on this plant. Hogs are also fed upon this plant, and appear to thrive on it, so that it seems we cannot class this species with others of the same genus as having poisonous qualities.

R. flammula, Flame-Crowfoot, is a smooth plant with a rooting decumbent stem, branched, leafy and hollow, sometimes hairy. It is common in all parts of the country, with half-sheathing stalks, alternate, usually ovate, lanceolate, but varying much in breadth, often serrated. The flowers are terminal, opposite the leaves, and of a bright yellow colour. The leaves are vestigial. Dr. Withering recommends the distilled water as an instantaneous remedy in cases of poison.

Lightfoot says the bruised leaves are used to raise blisters in the Isle of Skye and the Highlands of Scotland. It is native of Europe, Asia, North America, and Great Britain.

R. glacialis has stalked radical leaves, palmated and trifid, the lobes blunt, the flowers generally one-flowered; the calyx very hairy, the carpels compressed and sharp-edged; the petals white. It is native of the higher Alps of Europe and the Rocky Mountains of North America, the mountains of Dauphiny call this 'Carville' or 'Carrilline,' and employ an infusion of it in hot water as a powerful sudorific in colds and rheumatism.

R. acris, Buttercup, has a fibrous root, the stem about two feet high, erect, round, hollow, leafy, clothed with close-pressed hairs, branched above and many flowers. The radical leaves are on long upright footstalks, in 3 or 5 deep lobes, the stem-leaves are nearly sessile, with fewer and narrower segments, the uppermost most smaller in 2 linear entire lobes, or sometimes simple and linear. The flowers are of a bright yellow, on round even stalks covered with close hairs and not furrowed. The calyx is hairy, spreading, and deciduous; the carpels smooth, lenticular, with a slightly curved point. This species is extremely acrid and dangerous. Lightfoot says that bruising up and applying it to some little distance has produced inflammation in the hand. Cattle in general will not eat it, but sometimes when they have been turned hungry into a field they have fed upon it, and for Ciba has been used as a cure for corns.

According to Linnæus sheep and goats eat it, but cows, horses, and swine refuse it. When made into hay however, its noxious qualities are lost. It is commonly called buttercup, under which name it is found in all the herbals, and is owing to these plants. A double variety of this species is cultivated in gardens under the name of 'Bachelor's Button.'

R. sceleratus, Celandine-Crowfoot, has a fibrous root, the radical leaves with 3 stalked trifid and cut leaflets, furrowed peduncles and reflexed calyx, the heads of the fruit oblong, the carpels minute and with a single seed. The flowers are very small and pale yellow, numerous, on solitary stalks, either terminal, axillary, or opposite the leaves. The bruised leaves raise blisters on the skin, which are not soon healed, and are said to be used by impostors to cause ulcers on their bodies, and thus excite compassion. It is one of the most virulent poisons of our native plants. The distilled water of this species is highly acrimonious, and when cold deposits crystals which are scarcely soluble, and a great effusion of tears,

The delterious qualities are, however, dispelled in decoction, and accordingly the shepherds of Wallachia boil it and eat it.

R. Thora has an exceedingly acrid and poisonous root, and is native of the Alps of East France. It is formerly used by the Swiss hunters to poison their darts; wounds so produced speedily become fatal.

R. flaxius, Filowetor, has a root with fasciculated tubers, coriaceous stalks and leafy, or corymbose, or corymbose, or corymbous, or corymbous-flowered stem, usually three sepals, and smooth blunt carpels. The flowers are golden yellow, and it is native throughout the whole of Europe in meadows, bushy places, and about hedges, and it is fruitful in Britain. The young leaves of this plant, according to Linnæus, are used as greens in Sweden. A notion that the root is efficacious in the cure of piles it gives its common English name. We usually find the flower closed from five to nine in the evening, and in wet weather. It is the χελιδόνιον of Theophrastus, Hist. Plant. 7, 14, and the χελιδόνιον μερος of Dioscorides, 2, 212, and of Pliny, Hist. Nat. 24, 195.

R. arvenis, Corn Crowfoot, has a fibrous root, the radical leaves 3-leafed, dentate, the stem-leaves once or twice ternate, with linear lanceolate segments, the calyx erect-patent, the carpels marginated, beaked, and spinous; the flowers are pale yellow. It is native throughout Europe, in North America and Great Britain. It is very acrid and dangerous to cattle, though they are said to eat it greedily.

M. Brunton, who has given a particular account of its qualities, relates that three ounces of the juice killed a dog in four minutes. Several sheep were killed by eating this herb at Turpin, which first led to an investigation of the matter.

R. bulbosum, one of the commonest and most extreme acrid, and raises blisters and produces extensive inflammation of the skin. Gilibert states that it vesicles with less pain than cantharides and without affecting the urinary passages.

R. ranunculus, common Garden Ranunculus, has a terminal or
ritenate leaves, the segments toothed or deeply trifid, the stem erect, simple, or branched at the base, the calyx spreading, afterwards reflexed, the spires of the carpels cylindrical, the style shorter than the calyx. The flowers of the latter species are yellow or blue. The flowers of this variety are generally formed double, and have all colours except blue. It is called the Persian Ranunculus. 2. R. a. languidus, with a simple stem, ternate leaves, the segments leafless or with a small point, the flowers being yellow, orange, or yellow. This is called the Turkey Ranunculus. 3. R. a. hirundinarius, with a somewhat branched stem, and multifid leaves with linear acute lobes. It is a native of the island of Cyprus, and has white or yellow or purple flowers.

The Garden Ranunculus is a florist's plant, and has been cultivated with great care. The garden varieties of this species are very numerous, as no two plants produce flowers precisely alike. Madder, who wrote on these plants, had a collection of 800 varieties, all with proper names. In judging of a Ranunculus the following qualities are desirable:—The flowers should be of a hemispherical form, at least two inches in diameter, consisting of numerous petals, gradually diminishing in size to the centre, lying over each other, so as neither to be too close nor too much separated, but having more of a perpendicular than a horizontal direction, in order to display the effect. The flowers are with entire rounded edges, their colours dark, clear, rich, or brilliant, either of one colour or variously diversified on an ash, white, or yellow ground. The flower buds are often spotted or mottled in an elegant manner. (Georg. Del.) In cultivation this plant prefers a rich loamy soil, which should be well manured, and it is customary when forming beds for it to place a layer of well-rotted cow-dung seven or eight inches below the surface. They are usually propagated by dividing the roots, which may either be planted in November or March. The former is the best time, but the roots should then be mulched. In order to obtain varieties, seeds should be obtained from the single or semidouble plants, and planted in August. The following year, when their leaves drop off, the roots should be taken up and dried in the same manner as the old roots, and planted with them in November.

The R. languidus Linnæus is the barbatus Linnæus (Schoenoprasum of Dioscorides, loc. cit. The R. mucronatus, Linnæus is the barbatus Linnæus of Dioscorides, loc. cit. (Don, Gardener's Dictionary; Lindley, Flora Medicæ; Fränz, Synopsis Flora Classica Plantarum; Burnett, Outlines of Botany.)

RAPHIOSAURUS, a genus of fossil Reptiles from the lower Cretaceous of the Cretaceous system (Owen.)

RAPE. [Rape, P. C.; Law, Criminal, P. C. S.]

RASK, RAMUS CHRISTIAN, one of the most distinguished linguists of modern times, was born on the 2nd of May 1787, at Nyborg in the province of Fyen, or Funen, in the kingdom of Denmark. His parents were poor people, but the boy's talents and inclinations procured him friends who afforded him the means of procuring his education at the university of Copenhagen. He afterwards spent some time in Iceland, and also made journeys to Sweden, Finland, and Russia for the purpose of increasing his knowledge of languages, for which he had a very extraordinary talent. In 1808 he obtained a situation connected with the university library at Copenhagen, and he availed himself of the opportunity by making himself acquainted with the most ancient documents of Danish history and literature. His knowledge of languages led him to devote himself to comparative philology, to search after the connecting links and trace them to their common origin; and in order to complete this branch of study, he undertook in 1817, with the support of the Danish government, a journey to Russia, whence he proceeded in 1819 to Persia. He made some stay at Teheran, Persepolis, and Shiras, and in 1820 went to India, from whence he returned in 1822 to his native country. In this expedition he had purchased for the Copenhagen library 118 ancient and rare oriental manuscripts, among those in the Pali language were the most valuable. Rask was invited to the university of Edinburgh, but as he declined the offer, he was appointed professor of the history of literature in the university of Copenhagen. The king had promised him his support, if Rask remained in Denmark, but for some time he neglected them, and devoted his time to an analysis of the Danish language. In 1827, however, he returned to his oriental pursuits, and wrote on Egyptian and Hebrew chronology, and on the age and authenticity of the Zend a Vesta. In the meantime he had commenced the publication of the Danish Academy, the Society of literature, and of the society for the investigation of northern antiquities, and he took an active part in the management and editorship of the journals of these societies. At the same time he performed important work on the Sami, the Iceland, and the Norwegian languages, and wrote two dictionaries of the Scandinavian, including also the eastern languages, but his edition of Lokman's Fables, Copenhagen, 1832, shows that his knowledge of Arabic was very deficient; and it may be said in general that, as far as the oriental languages are concerned, he had more skill in general comparisons and investigations of their grammatical structure than an exact knowledge of any particular language. His works show that there was scarcely a language worth studying of which he had not some knowledge: and all the civilized languages of Europe were almost as familiar to him as his own mother-tongue, and his knowledge of the northern languages is univalved. He died at Copenhagen on the 14th of November, 1832, and his numerous MSS. relating to philology were given up by his relatives to the king's library at Copenhagen.

The principal works of Rask are, 1. An Introduction to the study of the Icelandic and ancient Northern Languages, Copenhagen, 1811; 2. An Anglo-Saxon Grammar, Stock-holm, 1817; one of his best works, has been translated into German and Danish. 3. An Introduction to the Investigation concerning the Origin of the ancient Northern or Icelandic Language, Copenhagen, 1814; 4. An edition of Björn Haldorson's Icelandic Ili- cary, Copenhagen, 1814; 5. A Spanish Grammar, Copen- hagen, 1894; 6. A Friian Grammar, Copenhagen, 1851; 7. An attempt to reduce the Orthography of the Danish Language to Principles, Copenhagen, 1826, is a strange work in which Rask attempted to introduce a complete reform in Danish orthography. He did not succeed in his attempt, but the work is full of the most extraordinary linguistic learning; 8. On the age and authenticity of the Zend a Vesta, Copenhagen, 1826, was translated into German by F. H. von der Hagen, Berlin, 1826; 9. A small Grammar and Vocabulary of the Acra Language. In the last year of his life he finished a very complete Grammar of the Language of Lapland. A number of essays on linguistic subjects appeared in various journals, and in Vater's 'Verzeichnisarbeiten,' there is one on 'Die Tharkische Sprachclasse,' which is of great importance and interest. Comparative philology is greatly indebted to Rask, for he was the first who pointed out the connexion between the ancient northern languages of the one hand, and of the Lithuanian, Slavonic, Greek, and Latin on the other hand. (Zeitungen, third series, No. xxxi.) RATIO, COMPOSITION OF the 'Five' or 'Ten' words which are found in the statements in Ratio, P. C., p. 4; and will be worth while to add considerable development. The idea implied in composition of ratio is very imperfectly treated in Euclid; and yet upon the composition of the ancient mind, as we will show, he has been invincible over the difficulties of inconceivable which appeared in the fifth book gives reality or imaginary.

In every matter connected with elementary geometry, confusion may and often does arise from mixing together criticisms of two different kinds; on Euclid as a writer, and on the subject as a matter of thought. To avoid such confusion we begin with the consideration of what we find in Euclid—not in Simon's Euclid, nor Playfair's Euclid—but in Euclid of Alexandria.

There is nothing on ratio compounded (epagogen) of ratios in the fifth book; the word translated composition (epagoge) refers to such a process as the formation of the ratio of A+B to B from that of A to B. But the definitions of, duplicate, triplicate, &c. ratio are laid down; which, as we shall see, are particular cases of the compounded ratio of A to B: and so on.

In one proposition, and in one only, is the phrase composition of ratios used: in the 23rd of the sixth book, where it is stated, 'Euclid has compounded of the sides.' There is no definition at least, it
press it, how-much-fold is used instead of how-many-fold, that much may suggest the idea of part of a time (commissurable or not) where many would only suggest that of an integer. We cannot much admire this refinement; nor does it give any help: for the introduction of the idea of incommensurability numerical names is ceased, as so to be fit for arithmetical multiplication, would vitiate Euclid's whole system of proportion.

But the oldest testimony, both to the existence of the definition, and the meaning of the disputed word, is Eutocius in his commentary on book ii. prop. 5 (of Torelli, 4 of preceding editors). He here cites, expressly from the elements, the definition as given; and adds, as the explanation of the word, 'as in arithmetic,' that it is the number which, by multiplication, turns the consequent into the antecedent. This number, he says, gives name to the ratio, and he cites Nicomachus and Hero as understanding it in the same way. But, he goes on to say, the word is more properly taken when this number is an integer.

Leaving now out of view what Euclid really did write, we shall proceed to consider the subject of composition of ratios, so as to supply what, on any account, was certainly omitted from the editors of the sixth book. Peyrau has omitted it in the Paris edition, because, in his celebrated Vatican manuscript, it is not in the text, but has been added at the side. The Berlin editor admits it in parentheses; and, with great justice, sets this of the most important propositions of the treatise of Euclid from the ordinary mode of weighing the evidence of manuscripts, and there is little doubt this definition must appear as a part of the original text of the Elements. The conclusion by the internal evidence of the passage, and its keeping with the rest of the book, and there is as little doubt that it would be rejected. The meaning of the passage is, apparently, that the ratio compounded of the ratios 7 to 4 and 6 to 11, the ratio compounded of those ratios is to be the ratio of 7×6×4×11; or possibly, expressing the above ratios as those of 7 4 to 1, and 6 11 to 1, the compound ratio is that of 5 7 11 to 1.

In the early translations from the Arabic, the definition is omitted, and reference is made in demonstrating vii. 23 to a note inserted among the definitions of the fifth book, which is very insufficient. But the phrase there is that the ratio of f to g is produced from those of f to g and g to h: and to the definitions of the seventh book several are added, one of which is, that in a series of numbers the ratio of the first to the last is produced from the successive ratios of each to the one following.

In many manuscripts there is a scholium preceding the sixth book, which August, the Berlin editor, though not admitting it into Euclid, thinks must be of high antiquity; in which, however, he agrees with him. It is to be found in the Beadle edition, and in the notes to the Berlin. This scholium, while it gives confirmation to the preceding view (which hardly wants it), takes the same side on the meaning of the word ratio as we have done. [RATIO, P. C.] And we find that Wallis was the person who suggested to Gregory quantitas instead of quantitas as the translation. See his discussion of this point at length in his English Algebra (1684), ch. 19 and 20; revised in his Latin Algebra (Works, vol. ii. ch. 19, 20), and again at p. 665 of the same volume, where there is a defence of this definition against Henry Saville, who (Præfacium, in Excursus) had considered it a great defect. To the text of Euclid we have only further to say, that this consent of Saville, Wallis, and Gregory, as to the genuineness of the definition in question, is of great weight. But with respect to the matter of the definition we agree entirely with Saville. The word ratio needs definition quite as much as the term composition of ratios itself. This definition, it will be observed, either restricts the composition to ratios which are of commensurable magnitudes, or implies and assumes the multiplicity of two interminable decimal fractions. An old scholiast on Euclid (cited from Dassypodium by Melbonius and Wallis) is of opinion that ratio is understood rather than the more technical word ratio; and, if truth be understood in a wider sense, so as to include fractional and incommensurable ratios. That is, as Wallis ex-
being integer numbers: it being known that every commensurable ratio is expressible by the ratio of two integer numbers. Take any magnitude \( P \), and alter it in the ratio of \( m \) to \( n \); it becomes \( n \)-nths of \( P \). Alter this in the ratio of \( a \) to \( b \); it becomes \( a \)-a-bths of \( P \) which would also be obtained by altering \( P \) in the ratio of \( a \times m \) to \( b \times n \). Hence composition of numerical ratios is performed by multiplication of the antecedent and consequent, and of the consequents for a consequence. The process that is merely equivalent to that of the multiplication of fractions.

If \( \frac{a}{b} \) and \( \frac{c}{d} \) were called the quantuplicate (quantitruncatur) of the ratios, then the quinquuplicate of the compound ratio is the product of the quinquuplicate of the components, as in the definition (be it Euclid's or no) which is found in the manuscripts of the elements.

Duplicate ratio (\( \frac{a \times b}{c \times d} \)) has been defined by Euclid in the manner hereinbefore given. But it is in fact the ratio arising from the composition of two equal ratios. Suppose we want to compound the ratio of \( P \) to \( Q \) with the ratio of \( P \) to \( Q \). Take a magnitude to begin with, which may as well be \( P \) itself: alter it in the ratio of \( P \) to \( Q \); it then becomes \( Q \). Alter \( Q \) into \( R \) in the ratio of \( P \) to \( Q \); that is, let \( R \) be a third proportional to \( P \) and \( Q \). Then \( P \) is changed into \( R \) at these two steps. Each involves an alteration in the ratio of \( P \) to \( Q \); hence Euclid's duplicate ratio is the compounded ratio of two equal ratios; and, similarly, triplicate ratio (\( \frac{a \times b \times c}{c \times d \times e} \)) is that compounded of three equal ratios.

The subduplicate, subtriplicate, sesquiplicate, &c. ratios, which later geometers used, completed that language of multiple and submultiple applied to operations of powers, which roots which finally suggested the idea of logarithms. (See also Additions to Ratios, P. C.)

The propositions requisite for the establishment of the direct use of compound ratio are contained in the fifth book. But in the inverse use there is a manifest hiatus in the converse part of vi. 22. It is supplied by a lemma added at the end of the proposition; which is found in almost all the manuscripts (even in the Vatican manuscript, where it is more correctly). This is a pretty sure sign that Euclid did not give the lemma; for he never refers to anything which is to come after what he has in hand. Robert Simson omits this lemma, and so leaves the proposition undemonstrated. What is wanted is the following:—It is impossible that the same ratio should be the duplicate ratio of two different ratios; or, if \( A \) be to \( B \) in the duplicate ratio of \( A \) to \( X \), and also in the duplicate ratio of \( A \) to \( Y \), then \( X \) and \( Y \) must be equal. If possible, let them be unequal; say that \( X \) is the greater:

\[
\frac{A \times X}{B} \quad \frac{A \times Y}{B}
\]

Then because \( X \) is greater than \( Y \), the ratio of \( A \) to \( X \) is less than that of \( A \) to \( Y \). But the ratio of \( A \) to \( X \) is that of \( X \) to \( B \); and the ratio of \( A \) to \( Y \) is that of \( Y \) to \( B \); therefore the ratio of \( X \) to \( B \) is greater than that of \( Y \) to \( B \); therefore \( X \) is greater than \( Y \); but it is also greater, which is absurd. Consequently \( X \) and \( Y \) cannot be unequal, &c. By a continuation of this process it may easily be established that a given ratio can only be the triplicate of one ratio, only the quadruplicate of one, and so on.

It is unnecessary to say anything on the decomposition of ratios. Just as it becomes in arithmetic, after a while, that every multiplication is a division and every division a multiplication, it is much clearer from the beginning, in this subject, that every composition is a decomposition, and every decomposition a composition. Suppose \( \frac{a}{b} \) to \( \frac{c}{d} \) is the ratio compounded of \( A \) to \( B \), and \( C \) to \( D \), and we wish to return back again to the ratio of \( A \) to \( B \). We must compound the ratio of \( P \), with that of \( D \) to \( C \); for it is easily made obvious that the ratios of \( C \) to \( D \) and \( D \) to \( C \) compounded give the ratio of a magnitude to itself, the ratio of equality, the use of which effects no alteration.

It is now easy to see that all the operations of algebra which spring from multiplication inclusive, must be represented in geometry by operations of composition, &c. Robert Simson, who, as we have seen, has left a demonstration of the sixth book absolutely unfinished, though "Theon or some other" had provided it, for it which seemed to be what was wanting, has thought it necessary to add some very complicated propositions on compound ratio at the end of the fifth book. If they were intended as illustrations of the great difficulty of rendering the compound propositions of algebra into geometrical language (and what else could have been meant it is hard to imagine) the geometrical equivalents should have been introduced. Take the proportion \( K \), for instance, which it may safely be added to no beginner ever fathomed. The foregoing is an illustrative case of it. If

\[
\frac{a \times c \times e}{b \times d} = \frac{x}{y} = \frac{\alpha}{\beta} = k
\]

And \( a \times c \times e \) \( b \times d \) = \( k \times l \)

Then \( e \times g \)

\[
\frac{a \times c \times e \times k \times m}{b \times d \times f \times h} = o
\]

REAU R I M U R I A Z E, A natural order of plants belonging to the Exogenous class. It has a 5-parted calyx, surrounded externally by imbricated bracts; 5 petals, hypogynous, un-echinoid, sometimes having a pair of membranous plates planted upon their middle; definite or indefinite hypogynous, monadelphous, or polyadelphous stamens, with or without a hypogynous disk; the anthers ovate, turned inwards, and bursting longitudinally; 2-4-6 carpels, partially separate from each other, surrounding a central placenta which passes into the base of each; 2 or 4 ascending anatropous ovules, with filiform or subulate styles; a carpulifer with 5 to 6 valves and as many styles; the two styles, upon two stigmas; plants erect; short slender erect flowers, with a straight embryo surrounded by a small quantity of mealy albumen, and the albumen not very much. The species of this order are small shrubs, with fleshly scale-like leaves, and have no stipules, and are overspread by resinous glandular hairs.

This little order consists of three genera, Resunaria, Hololachna, and Eichwaldia, which were formerly referred to Tamaricaceae; they have, however, but little affinity with that order. Their true affinities seem to be with Hypericaceae, near to which Lindley has placed them. The species are generally natives of the coast of the Mediterranean, and of salt plains in the milder parts of northern Asia.

The genus Resunaria was named by Fiseau in honour of René Antoine Percheron de Resun. (REAU R I M U R I A Z E, P. C.) It has a 5-parted involucrated calyx; 5 petals, permanent, furnished at the base on each side with a ciliated appendage; numerous pendulous stamens; 5-6 stigmas; a 5-valved capsule, with valves easily separating from the septa, and shaggy seeds.

R. termiculata has subulate semitericate imbricated leaves, crowded on the branches. It is a native of Sicily, Bombay, and Egypt. This plant resembles Salacia fruticosa. It is used at Alexandria as a remedy for the itch, being bruised and applied externally, and a decoction taken internally.

R. hypogynus has lanceolate flat rather remote leaves. It is a native of Syria and Persia. These leaves are elegant little shrubs of easy culture, which thrive well in a mixture of sandy loam and peat; and young cuttings will grow freely in almost any soil.

Hololachna (from holo, entire, and \( \lambda \chi \nu \nu \), wool, or thick hair) has a 4-5 parted calyx; 4-5 petals; 8-10 hypogynous monadelphous stamens inserted into an hypogynous gynoecium; 4-5 short subulate styles; the receptacle at first globular, 2-4 valved, 2-4 seeded; the seeds few, large, surface shaggy. The only species is \( H. \) Somparia, found by Ehrenberg in the Soomparian garden of Siberia. In cultivation this plant requires to be watered with care, and allowed to dry out. All the plants of this order abound in saline matter in their tissues.

(Lindley, Vegetable Kingdom; Don, Gardener's Dictionary; Lindley, Flora Medica.)

REBEATE is the old English word for Discount [P.C.]. The discounting of a sum of money, or the paying something less for it before it becomes due, is now always done by striking off a certain per cent. Thus, if a sum be due a year hence, say 100L, discounting at five per cent. means paying 95L in lieu of 100L a year hence.

There are one or two old difficulties connected with discount, which we intend, so far as we understand them, to notice under other heads. The first is that of the equation of payments. Were it not for the difficulty, and its principle, this would not be worth notice. It was at one time the custom of the works on arithmetic which preceded this, to pay sums of money due at different times, at what time the total amount is to be paid at once, in such manner that the receiver may gain, by the sums which are prepaid, what he loses by those which are overdue.
To take a simple case, say it is understood that money makes five per cent. simple interest, that 100l. is due in three years, and 400l. in seven years. The rule as it was given leads, as the reader knows, to the payment of the whole 400l. in six years; by which the interest on 300l. paid a year before its time balances on that 100l. paid three years after its time. It is not fair; for not interest, but discount, should be allowed for the sum paid before it is due. That is, the 400l. paid at the intermediate time should yield 100l. due + interest on it since it was due + a sum which put out to interest will make the 300l. at the end of the seven years. The rule for this case gives a result 5.9615574 years, instead of six years; which will be found to satisfy the conditions.

In truth, however, it depends entirely upon what the notion of fairness is, whether one rule is better than the other, or whether either will do. And it must be remembered that simple interest is a fiction in real business. A creditor cannot demand more than simple interest by law; but it does not therefore follow that because certain money is paid under the name of interest, the receiver will let it lie barren in a bag. But what we say is this: keep to the fiction on which both rules are constructed, let all interest-money remain barren, and the two rules will come to the same thing in the end. And it is not fair to construct rules on the supposition of simple interest, and then to complain of the inaccuracy of these rules to represent the results of real business. Remaining by simple interest, let us see how the receiver will stand at the end of the seven years, upon the different suppositions.

1. If no equation of payments be made, he will have 100l. + four years' interest + 300l. just received, 420l. in all, with which he is to go on making interest on 400l. only.

2. If he receive by the first rule 400l. at the end of six years, he will at the end of the seventh year have 420l., or which 400l. is to go on at interest as before.

3. If he receive by the second rule he will have at the end of the seventh year (100l. + 2961l. interest) which he received + 1308l. years' interest which he makes on the 100l. (the other part not making interest) + the sum which will in 1308l. years yield 300l. (285.19l. + ...) + the interest on this. That is, 420l. altogether, of which 290l. is interest only: for the last-mentioned item, though gained in the manner of interest, is discount intended to make up a principal.

Or, if any one will not admit this last distinction, then the approved rule puts the receiver in a worse position than the old rule.

The fact is, that if equation of payments were ever made, it ought to be supposed that all money, principal and interest, becomes productive money to the receiver from the moment it is received: or compound interest should be supposed. This puts the parties into a state of equity at all times, both during the longest term of debt and after. To show this suppose that A is due at the end of a years and B at the end of b years, interest being r per pound. To satisfy this debt by a sum A+ B paid at x years from this time, the equation to determine x is

$$A + B = A(1+r)^{-x} + B(1+r)^{-x}$$

and the receiver of the equated sum, x years after its receipt, or x+m years from the present time, will have $$(A+B)$$

$$(1+r)^{-x}$$

or

$$A(1+r)^{-x} + B(1+r)^{-x} = x$$

And this is precisely what he would have had from the payments themselves. And the accumulations or present value of the equalized sum at all times equal to the accumulations or present values of the payments.

There is another remarkable case of the same kind, in which discount at simple interest is compared with notions derived from compound interest, and where it is seen to be false which is, upon its own hypothesis, perfectly true. The value of an inerrainable annuity, calculated at simple interest, comes out infinitely great: or no sum is large enough to pay t.

Now it is easy to see how such a sum of 1l. a year, at 5 per cent. for ever. And this may even be called simple interest, for at the end of a year the interest of the 20l. is paid away, and the original principal only remains: so that there is no interest upon interest. But the truth is, that in the construction of all rules at simple interest, the money is arbitrarily divided into two parts, productive and unproductive, and a rule which expressly requires payment to be made from time to time out of the productive part, may produce very different results from another in which the unproductive part is paid away first. Now take the case of an annuity for three years, of 1l. money making r per pound. The ordinary rule gives

$$(1+r)^{-1} + (1+2r)^{-1} + (1+3r)^{-1}$$

At the end of a year, this becomes

$$1 + r + r^2 + r^3$$

The first term is partly principal, partly interest: and of annuity has become due. But the manner in which the rule was framed does not allow us to pay away the r(1+2r) and r(1+3r), which are never to make interest again, in part of the first year's annuity, but requires that the 1, part of which will make interest, should all be so paid.

And, when the productive money is broken in upon before the unproductive is all gone, it is perfectly true that no sum is large enough to pay a perpetual annuity: and, if this be done, not only may the rule for a perpetual annuity be objected to, but with as much justice that for a finite term of years. For instance, at 10 per cent., an annuity of 1l. for five years, is worth, according to the usual simple-interest suppositions, 25926l. A year's interest is 398381l. If this is paid away, and the balance of 1l. made up out of the principal, and so on, and it will be found that there is a sum in hand at the end of the ten years: in fact 279075l. will in this way be enough to meet all demands. But the manner in which the rule is constructed supposes the annual demands to be made up out of principal and interest in the following way, the sums before the lines showing how the pound yearly accruing due is raised, partly out of principal, partly out of interest:

<table>
<thead>
<tr>
<th>Principal</th>
<th>Interest</th>
</tr>
</thead>
<tbody>
<tr>
<td>398361</td>
<td>38926</td>
</tr>
<tr>
<td>Pay 99099</td>
<td>+ 99099  = £1.</td>
</tr>
<tr>
<td>256352</td>
<td>256352</td>
</tr>
<tr>
<td>Pay 85333</td>
<td>+ 16667 = £1.</td>
</tr>
<tr>
<td>251509</td>
<td>251509</td>
</tr>
<tr>
<td>Pay 76923</td>
<td>+ 23077 = £1.</td>
</tr>
<tr>
<td>138096</td>
<td>138096</td>
</tr>
<tr>
<td>Pay 71429</td>
<td>+ 25671 = £1.</td>
</tr>
<tr>
<td>66667</td>
<td>66667</td>
</tr>
<tr>
<td>Pay 66667</td>
<td>+ 33333 = £1.</td>
</tr>
</tbody>
</table>

While if interest were made to go as far as it could, we should have

<table>
<thead>
<tr>
<th>Principal</th>
<th>Interest</th>
</tr>
</thead>
<tbody>
<tr>
<td>398361</td>
<td>38926</td>
</tr>
<tr>
<td>32187 after paying £1.</td>
<td>-32189</td>
</tr>
<tr>
<td>26106 do. do.</td>
<td>-26101</td>

<tr>
<td>18717 do. do.</td>
<td>-18711</td>
</tr>
<tr>
<td>10581 do. do.</td>
<td>-10589</td>
</tr>
<tr>
<td>16400 do. do.</td>
<td>-16400</td>
</tr>
</tbody>
</table>

That there would remain -164l.

The truth is, that the rule for annuities by discounting at simple interest is wrong except upon the condition that principal and interest are to be rated in a specified way (which those who understand the formula will easily collect) to meet the accruing demands. And moreover, when interest is to be all disposed of first, before any principal is touched, the rules for simple and compound interest are identical.

RECEPTACULITIDES, a genus of fossils proposed by Defrance, synonymous with Isadaticus of Murchison.
RECORD. [Refining, P. C.] REFINING is a term applied to various processes in the useful arts, and especially in metallurgy, where the substances acted upon are purified by the chemical separation of dross and impurities, and of such foreign matters as may be in combination. The refining process would generally be treated of under Assaying, P. C., p. 495; and further particulars respecting the refining of the more important metals are given under Copper, P. C., p. 602; Iron, P. C., p. 54; Lead, P. C., p. 371; Steel, P. C., p. 28; and Tin, P. C., p. 472. Some writers apply the name of refining to the preparation of cast-steel, noticed under Steel, P. C., p. 3; a process which is certainly analogous, in many respects, to the processes usually undergone by the substances in the first mentioned. The term is applied to the purification of sugar, of which process an account is given under Sugar, P. C., p. 321.

REFLECTION. [Light, P. C.; Optics, P. C.] REFRACTION, DOUBLE. [Polarization of Light, P. C.]

REFUGE, HARBOURS OF. In the year 1840 a Commission was appointed 'to visit the coast between the mouth of the Thames and Selene Bill; to examine the ports with reference to their being available as places of shelter for vessels passing through the Channel in cases of distress from westward gales, and to mark places of refuge for merchant vessels from enemies' cruisers in time of war, and more especially as to their being made stations for armed steamers employed for the protection of our trade in the narrow parts of the Channel.' The result of the Report, but no measures appear to have been taken in consequence.

A Select Committee of the House of Commons on Shipwrecks, in a Report presented in 1843, recommended the formation of a refuge for vessels within the Channel, at the same time stating that they refrained from pointing out any particular situations for such harbours, from a conviction that such situations would be best decided on by a body of scientific and practical persons whose judgment should be specially and exclusively directed to the subject.

On the 2nd of April, 1844, the Lords of the Treasury, on the suggestion of Sir Robert Peel, then First Lord of the Treasury, and the Commissioners of the coast, commissioned two experienced naval and military officers and civil engineers to inquire into the most eligible situations for a Harbour or Harbours of Refuge in the Channel.

The Report of the Commissioners is dated August 7, 1844, and was presented to the House of Commons pursuant to an address dated March 6, 1845. The Treasury Minute under which the Commissioners acted assigned three principal objects of investigation:—1. the selection or formation of Harbours of Refuge for the safety and convenience of vessels navigating the Channel; 2. that in times of war, such harbours should be suitable for ships of constructing new works, as compared with the public advantages likely to result from such works. The Commissioners express their unanimous conviction that additional means of commerce and of naval defence are absolutely necessary. The harbours between Portsmouth and the Thames are only tidal harbours, and none of them is at present accessible to large steamers. The Report recommends certain ports and positions as Harbours of Refuge and Roadsteads, and certain breakwaters and military defences in connexion with them, so as not only to afford shelter to merchant ships, but by means of which, with the advantages of steam by sea, and railroads and telegraphic communication by land, the naval and military force of the country may be thrown on any point of the south-east coast in a few hours.

The following harbours and positions were especially examined:—the North Road; Harwich; Regent's; the Brake, or Small Downs; Dover; Dungeness; Beachy Head, East Bourne, and Seaford; Newhaven; Portland and Weymouth; and Ilfracombe. Of the places four were selected, Dover, Seaford, Portland, and Harwich, of which the Commissioners estimate the expense required for the construction of the works which they recommend as follows:—Dover, 2,500,000; Seaford, 1,250,000; Portland, 500,000; Harwich, 50,000. It is recommended that Dover Bay should be converted into a large harbour by means of breakwaters, with an area of 520 acres up to low-water mark, and a depth of water at least 150 feet wide at the east end. Its situation, four miles and a half from the Goodwin Sands and standing out favourably to protect the navigation of the narrow seas, is particularly suitable as a station for a squadron of ships of war. It is recommended to construct a breakwater in Woodford Road, for the protection of trade and a station for armed vessels. Portland should be converted into a large part of the island facing the bay is crown property, and contains abundance of stone: the holding-ground is exceeding good, and the island has abundance of water for the supply of ships. The island has great natural advantages for defence, and for the formation of a naval and military depot during war to any extent that may be required. Harwich Harbour, formed by the junction of the rivers Stour and Orwell, is stated to have a safe anchorage, and a holding-ground over an extent capable of containing many hundred ships. By the construction of a breakwater and dredging to get rid of certain shools, the Commissioners consider that it might be converted into one of the finest and most useful harbours in the kingdom.

The military members of the Commission recommend that casemated batteries be constructed on the breakwaters themselves, supported by defences on the shore flankng the approaches to the breakwaters and harbours.

At the end of the Report, W. Symonds, Surveyor of the Navy, says: 'I am present from this Report, because I consider the mass of evidence to be in favour of Dungeness, and because I cannot recommend a large close harbour at Dover, where the pilots consider the holding-ground generally indifferent, and a very considerable portion of them appear to be in favour of Dungeness, the Commissioners say that it is remarkable for its good holding-ground, and that 300 sail have been well sheltered in the East Bay at one time, and that more than 100 vessels may be sheltered there. However, this latter part of the Report is a matter of opinion; and at a sitting of the Commissioners, which was on the 14th of November, the Commissioners say that they have considered the report of Dungeness, and that 300 sail have been well sheltered in the East Bay at one time, and that more than 100 vessels may be sheltered there. However, this latter part of the Report is a matter of opinion; and at a sitting of the Commissioners, which was on the 14th of November, the Commissioners say that they have considered the report of Dungeness, and that 300 sail have been well sheltered in the East Bay at one time, and that more than 100 vessels may be sheltered there.

At the end of the Report, W. Symonds, Surveyor of the Navy, says: 'I am present from this Report, because I consider the mass of evidence to be in favour of Dungeness, and because I cannot recommend a large close harbour at Dover, where the pilots consider the holding-ground generally indifferent, and a very considerable portion of them appear to be in favour of Dungeness, the Commissioners say that it is remarkable for its good holding-ground, and that 300 sail have been well sheltered in the East Bay at one time, and that more than 100 vessels may be sheltered there. However, this latter part of the Report is a matter of opinion; and at a sitting of the Commissioners, which was on the 14th of November, the Commissioners say that they have considered the report of Dungeness, and that 300 sail have been well sheltered in the East Bay at one time, and that more than 100 vessels may be sheltered there.'

The Commissioners recommend further experiments as to the probability of silting in Dover Bay before anything is determined on.

The Commission of 1840 recommended three places as suitable for harbours of refuge, viz. Dungeness, Dover, and Seaford; and as of the utmost importance; Beachy-Head, as second; and Foreness, as third.

The Commissioners recommended further experiments as to the probability of silting in Dover Bay before anything is determined on.

The Commission of 1840 recommended three places as suitable for harbours of refuge, viz. Dungeness, Dover, and Seaford; and as of the utmost importance; Beachy-Head, as second; and Foreness, as third.

The Report of the Commissioners on the Subject of Harbours of Refuge, 1845.)

REGISTRATION OF BIRTHS, DEATHS, AND MARRIAGES. Parish registers were not kept in England till after the dissolution of the monasteries. The 12th article of the injunctions issued by Cromwell, Henry the Eighth's secretary, in 1538, directs that every clergyman shall, for every church, keep a book wherein he shall register weekly every marriage, christening, and death, any neglect being made penal. In the first year of the reign of Edward V. (1547) ecclesiastical visitors were sent through the different dioceses in order to enforce various injunctions, and, among others, that of Cromwell with respect to parish registers. In the beginning of Elizabeth's reign this injunction was repeated, when the register was required to maintain a register in which, among other things, they promised to keep the register-book in a proper and regular manner. In 1894 an Act (6 & 7 Wm. III. c. 6) for a general registration of marriages, births, and deaths, with the expense whereby for public use, was entitled 'An Act for granting to his Majesty certain rates and duties upon Marriages, Births, and Burials, and upon bachelors and widowers, for the term of five years, for carrying on the war against France with vigour.' It is a very long Act, in which the duties are minutely set down. A supplementary Act was passed (9 Wm. III. c. 82) entitled 'An Act for preventing frauds on the register-book, and for paying the duties upon marriages, births, burials, bachelors, and widowers.' The 52 Geo. III. c. 146 (28 July, 1813) entitled 'An Act for the better regulating and preserving parish and other registers of births, baptisms, marriages, and
burials, in England,' made some alteration in the law, chiefly with reference to having the books made of parchment or strong paper, and to their being kept in dry and well-painted iron chests.

The Registration Act (5 & 7 Wm. IV. c. 86: 17 Aug., 1836), entitled 'An Act for registering Births, Deaths, and Marriages,' was passed on the 17th of August, 1836. By the 44th section of the 5 & 7 Wm. IV. c. 86, entitled 'An Act for Marriages in England,' the provisions of this Registration Act are extended to the Marriage Act.

The general register of marriages made under the provisions of the Registration Act are the following: -- A general register-office is to be provided in London and Westminster (§ 2). Lord Treasurer and Lords Commissioners of his Majesty's Treasury to appoint officers, and register books to be filled and certified copies given (§§ 3 and 4). Regulations for conduct of officers to be framed under Section of the Secretary of State (§ 5). Annual abstract & registers to be laid before parliament (§ 6). The guardians of the poor of a union or parish shall, on the 1st of October, 1886, if the board is established at the passing of the Act, or, if not, within three months after its establishment, divide the union or parish into districts as directed by the registrar-general, and appoint registrars and superintendent registrars, if the clerk of the guardians will not or cannot execute that office (§ 7). Register-offices to be provided in each of the districts, and appointments of the officers of the superintendent-registrar (§ 9). Temporary registrars and superintendent-registrars to be appointed, for parishes not having guardians under the Poor-law Act, by the Poor-law Commissioners (§ 9). Any party may make an appointment to be vacated (§§ 10 and 11). Deputy-registrars may be appointed by the registrars (§ 12). All books, &c., to be transferred on removal of registrar or superintendent, under a penalty of committal to gaol (§ 16). A penalty and fine to be imposed in the event of being put on their dwelling-houses (§ 16). Register-books to be provided by the registrar-general, for making entries of all births, deaths, and marriages of his majesty's subjects in England, according to the forms of schedules (A, B, C) annexed to the Act (§ 17). Registrars authorised and required to inform themselves carefully of every birth and death which shall have occurred within their district after the first day of March, 1897, and to learn and register as soon after the event as conveniently may be done, without fee or reward, save as hereinafter mentioned, in one of the said books, the particulars required to be registered according to the forms of the said schedules (A and B) respectively, touching every such birth or every such death not already registered (§ 18). After March 1, 1897, parents and occupiers may within forty-two days after birth and five days after death, give notice thereof to registrar; and owners and custodians must do so forthwith in cases of foundlings and exposed dead bodies (§ 19). Parents or occupiers, on being required by the registrar to make such returns, are to make such returns within two days; and all the particulars required to be registered respecting birth (§ 20). Children born at sea must be registered by the captain (§ 21). After the expiration of forty-two days from the registration of births, the registrar of each district shall within six months, on the solemn declaration of the particulars before the superintendent-registrar, who is to sign the entry, and to receive 2d. 6d. and registrar 6s., extra fees; and no registration, after forty-two days, shall be made otherwise than as above, under a penalty of 50l. (§ 22). Births not to be registered after six months, under a penalty not exceeding 50l., and no registration after that date shall be evidence (§ 22). Name given in the birth registration may be registered within six months after registration of birth, on production of a certificate by the registrar (§ 24). Some person present at death, or occupier of house, required to give particulars of death, on application by registrar, within eight days; registrar to make entry of finding of jury upon coroner's inquests (§ 25). Registry of persons dying at sea, containing particulars, to be kept by the captain (§ 25). Registrar to give certificate of death to undertaker, who shall deliver the same to the minister or officiating person, and unless such certificate is delivered the minister must give notice to the registrar; but the coroner may order the registration of death, to give certificate thereof; and if any dead body shall be buried without the certificate of registry or of inquest, and no notice given to the registrar within seven days, the party shall forfeit 10l. (§ 27). Every register to make an account quarterly, to be verified by the superintendent, and to be paid by the guardians, as directed (§ 29). Marriage register books to be provided by the registrar general for ministers (§ 30). Marriage registers to be kept in duplicate, containing the several particulars of schedule C; and every entry made in one register to be recorded in the other register (§ 32). Duplicate and certified copies of registers of marriages to be sent to superintendent-registrar (§ 33). Superintendent-registrars to send certified copies of registers to the registrar-general, and certificates given by the persons keeping the registers, on payment of the fees prescribed (§ 35). Indexes to be made at the superintendent-registrar's office, searches allowed, and any index to be sealed, and shall then be evidence without further proof (§ 36). Ministers, &c., may ask parties married the particulars required to be registered; and willingly giving false information is perjury (§§ 40 and 41). Penalty for not duly registering births, deaths, and marriages, or for losing or injuring the registers, not exceeding 50l. Penalty for destroying or falsifying register-books, or entries therein, or giving false certificates, is felony (§ 43). Accidental errors in registering may be corrected, at any time, on the presentation of the parties (§ 44). Modes of recovering penalties of making false entry of births or deaths are not provided for by §§ 45 and 46. Registers of baptisms and burials may be kept as heretofore (§ 49). Registrar-general to furnish and make rules for registers, and which are to be published in conspicuous places of the unions or parishes (§ 60).

Another act was passed (1 Vict. c. 29—June 30, 1837), entitled 'An Act to explain and amend two Acts passed in the last session of Parliament, for Marriages, and for registering Births, Deaths, and Marriages, in England.' This act contains chiefly of arrangements necessary to extend and improve the provisions of the Registration Act.

Previous to the Registration Act coming into operation it was necessary to divide the country into districts of convenient size for equalizing the labours of the registrars by contracting the area where the population was dense and extending it where the population was thin. The Registrar-general issued a circular letter in September 1836, to the boards of guardians throughout the country, on whom devolved the duty of forming each poor-law union into registration districts, and as the unions differed much from each other in population, ranging from 2000 to 80,000, the Registrar-general left the arrangement to the guardians, and referring them to certain principles for their guidance. Parishes and townships not under the Poor-law Commissioners were formed into temporary districts, or, where more convenient, into a district already constituted in a poor-law union. To each district a registrar of births and deaths is appointed, and also a registrar of marriages; and in each union there is a superintendent-registrar. The district registrar of births and deaths is appointed by the guardians, and is always a resident in the district in which he acts. The registrar of marriages is appointed by the superintendent-registrar, subject to the approval of the guardians.

The total number of registrars of births and deaths at the end of September, 1888, was 2193, of whom 1021 were officers in poor-law unions. At the end of December 1835, the number of superintendents-registrars was 218, of whom 121 were superintendent-registrars of temporary districts; at the same period the number of registrars of marriages was 817, of whom 419 were also registrars of births and deaths. In the first year, under the new Act, there were registered in England and Wales—

Mr. Finlaison, in an estimate of the number of births, deaths, and marriages, to which, in the year 1887, registrar-general calculated the number of births at 560,085; of deaths at 335,968; and of marriages at 114,947. The approximation to deaths is remarkable, and not less so the deficiency in the number of births and deaths in the first year, which is attributed to the perfection in the registration of births, which seems to have arisen partly from the opposition of interested persons, partly from the erroneous notions of the ignorant, and partly from...
were negligence, has since been in some degree remedied, but is still imperfect.

The registrar-general, in his 6th Report, dated August 10, 1844, states, that four inspectors had been appointed to visit every district into which England has been divided, in order to examine into the mode in which the registrars perform their duties. These inspectors, among other important directions given to them, are required to see that the places of birth or death are accurately recorded; that the ages and professions of those who die are duly registered; that exertions are used to impress upon persons giving information of deaths the importance of producing a certificate of cause of death, in the hand-writing of the medical men who attended the deceased in their last illness.

By the end of 1839 about 350 new registrars had been built, and the use of temporary offices had been sanctioned in many places. The ordnance-office supplied iron boxes for holding the registrar-books of each district. By the end of September, 1838, registrar-books of births and deaths, and forms for certified copies thereof, had been provided by the registrar-general for 2192 registrars of births and deaths; and marriage register-books, and forms for certified copies, had been supplied to 11,694 clergymen of the established church, to 817 registrars of marriages, to 90 registering offices of the Society of Friends, and to 36 secretaries of Jewish scribes. They are each required to transmit certified copies on paper having a peculiar water-mark as a safeguard against the substitution of false entries, every three months, to the superintendent of each district, who transmits, once a quarter, to the registrar-general the certified copies of all the births, deaths, and marriages, which have occurred within the district during the preceding three months. These certified copies, having been deposited in the registrar-office in London, are there examined and arranged; and alphabetical indexes are then formed, and abstracts of them are compiled. In a few years millions of entries will have been made, and yet, for legal or other purposes, it will be as easy to find out the name of any individual from among so great a number as it is to find out a word in a dictionary or a cyclopaedia.

The registration for 1839 was

- Deaths: 480,540
- Marriages: 1,211,083

The improvement in the registration of births, as compared with that for 1838, is sufficiently obvious.

The registrations for 1839-40 and 1840-41 are as follows:

- Deaths: 501,589
- Marriages: 1,244,928

The number of births not registered still amounts to some of the usual annual amount, and the registrar-general is of opinion that the registration of births will not be complete until it is enacted that every father or other person, or some other qualified informant, shall give notice within a fixed period, of a birth having taken place.

In 1841 and 1842 the number of marriages celebrated according to the rites of the Established Church were:

- By special licence: 18
- Licence: 15,729
- Banns: 78,015
- Form not stated: 19,679

Total: 114,871

Other marriages not celebrated according to the forms of the Established Church:

- In registered places of worship: 5895
- In registrar's offices: 2064
- Between Jews: 68
- Between sisters: 118

Total: 6136

In each of the four years from 30th June, 1837, to July 1st, 1841, the marriages celebrated in registered places of worship and in registrars' offices were as under:

The proportion of marriages at registered places of worship and at the registrars' offices has slowly increased, and in 1842 the number of marriages so performed represented a population of about 125,000. The number of births registered in England and Wales for the solemnization of marriages was 2332 on the 30th of June, 1844. They belonged to the following denominations:

- Presbyterians: 198
- Independents or Congregationalists: 903
- Baptists: 559
- Methodists (Arminian): 456
- Methodist (Calvinistic): 26
- Roman Catholics: 204
- Foreign Churches: 5
- Miscellaneous: 40

A parliamentary paper gives the number of marriages, births, and deaths, registered in 1839, 1840, 1841, and 1842, as follows:

- Marriages: 123,150
- Deaths: 388,979

REGISTRATION (Scotland.) The registration of documents in Scotland is a great and important system intimately connected with the titles of real, heritable property, and with the execution of the law. It is thus divided into two distinct departments, which may be considered separately—Registration for Preservation, and Registration for Execution. Registration for Preservation, in its simplest form, is merely the preserving of an attested transcript of any deed in a public register, that thus an authentic copy may be had recourse to in case the original should be lost. Besides the regular statutory records of particular deeds, there are books attached to the several courts of civil jurisdiction, in which parties may for their own convenience register such documents as do not require by any special obligatory law to be recorded. It is a general rule that extracts from such records may stand in the place of the originals when these are not forthcoming, but that a party is not to found on an extract if he have the original deed in his possession and can produce it. In the case of mains, however, and other deeds, of which, as will be seen below, it is not the deed itself, but its registration, that makes the completed title, an extract from the register is the proper document to be produced. There is a certain class of actions, however, to meet which the original must be produced if it be accessible. These are called Actions of Reduction-Improvement. Such an action is raised against the party for the infringement of a deed, by some person, or object, the object is the annulling the deed on some legal ground. As a matter of form, in commencing such an action, the pursuer states, along with whatever other grounds of objection he may have, that the deed is forged, and he desires the original to be produced, that it may be judicially examined. The rule for production of the original is subject to modifications, where the ground of the action is extrinsic of anything peculiar to the original document; and if the original be lost without being intentionally destroyed, the inquiry must proceed on the extract and the other circumstances that can be adduced. It is usual to speak of registration for preservation, as being also for publication; and in this sense, when a book of such a character that to make it effectual in the grantee's favour it must have been delivered to him by the grantor, such registration is in the general case equivalent to the delivery. It will operate in this respect in adjusting questions of competing right, as where a father makes over to one child the property that, in case of his dying intestate, would go to another, and registers the deed. It is, however, to be understood, that registration could be in all cases that complete transference of property which is necessary to bar the claims of creditors under the statutes against alienations to their prejudice by in- 

Digitized by Google
and Corporation; but it does not appear to be distinctly settled what may be, with reference to various descriptions of documents, the definition of a grant (if such an estate was trans-ferred in heritage, i.e. property, the latter the attestation of the extinction of a burden, i.e. of the devolution of a temporary estate on the person entitled to the remainder. This system is such that the execution of a will or the main operative principle is, that when a title to land appears on the register, no latent title derived from the same authority can compete with it, and that registered titles rank according to the date of entry. The Act of 1617 directs the Register to execute the proper conveyance, and subsequently sell the same property to C, if C get this title first recorded; it cannot be questioned by B, who has only his pecuniary recourse against A. In this system of transactions regarding land, the public records are relied on as affording the means of ascertaining the character and title, and after they have searched for the period of prescription, or examined over a period of forty years (Paxman v. Paxman, R. C. S.), parties can trust that there are no latent rights, and may safely deal with the person who professes to dispose of any right connected with it. The origin of this system may be traced to the commencement of the sixteenth century, when the notaries were required to record their proceedings in their protocols, and the other officers connected with the feudal transfer of land were bound to make returns of their dealings made by them, render the subsequent alienation done for great sums of money altogether unprofitable; which cannot be avoided unless the said private rights be made public and registered in the proper place. The Act then appoints the scribes, revisions, &c., to be registered within three days after execution, otherwise they are to make no faith in judgment, by way of action or exception, in prejudice of a third party, who hath acquired a perfect and lawful right to the said lands and heritages: But prejudice always to them to use the said writs against the party maker thereof, his heirs, and successors. By the other clauses of the Act the superintendence of the system is given to the Clerk-Register, and the country is divided into Registration Districts. There is one defective provision in this Act, which is still in force. Parties are allowed to register their titles either in the Register for executions of the General Register at Edinburgh. It is unusual to adopt the latter alternative, and when it is followed, it is generally for the purpose of concealing instead of publishing the transaction. There was one case in which the Register had the necessity of registering a mortgaged estate in order that the mortgagee might have his title immediately registered, but was liable to have it superseded by any other person able to register a title on a warrant previously obtained. This was remedied by the Act 1628, c. 15, which gave the registered titles priority not according to the date of their execution, but to that of their registration. To prevent injustice by the accumulation of unregistered deeds at the office, a minute-book was, by a contemporary Act, appointed in Edinburgh, in which the Keeper enters an outline of each document as it is presented to him. By the present practice, when a saioe or other writing belonging to this register is presented to the keeper, he marks in the margin of the minute-book that the document is endorsed on the deed itself, and marks the date of registration. When the deed is engrossed at length in the register, a certificate to that effect is endorsed on the deed, mentioning the pages of the minute-book on which the deed is registered, and the deed is then returned. Registration volumes, with minute-books accompanying them, are from time to time issued from the General Register house, the keeper of the District Register retaining a copy of the minute-book for general reference. The real titles of all the heritable property in Scotland are thus preserved in a register and indexed, in the General Register-house at Edinburgh. When property is office by any estate, there is a search of records in all the districts for the titles offered for registration, in order to ascertain the rights of the parties treating for it. This is a certificate by the proper officer, describing all registered documents regarding that land, which have been recorded during forty years. The documents that the property may have been lately been much simplified and abbreviated by the Act 8 & 9 Vict. c. 33. It has to be kept in view that the title which may derive from the same authority within the sixty days only gives a preferable title. It is not necessary to create a title, and if the receiver of a conveyance have an absolute reliance on the integrity of the grantor and all persons through whom the deed has descended, he is not required to inspect the register before him. The simplification of the documents to be registered tends to lessen the temptation to delay their completion and registration. It is remarkable that the enlightened mind of Cromwell appears to have comprehended the utility of this system, and that he made an effort to introduce it into England. We are told by Ludlow (Memoirs, I. p. 436), 'In the meantime the reformation of the law went on but slowly, it being the interest of the lawyers to preserve the lives, liberties, and estates of the whole nation in their own hands, so that upon the debate of registering deeds in each county, for want of which within a certain time fixed after the sales, such sales should be void, and being so registered that land should not be subject to any incumbrance, this word incumbrance was not used in any other act till it took up three months' time before it could be ascertained by the committee.'

Registration for Execution of another peculiarity of the law of Scotland, although the system of warrants to confess judgment in England in some measure resembles it. The party to a solemn deed incorporates with it a clause of registration, by which, on the deed being registered in the books of a court competent to put the deed in force, the decision of the court shall be held as pronounced in terms of the deed, and execution may proceed against the party on an extract, as if it were the decree of a court. The engagement on which such execution may issue must be very distinctly set forth. Thus, if it be for payment of money, it must be for a sum named in the deed, and not for the balance which may be due on an account arising out of the transactions to which the deed refers. This method of execution was by statute (1861, c. 20) made applicable to bills and promissory notes without their containing any clause of registration. To entitle it to this privilege, the bill or note must be apparently without flaw, must bear the appearance of due negotiation, and must have been protested. The operation of this system was much widened by the Act 1 & 2 Vict. c. 114, which extended registration for execution purposes to France, Spain, and Portugal.

REGISTRY OF SHIPS. [Sips, P. C.]

REGNARD, JEAN FRANCOIS, was born at Paris, according to most accounts, in 1647, though in a short biography prefixed to a translation of his 'Meditations' (Paris, 1830), he is said to have been born in 1656. An only son and heir to considerable wealth, he received an education qualified to fit him for the position in life he was likely to occupy. The death of his father soon after he had completed his studies enabled him to gratify his desire for travelling. The first country that he visited was Italy, where he spent the year 1678, a date which, connected with other circumstances, renders it probable that 1676 was the real year of his birth. He revisited Italy a second time in 1678, on which occasion he formed an intimacy with the Eloise, whose memory he has consecrated in his pleasing little novel entitled 'La Provencale, the novel published at Algiers, which is described by the lady and her husband were induced by him to visit France, and for that purpose they all sailed from Civita Vecchia in an English vessel bound for Toulon. On the voyage, however, the vessel was taken by Algerines, and Regnard and his companions were taken captives to Algiers. The adventures of their captivity form the basis of the novel above mentioned, and they are sufficiently interesting and romantic in their own way to deserve the copyists who have set down the tale, as proceeding from the pen of Regnard. The only talent of Regnard which became serviceable to him on that occasion, was one which his love for good fare had excited, and his wealth had enabled him to gratify, the skillful preparation of which, according to the principles of Parisian cookery. His culinary abilities secured for him the good will of his master and the favour of the

§ 1'2
ladies of his household. During his captivity he was taken to
Constantinople, where he remained two years. On his re-
turn to Algiers he was ransomed for a considerable sum by
the French consul; a ransom which he carefully pre-
served. He returned, however, not having been allowed
by his unlucky adventures, and, on the 26th of April, 1681,
be set out from Paris on a journey over the north of Europe.
On arriving at Stockholm he was induced by the King of
Sweden to visit Lapland. His remark there by way of
Tornea, ascended the river of that name, and reached the
borders of the Frozen Ocean. On one of the rocks of the
mountains, amidst the summit of his excursion, he engraved
the following Latin verses.

Qulla nos genti; sive nos Africis; Gangues
Hastaeus, Capraces occisuum instruximus amnem,
Custoda in animi acta ibique magnis, etc.
Hic tandem stetimus nobis ab defunct orbis.

(Anno 1681, die 22 Augusti).

On his return from Lapland he made a short sojourn at
the Court of Sweden, and, after having travelled over
Poland, Hungary, and Germany, came to Paris on the 4th of Decem-
ber, 1688, where, satisfied with the wandering life he had
led, he determined upon settling. Having purchased some
land about seven leagues from the town, he bought a house
under government part of his time to literary pursuits, but spent the greater part
of it in the society of his friends, and in the enjoyment of the
capital; the summer he was in the habit of passing on
an estaminet called 'the tavern near Paris. He has given
ample details of his manner of life, in his 6th epistle and his
'Mariage de la folie.' His devotion to gaiety and pleasure,
as it was the means of lessening his utility and reputation
as a writer, was the cause of his untimely death, which occurred
on the 5th of September, 1710.

As a dramatic writer, the reputation of Regnard stands
deservedly high; in comedy he is generally considered second
to that of Molière. Voltaire has remarked that 'a reader can appreciate
that great dramatist who feels no pleasure in reading
Regnard.' His finest and most perfect production is the comedy of 'le Joueur,' written in 1696; some scenes in it,
more especially the thirteenth scene of the fourth act, are
equal to anything written by Molière. Himself a gambler, he
has given a dark but faithful colouring to the portraiture of
a vice which had embittered his life, and he has translated his
own sentiments on the subject into the language of the
most beautiful and energetic poetry. His next best piece
is 'le Légataire Universel,' in five acts, in which the humour and the
verisimilitude are alike deserving of admiration. (P. C. vol.
ix. 421.) Had Regnard produced many comedies of
similar merit to the two which we have mentioned, he would
have relieved French literature of the reproach which has
often so justly adhered to it of having had no Molière.
The fault into which he has fallen is that, like
Piron, Greart, and Marivaux, he has rather delineated an
exaggerated representation of some particular vice or folly
than, like the great original, human nature in its every-day
proportions. This fault however is still more conspicuous in the French
dramatists who succeeded him, whose portraits are,
in most instances, only coarsely drawn caricatures of
nature.

The other dramatic writings of Regnard, in five acts, are,—
1, 'le Distrato,' which appeared in 1697, and is taken from
one of the characters of La Bruyère. This piece failed on its
first representation, but was re-staged in 1731, reproduced
in the French stage with considerable success. 2, 'Démocratie'
(1700). 3, 'Les Ménechmes' (1705); a comedy dedicated by
the author to a friar on a reconciliation with him which his
friends had effected; between these two poets there had
been a long literary warfare [Boltz, P. C.]; it is rather an imitation of the Ménechmes of Rotrou than of the
antique comedy of Plautus. His shorter pieces are in prose;
the principal of them are,—1, 'le Divorces,' in part of Paris
(188). 2, 'la Descente de Messiz aux Enfers' (1689). 3, 'l'Homme a bonnes Fortunes' (1690); Regnard has also
written another of this comedy in a French piece of one
act which was represented in the same year. 4, 'Les Filles
Étrangées' (1690). 5, 'la Coquette' (1691); all in three
acts. 6, 'Les Chiots' (1692), four acts, and several one-
act pieces. 7, 'Cœur de Reine' (1688), a pastoral comedy
in five acts. He also wrote an opera entitled 'Le Carnaval de Venise'
(1899), the music of which is by Campra, and a tragedy
called 'Saporo,' which has not been represented. His other
works are some Epistles and two Satires, one of them
directed against Boltz, another against husbands, which
have been much admired in several shorter poems. He
has composed a relation of his various travels, and the
Provencale already alluded to.

The best editions of his works are those by Lequien,
published in 4 vols. 8vo, in 1723, 2 vols. 8vo, in 1722 and
1723, 6 vols. 8vo.

REGULATORS OF MOTION. Fly wheels are the means
usually employed to render the movements of machines
as nearly as possible those of the wind, as in the
applications of these have been described under WHEELS,
(P. C. p. 316, col. 2), and under Steam-Engine (P. C.
p. 447, col. 1). Pendulums, as regulators of clock-wheels, are described under Pendulum (P. C.); and
the Governor, by which the supply of steam is regulated, has been
described under Steam-Engine (P. C., p. 410, col. 1). Some
account of air-vessels for regulating motion in the
tread-wheels, which are employed in prisons, has been given under
Air-Vessels (P. C. S.), and it may be added that a particular
kind of fly has been occasionally used for the like purpose.
This consists of a vertical rod about 20 feet long,
carrying at its upper extremity, on opposite sides, a long
rectangular frame, which is provided with shutters turning on
hinges; by the revolution of the shaft these frames turn
round horizontally, and by the lead of two governor balls by means of wheel-work, when the motion of
the tread-wheel becomes too rapid, the diverging balls
cause the shutters to close, and thus the resistance of the air
is diminished. Similarly, when the movement of the tread
wheel become too slow, the balls collapsing allow the shutters
to open, when the resistance of the air is diminished and the
velocity of rotation increases.

REICH, ANTOINE-JOSEPH, a musical composer
and theorist, was born at Prague in 1770, and having in his
infancy lost his father, was educated first by his uncle, and
finally at the university of Bourn, where he very successfully
pursued the study of several branches of the liberal
arts, and received his degree of "maître de chapelle" to the Elector of Cologne, placed his
nephew in the same service. On the French invasion in 1794
Reicha sought refuge in Hamburg, and there composed an
opera, 'Oedipe, ou les Français en Egypte,' but it was not
represented. He then repaired to Paris, in 1798, but failed.
in his endeavour to obtain a hearing for his work, on account
of the feebleness of the drama. However he there produced
a grand symphony which met with success. In 1802
he proceeded to Vienna, and resided six years in that capital,
enjoying the friendship of Haydn and Beethoven. During
that period he published an Oratorio, and a collection of
figures. On the invitation of Prince Louis Ferdinand of
Prussia, who was a superior performer on the piano-forte,
and who desired instructions in composition from Reicha, he
prepared to go to Berlin. The amiable prince obliged him to change his intention. In 1806
he returned to Paris, and gave a course of lectures on compo-
sition, which were well attended; and some quintets for
wind-instruments which he there produced, were much ad-
mired. But an opera, 'Caglistro,' which he gave in 1810 at the
Opéra Comique, was allowed only a single representation,
and that a stormy one. In 1816 he produced, at the Académie
Royale de Musique, 'Nathalie, ou la Famille Suise,' and in
1822 'Sappho.' But this able theorist and learned harmonist
did not the talent for creating melody, which genius alone can
produce; and he might with propriety have said to his
declivities, 'Follow my precepts, but not my examples.' He then
prudently renounced the composition of operas; and having
been named professor at the Conservatoire de Musique, on
the death of Mehul, in 1818, he there attracted a numerous class
of pupils, to whom he imparted knowledge, which had
become highly esteemed masters. He originated a method of
instruction more clear and precise than any that had been in
use; and the publication of his didactic works, which soon
made these exquisite compositions by the most refined and
considerable degree improved the study and advanced the know-
ledge of music. These opened to him the doors of the
Institut de France, in May, 1855. Unfortunately for the
science, the public, however raised to this high honour
his death taking place in May, 1836. His chief works on the
theory of music are—1, 'Traité de Melodie,' 4.to. 1814;
2, 'Constitution de la Soprano ou énorme de la Hentzme de Saint Germain,' etc. He
also wrote an opera entitled 'Le Carnaval de Venise'
(1899), the music of which is by Campra, and a tragedy

Dramatique,' 4to, 1835; and many articles on music in 'l'Encyclopédie des Gens du Monde.' (Biographie Universelle.)

RELEASE REMAINDER. [RELEASE AND REMAINDER, P. 521-522.]

REMOLLEURDIES, a singular fossil genus of Trilobites found in the Silurian strata of Tyrone by Portlock, who describes it in his Geological Report on Tyrone.

Italian Renaissance properly so called is occurring, neither this nor the term Cinquecento have found their way into any of our architectural dictionaries. The term Renaissance indicates the period of the Revival, when the classical style began to be adopted as the style of the new age. But this is not the case with the term Cinquecento, which literally means five hundred, whereas it is used as equivalent to mezzo cinquecento, the middle being understood though not expressed, therefore it stands for fifteen hundred, and in its technical sense among artists signifies the style of architecture and general decoration in vogue during the 16th century, or rather the earlier part of it; nor is it so restricted, for without exact reference to date, it also applied to the style so denoted though it may happen to be before the year 1600, which period may be taken as the equator-line laid down by the historians of art. Both terms, however, are now chiefly placed by the foundryman in the common mode of that of cinquecento therefore very loosely and arbitrarily.

Although all were derived from that of Italy, each country has its own Renaissance, described severally in the French, German, English Renaissance, etc. (ELements d'Architecture, P. C. S.), preserving a general family likeness, but exhibiting traits exclusively its own. It is therefore rather simply an Italian Renaissance, or peregrine' and subject to many influences and has treated of it expressly and at due length, instead of merely touching upon it hurriedly. The Renaissance in general is usually spoken of as if it were nothing more than a direct but unattractive imitation of the antique, previously to the orders being so well understood as they were afterwards studied through the text of Vitruvius, and reduced to a methodical system of bookish rules, by Palladio and Vignola. But in the beginning of the 17th century, the ancient arch, order, and in the next, not upon the temple style of the Romans, but their triumphal arches, baths, and other edifices. It was not either the portico, or the continuous colonnade, where columnation displays itself in all its purity, that was taken as a model, but rather such structures as the Colosseum [Amphi- theater, P. C. S.], where several small orders—that is, small in proportion to the general mass—are introduced for little more than decoration to it. And in the Renaissance and Cinquecento styles, entire orders are used only as embellishment, and avowedly so. Where columns are employed for actual support, as in open loggias, it is only in combination with arches spanning the intervening space, and the arches, of course, finishing to the latter; which is regarded by some as one of the most indefensible herey and uter violation of good taste, though for no better argument than that columns were never so employed in the classical style, but ever original in simple proportion to horizontal entablature; in other words, transvection is essential to them. Essential it certainly is to the completion of an entire edifice, whether it be a church, palace, or other building. From this, good taste or good sense to employ columns as actual pillars or supports to arches resting upon them is than to employ the transvection or entablature without columns, as decoration in stayer buildings. [Antwerp, P. C. S.] In fact, a great deal of Italian Renaissance is satyr, with either a full entablature, or a cornice crowned and proportioned to the entire mass. This large and simple mode of treatment was generally given up by the middle of the 17th century, when the period of the revival, and contrasts very strikingly with the Transalpine Renaissance in France and other countries, which is characterized by multiplicity of parts, and numerous divisions and breaks. It contrasts also with the contemporary practice of the Italian architects themselves when they employed the orders, in doing which they made their compositions microcubular, applying a separate small order to each floor or horizontal division of a façade, above the ground floor; and they further reduced the height of the columns by giving a considerable proportion of each order to high pedes- tals beneath the columns. In Transalpine Renaissance such stipulations might be employed for the ground floor as well as the others, and the spaces between the columns being filled in, either entirely or nearly so, with large windows, so that the columns or pilasters between them show only as necessary to the windows them-

selves, and as narrow piers between them. Perpendicular completeness predominates, both as to the quantity of the openings occupy, and the architectural character occasioned by it. One of the earliest importations of the Renaissance into this country, by Longhouse, Wiltz, erected by John of Padua, 1567, and extolled for its fine taste 'displayed in it, is an instance of such mode of composition, and shows how greatly the borrowed style was transmitted faithfully with regard to details, among which may be reckoned the orders themselves, which amount in fact, when so applied, to no more than such.

One deviation from the Italian practice was the frequent em- ployment of coupled columns or pilasters, which was in some cases (as at Wolstanton Hall) caused by the necessity for wider piers between the windows, at the same time that the intercolumnia were completely occupied by the windows, which last, it should be observed, retained their Tudor or English character, being very spacious and divided by mul- tions and transoms.

In much of the Italian cinquecento, especially in that for which purity and correctness were affected, the character of the detail is somewhat dry and meagre, and there is very little ornamentation, even the entablatures in Corinthian and later order modelled from the antique, often by the addition of a fictitious architrave, or some other modification, as it may be distinguished for lack can be said—seems, on the contrary, to have been most in favour both in France and in our country, probably for the consequence of the taste for luxur- ious enrichment which has been indulged during the period of Gothic architecture which the new style was beginning to replace. Besides which, it was there adopted as a fashion that was long being at first employed for palatial and sumptuous structures, it was displayed in all its luxuriance. This florid species of the style and period is marked by a profusion of enrichment and carvings in mouldings and panels, by arabesque foliage and medallions, with surfaces of considerable extent are often times covered. Even the shafts of columns are frequently damasked or broidered, if not for their entire height, for a considerable portion of it, and garnished the lower one, with foliage and other chiselling; besides which they are further enriched by one or more bands embossed in similar manner. The faces both of pilasters and pedestals are also highly decorated by being pannelled, and filled up with arabesque work or other sculptures. Niches, too, are frequent features in composition, and within, their heads are generally carved to resemble a shell. Scenecutous and armorial bear- ings are not spared; neither are devices, motto, and other inscriptions. This profusion of minute ornament is eminently characteristic of the Renaissance taste in building, furniture, and decoration generally; and though it was then carried to an extreme, and the ornaments were too often uncouth, grotesque, and what is understood by the term quiet (oddly picturesque but not beautiful), much of the ornamentation is taken for more or less of fancy; therefore it would not be difficult to refine upon the style by employing it more discreetly—by selecting all its better qualities and elements, and combining them with better taste,—more sparingly. But either way it may be turned into the same composition. But architects have not distinguished between the mere copying of a former style and the free artistic imitation of it by selecting what is valuable in it, and leaving its dross, or by borrowing ideas from it and working them out afresh.

French Renaissance is truly cinquecento, since it may be dated almost with chronological precision from the year 1500, when the reign of Francis I., who was concerned in the French Renaissance, and among others the architect Giocondo [GIOCONDO, P. C. S.], who erected for Cardinal d'Amboise, the minister of that monarch, the celebrated Château Gaillon. Though that edifice—at least what remained of it, was taken down some years ago, it is known from the representations of it, and also from such fragments of it as have been preserved by being reconstructed at the Ecole des Beaux Arts, Paris, to have been an exceedingly sumptuous pile. The buildings towards the court were almost entirely erected over—some would call it 'tatoed'—with pannelled pilasters, arabesque, medall- ions, and other sculptural work. The Château of Louis XIV., restored and decorated by him, was another distinguished work of that period, and probably one of those on which Giocondo was employed. In the reign of Francis I., the culminating point of French Renaissance, the palaces erected by that sumptuous prince and his nobles
attested the magnificence if not the refinement of that age. As a retreat for himself in the immediate vicinity of his capital, Francis built (about 1580) the Château de Madrid in the Bois de Boulogne, whose façades were decorated with coloured bricks or enamelled tiles, constituting a specimen of polychrmic decoration. Of that building nothing now remains, it having been taken down at the end of the last century; but another architectural specimen of the same period, the house or castle of Francis I, erected at Montreuil, near Fontainebleau, has been preserved by being removed to Paris, where it was re-erected in its primitive state, in the Bois de Boulogne, by the architect Biet, in 1825. Of this interesting edifice, the Renaissance spirit is to be seen in the regale, in the polychrmic façade decoration, plans, elevations, and sections, which are given in Normand's "Paris Moderne," but being only in outline, a great deal of the effect is lost in them. The palace of Fontainebleau itself, in its interior at least (now restored by Louis Philippe), records the magnificence of Francis, his taste for splendour, and his liberal encourage-

ments.

In Germany, the castle or rather palace of Heidelberg would, if completed, have been a most gorgeous pile in the Renaissance style, as it showed itself in that country; and therefore the principal portion of the exterior is in sufficiently good preservation to admit of faithful restoration in a series of architectural engravings—and it is infinitely worthier of being so recorded than are the mere shapeless fragments of a few blocks of stone and columns, which are regarded as interesting and curious only because discovered where they were not before known to exist.

The architecture of Spain at various periods is as yet so imperfectly studied that very little is known of its Renaissance edifices; but from the views of some of them in the 'España Artística,' that country would appear to contain several interesting and striking specimens of the kind; and among them may be mentioned, as deserving of particular notice for the elegant taste it displays, the upper gallery of the cloister of the Convent of Huerta.

We may conclude this imperfect sketch by observing that the whole work of study and research will enable us to avoid what was faulty in it, and to catch something of its freedom and spirit without falling into the licentiousness for which it may justly be censured.

REPEAL OF STATUTES. [STATUTES, P. C.]

REPRESENTATION. [DEBENT, P. C.]

REPTON, HUMPHREY, the celebrated practitioner and writer upon his art, who first assumed professionally the title of Landscape Gardener, was born at Bury St. Edmund's, where his father held the lucrative situation of collector of Excise, May 2nd, 1792. After being placed first at the grammar-school at Bury, and then at that of Norwich, he was sent, at the age of fifteen, to sea, who intended to break the business of him, to Gorkum in Holland, in the summer of 1764; a suitable place enough for the future merchant or manufact-urer, to study to a great extent upon which he was ready, according to a remark of Repton's own, to have been his father's chief ambition for him—but almost the very worst for the future landscape gardener, Dutch gardening being the very reverse of picturesque landscaping. At the age of sixteen he returned to England, and was placed in a mer-
chant's counting-house at Norwich, but all his leisure was devoted to poetry, music, and drawing. At the age of twenty-one he married, and was set up in business as a gentleman by his father, and for a while affairs prospered with him; but after a few years took an unfavourable turn, owing to losses of vessels at sea, and other circumstances in trade; wherefore having lost both his parents he was forced to follow his own inclination. He accordingly settled at Sustead, near Aylsham, in Norfolk, where his sister resided in a house left them by their father. The change was to him a delightful one, and there he passed five years of almost uninterrupted happiness, occupying himself with farming ex-
periments, gardening, and the study of rural scenery. An event however occurred in 1753, which promised to open a widely different career from that in which he was now so happily situated; for in that year his friend and neighbour Mr. Wyndham of Felphill was appointed secretary to the Lord Lieutenant of Ireland, and Repton, feeling that as the opportunity offered here was the most likely to cause him greater happiness, and more rapidly increasing family, agreed to accompany him as his confidential secretary. The flattering expectations thus suddenly raised, were as suddenly blighted; for his patron gave up his post almost immediately; and Repton returned to Sustead and domestic privacy. There however he did not long remain, for compelled to retrench, he took a small house at Harestreet, Essex, to which he became so much attached as ever after to reside there. Just at this time (1784) he became acquainted with Mr. Palmer, who had been engaged in one of the great works of his day, and whose project he aided not only by his advice and personal exertions, but by advancing a considerable portion of his small remaining capital. Yet though the scheme prospered, Repton received no remuneration for his attention; and to put up with pecuniary loss. Thus every successive speculation and enterprise of his seem doomed to fail a proof; yet had it not been so, he might never have been heard of unless it had been through his exertions. This was the case. Whims.' Fortunately though easy he was not indolent, neither was he of a desponding temper, and he resolved to try whether he could not extricate himself from his embarrass-
ments by gratifying his own tastes at the same time, and accordingly announced to his friends his intention of practising as a 'Landscape Gardener.' The field was open, for Brown had been dead some years [Baxow's C. S.], and there was no one besides of any note. With this success his last scheme was crowned, heeds hardly he be said, for business soon began to bring upon him, and he was consulted by the owners of 'places' in almost every part of the kingdom.

The list of his Red Books alone—as he called his Reports on the seats whose grounds he was employed to lay out or improve, testifies to the great extent of his professional labours—by—of the character of his work, and the course with polished society, in which his accomplishments and good because unaffectedly amiable manners and address enabled him to sustain a proper part. Nothing proves the real worth of a landscape gardener more clearly than the corruption by sudden good fortune, or by being lifted into a higher sphere: home and domestic tranquillity were still dearer to him; and few had greater cause to be attached to a domestic circle, whose happiness was marred only by the loss of so many of its members, for out of sixteen children, only seven attained the age of manhood, and only five, to-
gether with their mother, survived him, a daughter and four sons. The second in order of merit was his brother, who adopted his father's profession, but is better known as a very able architectural antiquary; the fourth, George Stanley, who, just before his father's death, married a daughter of Lord Chancel-
cellor Eldon, was brought up as an architect.

Among the blessings which fell to Repton's lot, was that of an excellent constitution and uninterrupted good health up to January 29th, 1811, when being up in his carriage, he received a severe injury in the spine, which rendered him a long while an invalid, and he was some time afterwards at-
tacked with angina pectoris, which caused him at intervals great suffering during the remainder of his life, and carried him off three years before his death. He died at his residence on the morning of the 24th March, 1818, apparently in his usual health.

His professional publications consist of 'Sketches and Hints of Landscape Gardening,' 4to., 1755: 'Observation on the Theory and Practice of Landscape Gardening,' 4to., 1803: 'Inquiry into the changes of Taste in Landscape Gar-
dening, &c.' 3vols., 1811: 'Designs for the Pavilion at Brighton,' folio, 1808; (though these designs are said to have been the approbation of the Prince of Wales, and were, like the build-
ing afterwards erected by Nash, in a fancy Oriental style, they were not adopted); and 'Elements on the Theory, &c. of Landscape Gardening,' 4to., 1816, in which he was assisted by his eldest son. These different publications on his art, which at their original price cost collectively 202 26. 6d., and were reduced to 50s. 6d., were readily purchased by P. C. S.), in a single octavo volume, accompanied by a portrait and memoir of the author from autograph memoranda (which has here been made use of). Though this compressed and economical edition must have deplored the attractions of the larger coloured plates, the same subjects being shown in small wood-cuts, it is far more convenient as a volume for perusal and study, and moreover contains several notes and remarks by the editor.

REPUBLICATION. [WILL AND TESTAMENT, P. C.]

RESEDA/CELÉE. A natural order of plants belonging to the class of Exogona. It has a many-parted calyx; the petals unequal, often by the sectional cells; for the sake of the back, an hypogynous one-sided glabrous disk; definite stamens inserted into the disk, the filaments erec, the anthers 2-ovelled, opening longitudinally; 3-lobed 1-ovelled many-seeded sessile ovary, scarcely closed, usually with 3-6 parietal

Digitized by Google
placenta, sometimes surrounding a free central ovule-bearing body; 3 gnarled sessile stigmas; campus; oramphitropical ovules; the fruit dry and mealy, open at apex, with empty carpels surrounding a central placenta, or even hooded and 1-seeded; the seeds several, reniform, with a taper arcuate embryo without or with a few white bands. This order is soft herbaceous plants, or in a few instances small shrubs with alternate entire or pinnately divided leaves, and minute gland-like stipules. The flowers are racemose or spiral, with five petals, or rarely more, and ten stamens. The fruits are capsules, berries, or drupes. The genera Reseda, Ochrodon, Oligomeris, Holopetan, Astrocarpus, and Caylusea.

None of the species possess very active properties. Reseda luteola is the Woold, Wood, or Welch, that is used in dyeing.

It has lanceolate bluish entire or trifid leaves, a 6-parted calyx equal in length to the petals, which are finely cleft into many club-shaped divisions, the two lowest simple, the capsules 3-toothed. It is a native of the North of Africa and Egypt, but its delicious fragrance has caused it to be cultivated all over the world. It is naturally a herb, but when trained in the greenhouse it becomes shrubby. This plant is in some gardens, however, trellised, and so is extensively cultivated. The seeds should be sown in pots or transplanted into pots 4 or 6 plants to a pot 4 inches in diameter.

The instructions for growing Caryota, as for a sowing should be made in July, in the open ground, and the plants potted in September. The crop for March, April, and May should be sown in pots not later than the 26th of August; the plants from this sowing will not suffer from exposure to rain whilst they are young; they must however be protected from early frosts like the winter-crop; they are to be thinned in November, leaving not more than 5 or 10 plants in a pot; and at the same time the pots should be sunk 3 or 4 inches in some old tan or coal-ashes and should be covered with a frame, which is best kept placed fronting the west, for then the lights may be left open in the evening, to catch the sun whenever it sets clear. The third or spring crop should be sown in pots not later than the 26th of February. These must be placed in a frame on a gentle heat; and as the heat declines, the pots must be let down three or four inches into the dung-bed, which will keep the roots moist, and prevent their leaves turning brown from the heat of the sun in April and May. The plants thus obtained will be in perfection by the end of May and be ready to succeed those raised by the autumnal sowing. (1858, p. 162)

The arborescent plant is often called Tree-Mignonette. It may be propagated by seeds or by cuttings, which readily strike root. Prune and fence in dead wood. Propagate by root cuttings forward by heat. As they grow they should be tied to a stick, and all side shoots should be pinched off. As the plants attain a greater size they should be shifted progressively into larger pots.

R. phyoema has lanceolate spatulate leaves, the upper ones sometimes a little divided; the calyx 5-parted, spatulate, ciliated, much longer than the petals. It is a native of France, Austria, Italy, Switzerland, and the Levant. This plant is the species of Dioscorides, 4, 128.

R. undulata, a native of the south of Europe, with pinnatifid leaves and linear-lanceolate segments, trifid petals and 3-lobed carpels, is the Reseda pubescens of Dioscorides, 4, 150. It grows at the present day on the way-sides in Attica and Corinth.

R. tuba and R. festucacea are British species as well as R. luteola. The first has 6 very unequal petals and 3-leaf or pinnatifid leaves. It grows in waste places in chalky and limestone districts. The second has 5 nearly equal petals, with pinnatifid leaves, and grows in waste dry places near the sea.

(Babington, Manual of British Botany: Don, Gardener's Dictionary; Burrett, Outlines of Botany; Lindley, Vegetal RESULTING TRUSTS. [Trust and Trustee, P. C.] Rham, William Lewis, was born at Utretch, in the Netherlands, in 1778; and of this country his father was, we believe, a Quaker. He was educated at Westminster School, and came to England in early life. He studied for some time at Edinburgh, with a view to the medical profession, but eventually the church became his destination, and he entered at Trinity College, Cambridge. In 1806, being then in his twenty-eighth year, he took his degree, and his name appears on the Transcript as tenth wrangler. In 1808 Mr. Rham was presented by the Worshipful, worshipful, living of Winkfield, Berkshire; and a few years afterwards the Nassau family presented him to that of Fersfield, in Lancashire. He died in 1845 at Winkfield, after a short illness, on the 3lst of October, 1843.

The life of Mr. Rham was characterized by active and unremitting usefulness as a parochial clergyman. He was the friend of the poor in the district in which he lived, and was always ready to help them under the wants of the moment, and sought the means to improve and elevate as well as temporarily to benefit the objects of his benevolence. At the Winkfield School of Industry, which, under his fostering care and as a kind of shelter and refuge for the institutions in country parishes, the young were taught not only the elements of knowledge, but were instructed in useful arts, and trained to habits of industry. Such were the means by which he endeavoured to promote the best interests of his parishioners.

The school which Mr. Rham founded at Winkfield is thus described by Mr. Tremennheere, in his Report to the Council of Education in March, 1843.

This school was established in 1835 for 50 boys and 50 girls. The building consists of a house for the master and mistress, two schoolrooms, a work-shop, and a lecture-room. It is surrounded by two acres of garden, to which two more adjoining acres are last year added, and which are cultivated, by the master and the boys, with the various agricultural crops, according to the most approved method and system. The boys are instructed in all the practical arts of boys was—gardening, the use of carpenters' and joiners' tools, baking and mat making; for the girls, the usual needle-work, washing, ironing, cooking, and the common household employments, under the direction of the mistress. The master and instruction of the boys in the work-shop has been hitherto of a limited kind; but the garden presented very satisfactory evidences of their skill and industry. It is cultivated in common, with the exception of small plots about twelve feet square, which belong to the boys, and of the produce of which they keep a debtor and creditor account. The produce of the rest is sold to persons who take it off to market, and the proceeds are carried to the general account of the establishment. The crops were abundant, and more varied than it is usual to see in common gardens. Something was found to fill up every space, and to suit every spot—either one of the ordinary garden crops, or some of the useful herbs, or some kind of plant or flower; and thus a lesson of considerable use to a cottager is early communicated, in the habit of making the best of even the smallest portion of ground, however apparently unpromising. The practical instruction, and the valuable example, of which the pupils here have the benefit in their garden-work, will be greatly extended when the agricultural operations in the village are brought to the establishment. They will then enjoy the further advantage of pursuing all the details of the most skilful husbandry, under the same good guidance, namely that of the benevolent founder of this establishment, The Rev. Wm. Rham, which is well known as an accomplished agriculturalist. The school will, indeed, from that period be able to offer to the children of the agricultural labourer a course of practical training in garden and farm management of no ordinary excellence.' But it is as a scientific agriculturist that Mr. Rham's name is most widely known; and, until recently, it was perhaps better known in other countries than in England. His early connection with the Continent, which was kept up in after-life, afforded scope for observation of the husbandry of different countries; and his thorough knowledge of several living languages gave him access to the works of scientific writers on foreign agriculture. In the next place, his chemical studies at Edinburgh, while preparing for the medical profession, were of eminent service to him; and scarcely less so was the proficiency in mathematics which he acquired at Cambridge. It may safely be asserted that no other writer on agriculture ever enjoyed in so great a degree such a combination of advantages; and to his knowledge of the chemical and mechanical details of agricultural pursuits, may be attributed, through acquaintance with its routine details. We would simply refer to the article Plow, P. C., as an example of this combination of science with practical knowledge. On the application of chemical knowledge to agricultural matters, he had a practical perception of its details, and a scientific knowledge of its processes, which has probably never before been possessed by one person. Thus, above all other writers
from the poles of the battery, or rheometer, proceed the two conducting wires to the rheometer, one directly, and the other through the intervention of a slender brass-wire wound. The circuit is completed in numerous ways, but the arrangement of David and the other of brass, each about 1/4 inch diameter. On the former the wire is coiled in spiral grooves, like those of a screw, so that the several coils are isolated from one another; and the brass cylinder, with a hand wheel for turning it on its axis, in order to permit more or less of the wire on the wooden cylinder to be uncoiled from it and ground with the object, so that the quantity of wire, forming part of the circuit, may remain on that cylinder; this apparatus is called a rheostat.

In employing the instrument, an object whose resistance to the passage of the electric, galvanic, or magnetic fluid is to be ascertained, is placed so as to form part of the circuit, and the point at which the needle in the rheometer stands is to be observed; then, removing the object, and turning the cylinders till such a quantity of wire is coiled on the wooden cylinder as will bring the needle to the same point, that quantity of wire, which can be measured by a scale on the instrument, will serve to indicate the resistance caused by the presence of the object which had been interrupted, or, in voluting, electrifying; f.e., it is necessary to maintain a constant degree of energy in the current.

RHINACANTHUS (from *μον, a mont, and *δεσδος, a thorn), a genus of plants belonging to the natural order Acanthaceae. It has a regularly 6-parted calyx with small subulate bracts and bracteoles: a hypogynous capsule, with a long slender tube, the upper lip narrow, the lower trifid, with equal segments; 2 staminodes inserted in the throat of the corolla, the anthers 2-celled, awnless, with 1 cell placed above the other almost in a line; a clavate capsule much compressed at the base, with the commissure of the valves in contact and sessile; the upper part 4-seeded, or by abortion 2-seeded; the dissepiment complete, adnate; the seeds small, testarv, globular, augmented with hooks which are concave and obtuse.

R. communis is a native of the continent of India, with opposite stalked broad-lanceolate obtuse leaves, above smooth, below a little downy, often from 2 to 4 inches long and from 1 to 2 broad, and a flabby ring surrounding the base of the ovary. The roots of this plant are boiled in milk, and are reckoned by the natives of India an aphrodisiac. In conjunction with this, pepper and pepper they are used as an external application for ringworm.

R. major has linear-lanceolate serrate leaves; the flowers in racemes, are ovoid in the upper part of the corolla lobes, the bracts inciso serrate, with an attenuated point, the seeds with a very narrow membranous border. This is the plant of British botanists, but R. major is the small hamelot of the flower-gardeners. Its flowers margin to the seed, and the central part of the upper lip of the corolla as prominent as the lateral lobes. This plant is found in meadows and corn-fields in the North of England, but is West Country in its distribution.

Several other species of this genus have been described. Koch, in his ‘Flora Germanica,’ has five, — R. minor, the rirrita gali above described, R. major, R. dectororopus, R. angustus, and R. alpinus.

(Don, Gardener’s Dictionary; Babington, Manual of British Botany.)

RHYZODUS, a genus of fossil fishes from the carboniferous limestone of Scotland. (Owen.)

RHYNCOSPORA, a genus of plants belonging to the natural order Cypariceae. It has few-flowered spikelets, 0 or 7-flowered, the latter being found in the nut compressed, convex on both sides, crowned with the dilated base of the style. There are two British species: R. abeta, not uncommon on turf and bogs, and R. fuscum, a rare species from the coast of Devon in Ireland. (Babington, Manual of British Botany.)

RIBALTA, FRANCISCO, a distinguished Spanish painter of the school of Valencia, was born at Castellon de la Plana in 1551. When very young he fell in love with his master’s daughter, but the father (his name is not mentioned) would not consent to a marriage, on the plea that Ribalda was not sufficiently advanced in his profession. Upon this he determined to go to Rome, and his mistress pitied her faith to him. At Rome he studied the works of Raphael, and particularly Sebastián del Piombo, and, according to Cen Bermúdez, those of the Carracci also, but this is an error; none of them went to Rome before 1600, some years therefore after Ribalda must have left it.

Upon his return to Valencia after an absence of three or four years he immediately repaired to the house of his master, who was absent; but upon an ease in his study was standing an unfinished sketch, which the young painter as rapidly as possible completed in the presence of his still faithful mistress, and immediately retired. The father was much surprised at what he saw, and asked his daughter who had been there, at the same time observing, ‘If this were your lover, willingly should you marry him, but not the poor Ribalda.’ ‘Ribalda himself has done it,’ said his daughter, and of course the marriage took place.

Ribalda soon obtained great reputation. His first public work was the Last Supper, ordered by archbishop Don Juan de Moncada, governor of the town of the college of Corpus Christi, at Valencia. He was rewarded with the merit of a large part of the place Pedro Muñoz as St. Andrew; and as Judas, a shoemaker of the name of Prada, whose vicinity was a nuisance to him. He died in 1628, and was buried in the church of San Juan del Mercado, in Valencia.

Ribalda’s design was correct and vigorous; he was a good anatmist; and his compositions are often grand. In colouring also he was generally good, much resembling Sebastián and Titian, though occasionally dry; but the works of some of his principal scholars, as Castañel and Baus, are sometimes attributed to him. His works are or were very numerous in Valencia, and in the church of the Convent of San Luis, Castellon de la Plana, and Madrid; and some at San Ildelfonso, Toledo, Zaragona, Andilla, Algemena, Torrente, Portaceli, Morella, and Carcañate.

The Entombment by Ribalda, in the cathedral of Valencia, is an excellent work, and there are also many admirable pictures by him in private collections in Valencia, as the Conde de Parement, and the Mazques del Raful. The Convent of Santa Clara has the very beautiful Castellon de la Plana, and Madrid; and some at San Ildelfonso, Toledo, Zaragona, Andilla, Algemena, Torrente, Portaceli, Morella, and Carcañate.

Another Entombment by Ribalda, in the cathedral of Valencia, is an excellent work, and there are also many admirable pictures by him in private collections in Valencia, as the Conde de Parement, and the Mazques del Raful. The Convent of Santa Clara has the very beautiful Castellon de la Plana, and Madrid; and some at San Ildelfonso, Toledo, Zaragona, Andilla, Algemena, Torrente, Portaceli, Morella, and Carcañate.

Philanthrope.' He was best known however for a series of Essays on the principal Characters of Shakspere, which appeared in three successive volumes beginning in 1776, and were in 1797 collected into one volume, which became very popular and has been reprinted several times. Those essays show considerable critical talent, and some eloquence in writing: their chief fault is the depreciatory spirit in which they treat the great poet, and which has exposed them to severe censure from Mr. Knight and some other recent critics.

RICKMAN, THOMAS, a distinguished writer on Gothic and other works has become a standard authority in this country, and in whose work there is something remarkable: for though neither his education nor his first pursuits in life were calculated to direct his attention to the study of architecture, while the religious tenets in which he was brought up by his parents (those of the Society of Friends) were ill fitted to inspire a taste for that particular branch of the art which he especially cultivated, he not only made it his study, but when he had reached the meridian of life, took up architecture as his profession, and obtained extensive practice.

He was born at Maidenden June 8th, 1776, and brought up by his father, who was a surgeon and apothecary in that town, to the same profession. He went in 1797 to London, where he became for a while assistant, first to Mr. Stringer, chemist to the royal family, and next to Mr. Atkinson, in Jersey Street. On quitting the chemical, he changed his situation only but his vocation also, and entered into the employment of Messrs. Day and Green, extensive grocers, at Saffron Walden. His residence at Saffron Walden was not happy, his persistence being cause of frequent and heavy bills which his father, who was anxious that he should complete his medical education, he went again to London, and 'walked the hospitals' after which he returned, in 1801, to his father who was then settled at Lewes, but did not remain with him above two years, when he repaired again to the metropolis, and engaged himself as clerk to a corn-factor,—a step likely to lead him farther from than bring him at all near his professional destination. Nevertheless it proved a stepping-stone to him, so far that he became a partner in the business. In 1808, about the time of the death of his first wife (his cousin Lucy Rickman, to whom he had not been married above a year), he removed to Liverpool, where he made another change, for he took a situation in the counting-house of one of the principal insurance-brokers there. Uncongenial and unsparing as it apparently was in itself, this new situation proved the making of his fortune and fame; for as the attention to business it required occupied him only a few hours in the day, he devoted his leisure to the study of architecture. But here there is evidently a gap in this most interesting and exciting phase of his career, for we are left altogether in uncertainty as to the influence or impulse which directed him to a pursuit so remote from his habits and employments.

However, having once taken up the study he pursued it zealously; examined ancient buildings with diligence—in a word, educated himself; and perhaps saw all the clearer because he was not trained in his inquiries by the prejudices and conventionalities of a professional education. He was also industrious with his pencil, and carefully noted all those distinctions in the different modes of the pointed style on which he founded his valuable system of classification for it. About this period he married his second wife, Christiana Horner, sister to Thomas Horner, the artist who painted the large panorama of London, in the 'Colosseum,' in the Regent's Park.

On the grant of a million for additional churches being made by Parliament, Rickman, who had previously made attempts at original design, became a competitor, and a determined one in the contest. He was determined to establish himself as an architect; he quitte Liverpool and removed to Birmingham, as being in his opinion a likelier situation for obtaining practice from various quarters. Having no practical experience of that time himself, and being unacquainted with the business routine of the profession, he engaged Mr. Henry Hutchison as his managing assistant in all matters of business, and after his death (1830) entered into partnership with Mr. Hussey.

In 1835 he married his third wife, Elizabeth Miller, of Edinburgh, by whom he had a son, and who survived him. Some years previous to his decease he had had an apoplectic attack, but his naturally strong constitution prevailed against its effects, and he continued to exercise his profession up to the time of his death, which happened March 4th, 1841.

Had Rickman been known only as a writer, his ' Attempt to discriminate the Styles of Architecture in England' (originally written for the Transactions of the Society of Science and Art, but greatly extended as a separate work, and improved in each fresh edition), it would have obtained for him celebrity, for it has become a standard book, and is almost indispensable to the student. Nevertheless it is omitted among those on the subject of Gothic architecture, of which a list is given in Gwilt's Encyclopedia. The work itself, however, recommended him to all classes of architecture, opened the road to extensive practice, and procured him patronage in very innumerable quarters, where as a sertician he could hardly look for direct countenance and employment. It is to be observed however that 'latterly'—by which it is no doubt is to be understood when his profession brought him into contact with the clergy—he withdrew from the Society of Friends. In all probability he had already done so when he was employed at Cambridge and at Rose Castle, the palace of the Bishop of Carlisle, which was restored by him.

At Cambridge he executed the new court and buildings (begun in 1827) of St. John's College. Perhaps hardly any individual in the profession was ever employed upon so many churches as Rickman, and a list of them and of other buildings by him is given in the 4th edition of his book; but, long as it is, that list is incomplete, because it does not come down later than 1835. It also be to be remembered that it is a mere list, without so much as any dates. This is it is to be hoped will still be done, and the list itself completed in the next edition of the work, which we understand has been long in preparation. Notwithstanding this a full memoir of Rickman will then be given; and one very desirable improvement it would be were a descriptive catalogue of his buildings to be illustrated by wood-cuts of them— if not of all, of the best. Such a catalogue would be useful for the student which pass over the pulleys or the axes of the wheels; and, in order to understand how this condition affects the relation between the moving power and the resistance, let it be observed that when a stiff rope is bent over the upper part of a wheel or pulley in a vertical plane, for example, the weights or powers applied at its extremities may not be sufficient to draw the descending portions into the positions of two vertical lines. Now, if one of the parts of the rope should take such a direction that a vertical line drawn through the weight attached to that part, cuts the horizontal diameter of the wheel or pulley at a point between the centre and one extremity of the circumference, for we are speaking of a curve represented by r and z respectively, the corresponding weights by W and W' and the radius of the wheel by R; the conditions of equilibrium instead of being W = W' will be

\[ W \left( R - z \right) = W' \left( R + z' \right) \]

But, if W be the weight by which descending mixes up the other, the value of z is generally so small that it may be disregarded, so that we have, in the case of equilibrium,

\[ W = W' \left( R + z' \right) \text{ or } (W - W') = W' z' \]

or again, 

\[ W' = \frac{W - \left( W + W' \right) z'}{R} \]

that is, in order to put the system in a state of equilibrium, the excess of W above W' should be equal to $W' z'$.

The formula given by Coulomb to express the forces necessary for overcoming the rigidity of a rope, or the equivalent of $W' z'$ is

\[ \frac{W}{R} \left( \frac{a+bW}{a+b} \right) \]

r being the semi-diameter of the rope, a the force arising from the warping or twisting of the rope, and b that which depends on the tension arising from the weight W; the values of a and b may be determined by experiments made under...
with cords of different diameters; and thus \( \pi \) may be found. M. Coulomb ascertained that for slender string, \( \pi = 1 \), and that for stiff cordage the value of \( \pi \) varied from 1 to 2; also, from some experiments made with ropes consisting of 20 strands of hemp, he determined that the weights requisite to overcome the rigidity, when the ropes passed over a pulley four inches in diameter, and were strained by weights equal to 25 lbs., 125 lbs., and 425 lbs., were 5 lbs., 25 lbs., and 125 lbs., respectively.

Unfortunately, ropes of equal dimensions differ much in rigidity, so that little dependence can be placed on the results of general formulæ in estimating its value. While ropes which are dry and those which are dry and the rigidity of ropes is greatly increased by tarring them. In general the weights necessary to overcome the resistance of tared ropes is proportional to the number of the threads of which they are composed.

RINCON, ANTONIO DEL, court painter to Ferdi-

nand and Isabella, and the first good Spanish painter, was born in Guadix in the middle of the fifteenth century, or probably as early as 1446. From the largeness of his style compared with the generally then prevailing Gothic design, not only in Spain but in the greater part of Italy, he is supposed to have studied in Florence, and probably with Andrea del Castagno, or with Simone degli Spigoli. Most of Rincon's works have already perished, but there is still an altar-piece, consisting of seventeen pictures from the life of the Virgin by him painted, now in the church of Santiago, in Madrid to Avila, the Escorial, which display many excellent qualities of art. In 1483 he executed some works in the old sacristy of the cathedral of Toledo; he was employed by Ferdinand for the construction of the Escorial and the churches of Spain, but both pictures and palaces have long since perished by fire, and otherwise. Rincon was decorated with the order of Santiago; he died at Seville in 1500. Antonio's son, Fernando del Rincon, was a good fresco painter.

(Coon Bermudes, Dicionario Histórico, &c.)

RIZI, DON FRANCISCO, a distinguished Spanish painter, was born at Madrid in 1608. He was the pupil of Vincenzo Cardano, and had the extraordinary reputation of invention and execution, but was at the same time, as is usual in such cases, superficial and incorrect: still his readiness to design and facility to execute ensured him a brilliant career. It was not till 1666, however, that he was appointed principal painter to Philip IV.; and he held the same place under Charles II., who gave him the additional place of deputy keeper of the royal keys. He was appointed in 1658 painter to the cathedral of Toledo, a post often in Spain more important than that of painter to the king, for he has the charge of all existing works in the cathedral, and generally the execution of all new works undertaken in his time, which in Spain is a matter of property and habitation, and so much the more important. Francisco Rizi is, however, one of those painters to whom the decline of painting in Spain is attributed, through the mere superficial attractions of his works; and he is said also to have done great injury to the taste of the period. It is said that Rizi's last work was a sketch for the great altar-piece of the Retablo de La Santa Forma in the Sacristy of the Escorial, which Charles II. ordered for the veil of the magnificent tabernacle and altar, which Rizi also had assisted in making, to contain the Host (La Santa Forma). The subject was the ceremony of the Collocation of the Host by Charles II. in 1684; but Rizi died the following year at the Escorial, having only executed the sketch; the picture was painted by Coello from a sketch of his own, and it is one of the finest pictures in Spain. [Coxe, CLAUD, F. C. S.]

The Retablo de la Santa Forma Incorrupta is the miraculous wafer which bled at Gorkum in 1525 when trampled on by the followers of Zwingli. Rudolf II., Emperor of Germany, gave it to Philip II. of Spain, whither it was transported in 1592. It has the present gorgeous altar and tabernacle for its reception, and the present altar-piece is the ceremony of its collocation. The altar is inscribed—En magni operis miraculis, in mini mirabilis Dei. It is supposed that he is the original from which the forms are exhibited for adoration, the picture, which forms a veil, is let down, and is accordingly much injured. The French, under La Houssaye, who pilfered the Escorial in 1808, carried off silver covers to adorn the tabernacle; the monks hid the wafer in a cellar, and it was restored with great pomp by Ferdinand VII. in 1814.

The pictures, both frescos and in oil by Rizi, are very num-

merous; there are several in the Museo of the Prado at Madrid, and many in the churches of Madrid and Toledo, especially in the cathedral of Toledo. Fray Juan Rizi, Francisco's elder brother, born at Madrid in 1556, was also an eminent painter and in the Benedictine monastery of San Martin at Madrid. His design was more correct than his brother's, and his pictures are distinguished for force of light and shade. He retired to Rome and joined the Benedictines of St. Pius V.'s. He was made an archbishop, in 1675, by the pope Clement X., but he died in the same year at Monte Cassino before entering upon the duties of his office.

ROADS. In Scotland the public highways used for purposes of general transit throughout the country, and suited for the use of vehicles, are under three separate kinds of management. The country in general, with the exception of some Highland districts, is penetrated by turnpike-roads managed by district trusts in terms of local statutes. These are interpreted along with the Act 1 & 2 Wm. IV. c. 49, for the general regulation of turnpike-roads. According to returns of the rents of the various bars, the smallness of the sum at which bars are occasionally farmed is conspicuous. Thirty-six bars bear to have been let for sums not exceeding 20l. each, and the number let at sums between 20l. and 100l. is 338. [Local and Revenue, 1844, p. 93.] It is obvious that in such a system the rent of the bars, which is the sum available for expenditure on the roads, must be very small in proportion to the expenses of the road-lessee who pays 10l. or 20l. a year must collect an additional sum sufficient for his own support. The highways throughout the country, which are neither turnpikes nor part of the system to be presently noticed, are called 'commutation roads.' The management of these roads is settled by local Acts referring to the several counties. From various reports made to parliament, it appears that the counties are divided into small districts, generally corresponding with the parochial division, and that the sums collected throughout the counties are distributed among these districts, and subjected to management and disbursement by petty local boards, more apt to consider the convenience of the roads in reference to their own profit by selling the tolls than to do any good to the public. A third system of roads is under commissioners appointed in terms of statute (59 Geo. III. c. 135), called the Commissioners of Highland Roads and Bridges. One fourth of the expenses of these roads are paid annually by the exchequer, and the other three-fourths are assessed on the proprietors of land in the several Highland counties. The commissioners make an annual report to parliament. By the 4 Geo. IV. c. 56, provision was made for the lapsed proprietors and the commissioners of supply of any of the counties, agreeing to relieve the parliamentary commissioners of the burden of any of these Highland roads, and supporting them by the produce of tolls.

The law as to footpaths and other roads which do not belong to any of the above three systems, is not in a very clear state in Scotland. The right of transit in such cases is founded on the Roman system of 'viridarium,' under which where the public enjoy it, it generally rests on the title of the occupant of some districts of land having a right of pathway through some adjoining place. Sometimes the right is of a purely private character, and confined to the proprietor or tenant of some tenement. At other times it is in the possession of a community, as a village or parish; and in such case it is not lawful to stop any person who may use the path, on the assumption that it is the property of the public. Such paths are virtually public; but there is no such principle applicable to them as that which stamps the publicity of a highway in England by rendering the public liable to repair it.

ROASTING is that culinary process by which meat is brought from a raw to a cooked state more directly by the action of fire than by any other means except that of broiling.
By the latter, the heat is applied immediately and suddenly to the surface, by which it is hardened, so that the juices of the meat are entirely retained, evaporation being thereby prevented; while by the former the heat is applied gradually, the watery portion is evaporated, as well as the fat melted out to a considerable extent, till the progressive browning and hardening of the surface prevent the escape of the juices. The loss of weight in roasting meat is much greater than by boiling: by this latter process, mutton loses one-fifth, and beef one-fourth, but by roasting, these losses are about one-third of the initial weight; the loss arises from the melting out of the fat, and the evaporation of the water; but the nutritious matter remains condensed in the cooked solid. Thus, while in boiling, largely partly destroyed. Roasted are therefore more nutritious than boiled meats.

(Paris On Diet.) The digestibility is also increased, especially in young meats, which are deficient in osmosis, to which the sapidity is mainly owing, and which during boiling passes into the water employed, while in roasting it is powerfully developed and almost entirely retained. Young and viscid food, therefore, such as veal, chickens, &c., are more wholesome when roasted than when boiled, and are more easily digested. The best and most tender meat may, however, be rendered hard and indigestible by a careless or ignorant cook. Everybody knows the advantage of slow boiling—slowly and leisurely)—as stated by Dr. Cuthbertson,

Cook’s Oracle, in which the most sensible and racy instructions on this head are given.

The digestibility is increased by the meat being well done, roasted or boiled; for though the latter state is not contain most nutriment, yet it will be less digestible on account of the density of its texture. This is of importance to remember when it is intended for the diet of convalescents, for what the above best meats are served.

ROOTAN, or Rattan, is an island in the Caribbean Sea, opposite the coast of Honduras, one of the states of Central America. It lies between 10° 5' and 10° 10' N. lat., and between 86° 5' and 86° 3' W. long., and is about 700 miles from Margarita, north-east to west-south-west about twenty miles, or some- what more; the width in no part exceeds five miles, which is about its breadth for the greater part of its extent. The area hardly exceeds 60 square miles. This island is one mass of rocks, but covered with a deep soil, which, united to a moist and warm climate, produces an unusual abundance of vegetation. It is overgrown with high trees, except at the western end, where there are some savannahs, on which formerly mules and other cattle were raised. The highest part of the rock is 800 feet above the sea-level. The woods abound in deer, wild hogs, geese, cattle, pigeons, parrots, and other birds, many of which afford excellent food. The whole coast swarms with fish and turtle. On the southern shores are three small harbours, Port Royal, Dixon’s Cove, and Cosan’s Cove. This island was discovered by Columbus on his fourth voyage, in 1502, and was formed a settlement in 1509, when they had numerous settlements on the Mosquito shore, but it was abandoned in 1785, when the English withdrew their garrisons from the Mosquito Shore. In 1784, when the Colonists of the Island of St. Vincent, several islanders of the English and were compelled to submit, nearly all the prisoners with their families were transported to Roatan. But they soon abandoned the island, and passed over to the continent of America, where they settled near Trujillo, in which town their descendants still form the bulk of the population. When Orlando Roberts visited Roatan (1822), it was uninhabited. But it appears that more recently some families have again settled there, under the protection of the government of Belize, especially for the purpose of fishing and taking turtles. (Henderson, Account of the British Settlement of Honduras, &c.; Orlando Roberts, Narrative of Voyages and Explorations on the East Coast and in the Interior of Central America.)

ROEBUCK, JOHN, M.D., the son of a Sheffield manufacturer, born in 1718, received a liberal education at Northampton under Dr. Doddridge. On entering on the Medical, Roebuck, an extensive refinery and chemical manufacturer at Birmingham. He there effected such improvements in the manufacture of sugar, that of course (formerly called vitriolic acid, or oil of vitriol), by the use of his patents, and by other modifications of the process, as enabled him to reduce its price from sixteen-pence to four-pence 19 lb., and thus to render it available for many new and important purposes. In 1774, he married Jane, daughter of Mr. Ford, of Worthington, with whom he was acquainted in his early days.

The inventor, to thank the many friends who have contributed to his success, in 1766, established a works at Carron (Carron, P. C., p. 519), for the purpose of bringing these improvements into practice, thereby rendering a great service to our domestic sugar manufacture. Abandoning the chemical practice, Roebuck henceforward resided chiefly in Scotland, where he perfected improved methods of smelting and manufacturing iron with pit-coal instead of charcoal, and in 1780, he erected a large works at Carron, for the purpose of bringing these improvements into practice. The furnace which he constructed in Carron was the first furnace in Great Britain, and the first furnace which was established in the history of British manufactures, was blown on the 1st of January, 1760. Fortunately for himself, Roebuck subsequently became the lessee of extensive coal and salt-works at Borrowstounness, belonging to the Duke of Hamilton. For the carrying on of these works, on which he employed nearly a thousand persons, he was obliged to withdraw his capital successively from his other undertakings, and he never afterwards returned to his chemical practice, to the great loss of science, and to the very serious loss of his clients. He was the author of the modern steam-engine, in the first patent for which he had a share. He died on the 17th of July, 1794. In a copious memoir in the fourth volume of the Transactions of the Royal Society of Edinburgh, his life and work is narrated. Many of his chemical works, especially the author of the modern steam-engine, in the first patent for which he had a share. He died on the 17th of July, 1794. In a copious memoir in the fourth volume of the Transactions of the Royal Society of Edinburgh, his life and work is narrated. of pictures in Seville [POCHECO, P. C. S.], reproached Roelas with want of decorum in a picture, in the Merced Calzada, of St. Anne teaching the Virgin to read, for representing some sweaters and a woman in the picture. He might have been excusable for not being able to read the picture; and also for painting a sheet, intended to wrap the infant Saviour in, who is naked, in the picture of the Nativity, in the chapel of the university.

Moreover, the second picture of the series by Carracci; he is the best of the Andalucian painters in design and composition, and displays frequently a grandeur of form and majesty of character which belong only to the greatest masters: in contrast, Roelas, in view of his success, has a very weak picture of the last picture is apparently the Nativity, at Olaviers. Palamos’s account of his painter is almost wholly incorrect; he calls him Doctor Pablo de las Roelas.

(On the History of Art, p. 123.)

ROEMERIA (named after Dr. John James Römer, professor of botany at Landshut; he was author of several botanical works, and died in 1830), a genus of plants belonging to the natural order Papaveraceae. It has 4 petals, numerous stamens, 2-4 sepaline stigmas, an elongated 2-4-valved 1-celled capsule with distinct placenta. The species are annual herbs yielding a yellow juice, with violet flowers.

R. hybrida, Hybrid Roemera, has a 3-valved erect pod with a few rigid leaves at its extremity. This plant is a native of Europe and the north of Africa, in cultivated fields and vineyards, especially on the coasts of the Mediterranean. It may be found in England, as it is frequent in Cambridgeshire and Norfolk. Although now having the appearance of a native, this plant has been probably introduced into this country. Two other species, R. refracta and R. roemera, have been described, the first a native of Tauria, the second of Syria.

(Den, Gardener’s Dictionary; Babington, Manual of British Trees, p. 37.)

ROMAN ARCHITECTURE. [CIVIL ARCHITECTURE, P. C.]

ROMAN CATHOLICS AND JEWS. An act was passed on the 18th August, 1846, 9 & 10 Vict. c. 59, intituled ‘An Act to regulate Her Majesty’s Suffering from Penalties and Disabilities in regard to Religious Opinions.’ This act repeals the statutes or ordinances and the several acts, statutes or ordinances as far as such parts of any of the said acts as are herein after specified, that is to say—The statute or ordnance of the fifty-fourth and fifty-fifth years of the reign of King Henry III., and the statute or ordnance commonly called Statutum de Judaismo. The effect of the repeal of these statutes may be understood by referring to the article Jews, P. C. The Statutum de Judaismo was made in the third year of Edward I. It was a law of the Realm, or any domain therein or country by virtue of the power, dominion, or obesiance of his highness, that it may be used as a form of punishment, or any other thing to extinguish anything of the extinguishing, advancement, setting forth, maintenance, or defence of any such pretended or usurped jurisdiction, power, dominion, or any part thereof, or to abet, aid, procure, or counsel any person so offending; provided always, and be it declared, that nothing in this enactment contained shall authorize or render it lawful, or permit any person to stand, set forth, maintain, or defend any such power, pre-eminence, jurisdiction, or authority; nor shall the same extend farther than to the repeal of the particular penalties and punishments therein referred to, but in all other respects the law shall continue the same as if this enactment had not been made: provided further, that if any such person in holy orders according to the rites and ceremonies of the United Church of England and Ireland shall stand, set forth, maintain, or defend any such power, pre-eminence, jurisdiction, or authority, such person shall be incapable of holding any ecclesiastical promotion, and, if in possession of any form of canonical dignity, be deposed thereof by due course of law, in the same manner as for any other cause of deprivation. Also so much of another act passed in the first year of the same reign’s reign, 9 & 10 Vict. c. 1, intituled Uniformity of Common Prayer and Service in the Church, and Administration of the Sacraments, and of another act of the parliament of Ireland passed in the second year of the same reign’s reign, 9 & 10 Vict. c. 1, intituled Uniformity of Common Prayer and Service in the Church, and the Administration of the Sacraments, as relates to a person’s residing to his parish church or chapel accustomed, or, upon reasonable let thereof, to some usual place where
common prayer and such service of God as in such acts are mentioned are used in such time of let, upon Sundays and other days ordained and used to be kept as holy days, and to be observed with special devotion and prayer, according to the use and practice of the common prayer, preaching, or other service of God there used and ministered: [The penalties from which persons are hereby relieved will appear by referring to Law, Crim. P. C. S., p. 179.]

Also an act passed in the fifth year of the same queen's reign (5 Eliz. c. 1), intituled 'An Act for the Assurance of the Queen's Royal Power over all Estates and Subjects within England: [Law, Crim. P. C. S., p. 178.]

Also an act passed in the thirteenth year of the same queen's reign (13 Eliz. c. 2), intituled 'An Act against the bringing in and putting in execution of Bulls, Writings, or Injunctions, and other superstitious Things from the See of Rome,' so far only as the same imposes the penalties or punishments therein mentioned; but it is hereby declared that nothing in this enactment contained shall authorize or render it lawful for any person or persons to import, bring in, or put in execution within this realm any such bulls, writings, or instructions, and that in all respects, save as to the said penalties or punishments, the law shall continue the same as if this enactment had not been made.

Also an act passed in the twenty-ninth year of the same queen's reign (29 Eliz. c. 6), intituled 'An Act for the more speedy and due Execution of certain Branches of the Statute made in the twenty-first year of the reign of Queen Elizabeth, and for the more speedy and due Execution of the Statute of the said Queen's Majesty, intituled 'An Act to retain the Queen's Majesty's Subjects in their due Obedience.' [Law, Crim. P. C. S., p. 179.]

Also an act passed in the first year of the reign of King James the First (1 Jac. I. c. 4), intituled 'An Act for the due Execution of the Statutes against Jesuits, Seminary Priests, Recusants, &c.' [Parent and Child, P. C.]

Also so much of an act passed in the third year of the reign of the said King James the First (3 Jac. I. c. 1, § 2 in part), intituled 'An Act for a public Thanksgiving to Almighty God every Year on the Fifth Day of November,' as enacts 'that all and every person and persons inhabiting this realm of England and the dominions of the same shall always upon that day devoutly and faithfully resort to the parish church or chapel accustomed, or to some usual church or chapel where the said morning prayer, preaching, or other service of God shall be used, and then and there to abide orderly and soberly during the time of the said prayers, preaching, or other service of God there to be used and ministered.'

Also an act passed in the said third year of the said King James's reign (3 Jac. I. c. 4), intituled 'An act for the better discovering and repressing of Popish Reconciliations.' [Law, Crim. P. C. S., p. 179.]

Also an act passed in the seventh year of the same king's reign (7 Jac. I. c. 6), intituled 'An Act for administering the Oath of Allegiance, and Reformation of married Women Reconciliations.'

Also so much of an act passed in the thirteenth and fourteenth years of the reign of King Charles the Second (13 & Car. II. c. 4, § 11), intituled 'An Act for the Uniformity of the Publick Prayers and Administration of Sacraments, and other Rites and Ceremonies, and for establishing the Form of making, ordaining, and consecrating Bishops, Priests, and Deacons in the Church of England,' as makes any schoolmaster or other person instructing or teaching youth in any private house or family as a tutor or schoolmaster punishable for instructing or teaching any youth as a tutor or schoolmaster before licence obtained from his respective archbishop, bishop, or ordinary of the diocese, according to the law and statutes of this realm, and before such subscription and acknowledgment made as in the said act is mentioned.

Also so much of the last-mentioned act whereby any act or prayers be not reformed before required or confirmed to be a force. [Law, Crim. P. C. S., p. 179.] This statute against teaching in a private house or family has long since fallen into disuse, but the formal repeal of it is an admission of the right of such teaching, which is still attended with the same threats of interference from the Church [Constitutions and Canon, Ecclesiastical, P. C. S.], which goes further than the statute of Charle., II., but this can be safely neglected by any teacher to be taught by any person in 'private house.' The canon forbids only men from teaching without licence or subscription. At that time of day women probably did not teach.

And also so much of any act or acts of parliament whereby the said parts of the said act of the thirteenth and fourteenth years of the reign of King Charles the Second herein-before repealed have been confirmed or incorporated in any other act or acts of parliament, as the same are not in any wise to be considered during the said times as parts of any of the common prayer, preaching, or other service of God there used and ministered: [The penalties from which persons are hereby relieved will appear by referring to Law, Crim. P. C. S., p. 179.]

Also so much of an act of the parliament of Ireland passed in the seventeenth and eighteenth years of the reign of the said King Charles (17 & 18 Car. II. c. 6, § 1, [1]), as requires any such persons as tutors or schoolmasters to take the oath of allegiance and supremacy, and makes such schoolmasters or other persons punishable for so instructing or teaching youth in private houses obtained from their respective archbishop, bishop, or ordinary of the diocese, and before such subscription and acknowledgment made as in the said act is mentioned.

Also so much of an act passed in the thirtieth year of the reign of the said King Charles (30 Car. II. st. 2, § 5 in part), intituled 'An Act for the more effectual preserving the King's Person and Government by disabling Papists from sitting in either House of Parliament,' as enacts that 'every person now or hereafter convicted of Popish recusancy who hereafter shall, at any time after the said first day of December, come advisedly into or remain in the presence of the king's majesty or queen's majesty, or shall come into the court or house where they or any of them reside, as well during the reign of his present majesty (whose life God long preserve) as during the reigns of any of his royal successors, kings or queens of England, so shall be liable to such penalties and forfeitures, and disabilities in this act mentioned or contained.'

Also so much of an act of the parliament of Scotland passed in the eighth and ninth year of the first reign of King William and King Mary (8 & 9 W. III. c. 3, § 8), intituled 'An Act for preventing the growth of Popery,' and all laws, statutes, and acts of parliament revived, ratified, and perpetually confirmed by the said act of King William's first parliament, except as to the form of the formula in such last-mentioned act contained.

Also so much of an act passed in the eleventh and twelfth years of the reign of the said King William the Third (11 & 12 W. III. c. 4), intituled 'An Act for further preventing the growth of Popery.' [Law, Crim. P. C. S., p. 178; Parent and Child, P. C.]

Also so much of an act passed in the first year of the reign of Queen Anne (1 Anne, st. 1, c. 30), intituled 'An Act to oblige Jews to maintain and provide for their Protestant children:

'This statute empowered the Lord Chancellor, on complaint being made to him, to order a Jewish parent to allow his Protestant children a maintenance suitable to the fortune of the parent. [Parent and Child, P. C.]

Also so much of an act of the parliament of Ireland passed in the second and third years of the reign of King George the Second (2 Geo. II. c. 17), intituled 'An
Act for securing the Estates of Papists conforming to the Protestant Religion against Disabilities created by several Acts of Parliament relating to Papists; and for rendering more effectual the several Acts of Parliament made for Inventing in the two Universities of Dublin and Oxford, the Presentation of Benefices belonging to Papists, except so much of the said act as relates to any adswonon, or right of presentation, collation, nomination, or donation of or to any benefice, prebend, deanery, or other church, hospital, collegiate, or collegiate, or any gift or grant or avoidance thereof, or any admission, institution, or induction to be made thereupon, but so as that the repeal of the said act shall not in anywise affect or prejudice the rights and liberties of the inhabitants of the said two universities, tenants, tenements, or hereditaments under and by virtue of the provisions of the said act at the time of such repeal.

Also so much of an act of the parliament of Ireland passed in the seventeenth and eighteenth years of the reign of King George the Third (17 & 18 Geo. III. c. 49, s. 1[1]), intituled "An Act for the Relief of His Majesty's Subjects of this Kingdom denominating the Popish Religion," as entails that no maintenance or portion shall be granted to any child of a Popish parent, upon a bill filed against such parent pursuant to the aforesaid act of the second of Queen Anne, out of the personal property of such Papists, except out of such leases which they hereinafter take under the powers granted in this act.

Also so much of an act passed in the eighteenth year of the reign of King George the Third (5 Geo. II. c. 60, s. 5), intituled "An Act for relieving His Majesty's Subjects professing the Popish Religion from certain Penalties and Disabilities imposed on them by an Act made in the eleventh year of the reign of the said King," and also of the Third, intituled "An Act for the further preventing the Growth of Popery," as entails that nothing in this act contained shall extend or be construed to extend to any Popish bishop, priest, Jesuit, or schoolmaster who shall not have taken and subscribed the above oath in the above words before he shall have been apprehended, or any prosecution commenced against him.

Also so much of an act of the parliament of Ireland passed in the twenty-third and twenty-fourth years of the reign of the said King George the Third (23 & 24 Geo. III. c. 58 [1]), intituled "An Act for extending the Provisions of an Act passed in this Kingdom in the nineteenth and twentieth Years of His Majesty's Reign, intituled "An Act for naturalizing such foreign Merchants, Traders, Artificers, Artists, Manufacturers, Workmen, Seamen, Farmers, and others, as shall settle in this Kingdom," as entails that out of the benefit of that act persons professing the Jewish religion.

Also so much of an act passed in the thirty-first year of the reign of the said King George the Third (31 Geo. III. c. 92), intituled "An Act for abolishing any Act, or Acts, or any restrictions, the Persons therein described from certain Penalties and Disabilities to which Papists or Persons professing the Popish Religion are by Law subject," as entails that no person shall be subject to any case, benefit, or advantage to any person who shall, by preaching, teaching, or writing, deny or gainsay the oath of allegiance, atonement, and declaration herein-before mentioned and appointed to be taken as aforesaid, or the declarations or oaths therein contained, or any of them.

Also so much of the said last-mentioned act (s. 15) as provides and enacts, 'that no schoolmaster professing the Roman Catholic religion shall receive into his school for education the child of any Protestant father.' [Law, Criminal, P. C. S., p. 180.]

Also so much of the said last-mentioned act (s. 16) as provides and enacts, 'that no person professing the Roman Catholic religion shall be permitted to keep a school for the education of youth until his or her name and description as a Roman Catholic schoolmaster or schoolmistress shall have been recorded at the quarter or general session of the peace for the county or other division or place where such school shall be situate, by the clerk of the peace of the said court, who shall be required to record such name and description according to any demand by such person, and to give a certificate thereof to such person as shall at any time demand the same, and no person offending in the premises shall receive any benefit or advantage.'

Also so much of an act of the parliament of Ireland passed in the thirty-third year of the reign of the said King George the Third (33 Geo. III. c. 21, s. 14 [1]), intituled "An Act for the Relief of His Majesty's Papists or Roman Catholic Subjects of Ireland," as provides that no Papists or Roman Catholic, or person professing the Roman Catholic or Popish religion, shall take any benefit by or under this act, unless he shall have first taken and subscribed the oath and declaration herein contained, and shall have been appointed by the said act passed in the thirteenth and fourteenth years of his majesty's reign, intituled 'An Act to enable His Majesty's Subjects, of whatever Persuasion, to testify their Allegiance and submission to his Crown, by appearing before the Four Courts in Dublin, or at the General Sessions of the Peace, or at any Adjournment thereof, to be held for the County, City, or Borough wherein such Papist or Roman Catholic, or Person professing the Roman Catholic or Popish Religion, doth inhabit or dwell, or before the going Judges or Judges of Assize in the County wherein such Papist or Roman Catholic, or person professing the Roman Catholic or Popish Religion, doth inhabit and dwell, in open Court.'

Also an act passed in the said thirty-third year of the reign of the said King George the Third (33 Geo. III. c. 44), intituled 'An Act for requiring a certain Form of Oath of Abjuration and Declaration from His Majesty's Subjects professing the Roman Catholic Religion in that Part of Great Britain called Scotland.'

II. And be it enacted, that from and after the commencement of this act her majesty's subjects professing the Jewish religion, in respect to their schools, places for religious worship, education, and charitable purposes, and the property and service of the burial ground allotted to their use, shall enjoy the same footing as the subjects of the Church of England are subject to, and not further or otherwise. [This section makes a considerable change by placing Jews on the footing of the Established Church, and making them dissenters; and it will enable any person to leave a legacy for the instruction of Jews in their religion, which up to this passing of this act could not be done.] (Jews, P. C., p. 128.)

III. Provided, that nothing in this act contained shall affect any action or suit actually pending or commenced, or any property now in litigation, discussion, or dispute, in any of her majesty's courts of law or equity.

IV. That from and after the commencement of this act all laws now in force against the wilfully and maliciously or contumaciously disquieting or disturbing any meeting, assembly, or congregation of persons assembled for religious worship, permitted or authorized by any former act or acts of parliament, or the disturbing, molesting, or misusing any preacher, teacher, or person officiating at such meeting, assembly, or congregation, or any person or persons, and that all subscriptions shall apply respectively to all meetings, assemblies, or congregations whatsoever of persons lawfully assembled for religious worship, and the preachers, teachers, or persons officiating at such last-mentioned meetings, assemblies, or congregations, and the persons there assembled.

ROMAN EMPIRE, EASTERN DIVISION OF—frequently designated the EASTERN EMPIRE, OORRKA EMPIRE, OR EASTERN EMPIRE, is the Eastern Division of the Roman Empire into two parts occurred at an earlier period than the epoch usually fixed, viz. the death of Theodosius the Great; and was the result of causes which had been long in action. The warlike pre-emience of Italy had enabled the Romans to achieve the conquest of the various and distant provinces which constituted the Roman empire, and the vigour of their central government, and the practical wisdom which usually guided it, enabled them to consolidate these provinces under an efficient control. The reality and unity of the Roman government for the first three centuries of the empire, form a remarkable contrast to the disorderly independence of the Greek states of the Persian empire; and its permanence contrasts in an equally striking degree with the immediate dissolution of the Macedonian empire, consequent upon the death of Alexander the Great. Divisions and civil wars did indeed occasionally agitate the Roman empire during the period mentioned, but they did not arise from attempts at separation or local independence, but from competition for the possession of the whole. Dissimulation was not thought.
capital of the empire. Had the empire, however, been as-
sailed by any one hostile power capable of affecting the safety of
the whole, a sense of the common danger might have sup-
plied a motive of some decision, but every trait had its peculiar
enemies to contend with, and apprehended little injury from
those who assailed the other portions of the empire. The
Germanic confederations of the Aleman and Franks [Ale-
man, p. C.], and the Saxons and Angles of the upper
Danubian frontiers, but neither Greece, Syria, Egypt,
or nor even the lower Danubian provinces were endangered by
them: the Goths [Goth, p. C.] might overrun Maso-
und and Sirmium in the upper Adriatic side of the
Hellespont; while the revived Persian kingdom, under
the dynasty of the Sassanides [Sassanid, p. C.], which
threatened the subjugation of the East, was little regarded in
it. This mutual independence of the se-
ailing nations tended to promote the dissolution of the em-
pire by fixing the attention of its several parts on the enemies
immediately opposed to them and allowed neither leisure to
attend to nor sympathy to feel for others.

The direction in which the fracture was likely to take
place was indicated by the geographical and other circum-
stances of the empire. The principal extension of the empire
was from east to west: and the Romans were not enough of
a naval people to avail themselves fully of the facilities which
the Mediterranean Sea afforded for keeping up the connec-
tion between parts of it. The maritime communica-
tions were maintained by land, except where this was
impracticable, rather than by water. Had the Helles-
pont and the Bosporus been wider, the separation would per-
haps have been made there; but the narrowness of those
straits, and the maritime tendencies of the adjacent Greek
population, so closely united the opposite shores, that the sepa-
ration of the European and Asiatic continents was of little
practical moment; and the place of the fracture was deter-
mited to that part of the empire where the communication by
land, narrowed between the shores of the Adriatic and the
nearest part of the Danubian frontier, was impeded by the
difficulties of traversing the Haemus and the Ilyrian
offshoots of the great Alpine mountain system. South of the Mediterranean, the
place of fracture was determined by the great Libyan desert west of Egypt and of Cyrenaica.

Another circumstance which tended to determine the point
of separation was difference of language. Before the Roman
army had crossed the Adriatic the Greek language had become
the language of literature and education in the countries to
the east of that sea, and formed an important bond of union.
The native languages of the East remained in use as spoken
languages, and after the diffusion of Christianity some of them
(e. g. the Syriac and Coptic and Armenian) came into use again as
written languages; but the infatuation of a large extent of the
sacred literature of Asia Minor, Syria, and Egypt was
Greek. West of the Adriatic the Latin tongue acquired a
similar or even a greater supremacy; for it superseded, though
proportionately in a different form, the Greek, andSpain and Italy in popular use, as well as for literary
purposes, and forms the basis of the modern languages of those
countries.

Had the African provinces west of the Libyan desert posses-
sed the warlike resources of the other parts of the empire
it is not unlikely that they would have formed a separate
portion, and thus have led to a threefold division. But neither
did their internal resources allow this, nor was the frontier of the Atlas pressed by any foe so formidable as to require the
presence of an emperor in that part. The Moorish tribes of
the desert, however formidable as marauders, were impotent for
conquering the temper of the provincial governors, e. g. Julius in the time of Diocletian, and Firmus and Her-
cilian in the reign of Honorius, to acquire independence in
Africa were soon put down: and the African provinces, until
their conquest by the Vandals, remained in subjection, except
during a few brief intervals, to the sovereigns of the
West.

(a. D. 288.) The first emperor of the Eastern part of the empire, who ascended the throne in the West, was Diocletian, who,

on appointing Maximian as his colleague, retained to himself
the government of the Eastern portion, which he held till his
abdication, a. D. 305. [Diocletianus, Caius Valerius, p. C.; Claudio-
Marcius Valerius, p. C.] (303.) Valerius Maximus Galerius, usually known as
Galerius, who had, under Diocletian, governed the
Danubian Provinces, with the subordinate rank of Caesar,
succeeded that prince as Augustus or Emperor in the East,

(311.) Flavius Valerius Licinius and Maximinus Dara
succeeded Galerius. Maximian, who was nephew of
that emperor, or was otherwise related to him, was appointed
Caesar shortly after the abdication of Diocletian. Licinius was
appointed Augustus by Galerius, apparently without passing
through the intermediate stage of being Master of the
Horse, but received the title at the same time as Galerius.
Maximian, offended at the elevation of another to a rank superior
to himself, assumed the title of Augustus also. Both however
appear to have professed a sort of reverence to Galerius during his
life. After his death they divided the East be-
 tween them, Maximian having the Asiatic provinces, and
Licinius the European. The West was meanwhile (a. D. 312)
inundated under the sole dominion of Constantine. In a. D. 313
Licinius and Maximin quarrelled; and the latter, after being
defeated by his rival, poisoned himself at Thessalonica. In a. D. 315
war broke out between Licinius, now sole Emperor of
the East, and Constantine, which ended in the defeat of the
former, who ced ed nearly the whole of his European provinces to the
conqueror. After an interval of eight years, war was
resumed between them; and the defeat and capture of Li-
cinius (a. D. 332) reunited the empire under Constantine.
[Maximinus Dara, p. C.; Constantinus, Flavius Valerius, p. C.]

Family of Constantine

(323.) Constantius was a distant relative who reigned till his
deth, a. D. 337. [Constantinus, Flavius Valerius, p. C.]

From him succeeding emperors seem to have taken in almost
every case the name of Flavius.

(357.) In the division of the dominions of Constantine the Great among his three sons, Con-
stantius, the second son, had the East. He is known as
Constantius II., his grandfather, who was emperor of the
[Magnentius, p. C.], the whole empire was reunited under
Constantius II., who died a. D. 361. [Constantius II., Flavius Valerius, p. C.] (361.) Julianus, Flavius Claudius, commonly known as
Julian the Apostate, nephew of Constantine the Great
by his half-brother Constantius, ruled the whole empire for
two years after Constantius. [Julianus, Flavius Claudius, p. C.]
With Julian the family of Constantine ends.

(363.) Jovianus held the whole empire only three months.
[Jovianus, Flavius Valerius, p. C.]

Family of Valentinian.

(364.) Valentinianus I., almost immediately on his ap-
pointment to the empire, resigned the east to his brother
Valerius. [Valentinianus I., Flavius Valerius, p. C.]

(364.) Theodosius I., emperor of the
West, died in the
Gothic War, a. D. 376. [Valens, Flavius Valerius, p. C.]

(378.) Gratianus, son of Valentinian I., succeeded
Valens in the East, but almost immediately resigned it to
his brother Theodosius, the emperor of the West,
which he had held before from his father's death in a. D. 375. [Gratianus, Flavius Valerius, p. C.]

Theodorian Family.

(379.) Theodosius I., the Great, ruled the East during the
remainder of his life, during the last year of which he
acquired the West also, thus for the last time uniting
the whole empire under one supreme ruler. [Theodosius I.,
Flavius Valerius, p. C.]

(395.) Arcadius, the elder son of Theodosius, suc-
ceded his father in the East, and Honorisus, the younger son,
in the West. [Arcadius, p. C.]

(408.) Theodosius II., for the younger son of Arcadius,
succeeded his father while yet in his childhood. He died
a. D. 450. His government was principally directed by his
sister Pulcheria and his wife Eudokia. [Theodosius II.,
Pulcheria, daughter of Arcadius, p. C.] (450.) Pulcheria, daughter of Arcadius, succeeded her
brother Theodosius: she had devoted herself to a life of reli-
gious celibacy, but upon her brother's death she chose as her
associate in the empire Macrianus, a Theriac, whose merit had
raised him from a humble station to high rank. She married
him under an agreement that he should remain a virgin. She
died before her husband.

[a. D. 450.] (450.) Macrianus Valerius may be classed with the Theodosian
family, his connection with which raised him to the
empire. [Macrianus, p. C.]
He died a. D. 457.

The history of the East during the eventful period (about
170 years) from the first division of the empire under Dio-

(450.) Macrianus Valerius may be classed with the Theodosian
family, his connection with which raised him to the
empire. [Macrianus, p. C.]
He died a. D. 457.

The history of the East during the eventful period (about
170 years) from the first division of the empire under Dio-

(a. D. 288.) The first emperor of the Eastern part of the empire, who ascended the throne in the West, was Diocletian, who,

on appointing Maximian as his colleague, retained to himself
the government of the Eastern portion, which he held till his
abdication, a. D. 305. [Diocletianus, Caius Valerius, p. C.; Claudio-
Marcius Valerius, p. C.] (303.) Valerius Maximus Galerius, usually known as
Galerius, who had, under Diocletian, governed the
Danubian Provinces, with the subordinate rank of Caesar,
succeeded that prince as Augustus or Emperor in the East,
Basiliscus, who occupied Constantineople nearly two years. He fell at last into the hands of Zeno, A.D. 477, and was sentenced to death, A.D. 477 or 478.  

(467.) Basiliscus, who occupied Constantineople nearly two years. He fell at last into the hands of Zeno, A.D. 477, and was sentenced to death, A.D. 477 or 478.  

(468.) Anastasius I., surmounted Silentiarius, from his being one of the ablest of the Sclerotic clergy. He reigned for the right of Constantine and the preceding Auguste, we have as contemporaries Lactantius [LACTANTIUS, P.C.], or the author, who ever he was, of the book De Mortibus Persecutorum [DE MORTUOS PERSECUTORUM, P.C.]; Epiphanius [EPHESIUS PAMPHILE, P.C.]. The Ecclesiastical History of the latter writer furnishes some notices of such events as are connected with the Christian Church before the reign of Constantine the Great. Eutropius [EUTROPIUS, P.C.] is a valuable contemporary authority for the period (a.d. 383-387) included in the extant portion of his history. Aurelius Victor in his De Caesaribus, and the others' authors, give us the details of this reign, [AURELIUS VICTOR, P.C.], giving an abridgment of the history both of East and West; the De Caesaribus comes down to the reign of Constantius II., and the Epitome to the time of Theodosius the Great. Eutropius [EUTROPIUS, P.C.] in his Historia Romana comes down to the accession of Valens, at whose command he wrote, and Orosius in his History to the reign of Honorius [OROSIUS PAULUS, P.C.]. But these writers are brief, and relate chiefly to the affairs of the West. This is also the case with the more copious and valuable work of Olympiodorus [OLYMPIDOROS, P.C.], which is known to us only by the abridgment and extracts given by Flloitus (Floietus) (HISTORIAE ECCLESIAE, P.C.) of a work of compound extent only to a.d. 409. [ZOSIMUS, P.C. Nor of the affairs of the East are we to be gleaned from the Western Chroniclers, Marcellinus, Prosper of Aquitaine, Prosper Tyro, and Victor of Tunes; from the writings of the Emperor Julian, and of the Christian fathers Athanasius, Gregory Nazianzen, and Chrysostom. [ATHANASIUS, ST. P. C.; CHRYSOSTOM, ST. JOHN, P.C.; GREGORY OF NIZIANZEN, P.C.] Of the later Byzantine writers [BYZANTINE HISTORIANS, P.C.], there are several whose Chronicles or Histories include this period; the most valuable are Theophanes' Chronographia and Zonaras in his História enigmaticale, and Costambaris, and the versifying chroniclers Constantine Manasses and Ephraemus, are of less value; the Chronicon Paschale or Alexandrian Chronicle, though meagre, is of more value. Ecclesiastical History, after the time at which Eutropius closes his history, was written by Socrates [SOCRATES, P.C.S.C.]; Sozomen, and Theodoret [SOZOMENOS, P.C.; THEODORETUS, P.C.], whose works extend from the time of Constantine to that of Theodosius II.; and by Eunapius [EUNAPIUS, P.C.], whose work, designed as a sequel to those of the three writers just mentioned, comes down near to the close of the sixth century. These histories are valuable, not only from the importance of ecclesiastical affairs, but also on account of their frequent notice of secular events. The history of the whole period is contained in the Fall of the Roman Empire by Sienonio, in Lardner's Cyclopedia; and in the great work of Gibbon [GIBBON, S.C.], in his History of the Decline and Fall of the Roman Empire, in the Histoire des Empereurs de Tilmann [TILMANN, SIB. LE NEVE DE, P.C.], who has carefully collected almost everything that has been recorded, and has examined and digested it with critical accuracy and generally sound judgment. The copious but wearisome Histoire du Bas Empire of Le Blanc embraces the period subsequent to the death of Constantius Gallus and the accession of Constantine the Great to the rank and authority of Cæsar. To these works we may add the Historia Byzantina of Ducas.  

(457.) Leo I., called the Thracian (D.GREGORIO), Magnus the Great (OGREGORIO), and Macellus (MCLULLAS), the Butcher, was, like his predecessor Marcellus, a Thracian of obscure family. He reigned seventeen years. [LEO I., P.C.]  

(458.) Leo II., grandson of Leo I., by his daughter Ariadne, came to the throne at the age of four years, and reigned less than a year. [LEO II., P.C.]  

(459.) Zeno, called Isaacus, an Isaurian, who had married Ariadne, daughter of Leo I., was slain by the order of Zeno, A.D. 477, succeeded on the death of the latter. His reign, which was troubled by successive rebellions, is described elsewhere. [ZENO, P.C.] He was for a short time expelled from his throne.  

(460.) Anastasius I., surmounted Silentiarius, from his being one of the ablest of the Sclerotic clergy. He reigned for the right of Diocletian in Epirus, ascended the throne on Zeno's death, by the help of the dowager Empress Ariadne, whom he afterwards married. [ANASTASIUS I., P.C.] His long reign was remarkable for the prosperity and the greatness of the empire, and the peace and the happiness of the nation, and the dimensions of the church as that of Zeno had been by rebellion. With Anastasius ends the dynasty of Leo I., with which indeed both Zeno and Anastasius can only be classed by virtue of their marriage with Ariadne.  

(Family of Justin.  

(518.) Justinus, a Dacian peasant who had risen to be general of the eastern army, succeeded to the government and reigned nine years, when he abdicated the throne, and died soon after. [JUSTINUS I., P.C.]  

(527.) Justinianus I. was nephew by his mother Vigiltiata to Justinus I., succeeded to the throne, but, worn down and disabled by illness, he resigned the exercise of sovereignty a.d. 574 to Tiberius, who was created Cæsar; but Justin retained the title of Augustus until his death a.d. 578. [JUSTINIANUS I., P.C.]  

(565.) Justinianus II. left his brother Vigiltiata to Justinus I., succeeded to the throne, but, worn down and disabled by illness, he resigned the exercise of sovereignty a.d. 574 to Tiberius, who was created Cæsar; but Justin retained the title of Augustus until his death a.d. 578. [JUSTINIANUS I., P.C.]  

The dynasty of Justin I. ends with Justin II.  

(578.) Tiberius II., or more fully Flavius Constantinus Tiberius Amphilochius Turbars, wielded the sovereignty with the title of Cæsar from a.d. 574, and received the title and authority of Augustus just before the death of Justin II., from which latter period he reigned four years. [TIBERIUS II., P.C.]  

(592.) Mauritius of Mauritius, had been created Cæsar by Tiberius II., whose daughter Constantia he had married. The reign of Mauritius was chiefly marked by wars and negotiations with Persia. Having become unpopular, he was murdered, with most of his family, by the centurion Phocas. [PHOCA, P.C.], who headed a revolt of the army in Thrace [PHOCA, P.C.], murdered Mauricius, and succeeded to the throne. This bloody tyrant occupied the throne till he was deposed and put to death by Herulfius, a.d. 610.  

From the time of Diocletian to that of Justin I. the limits of the Eastern empire underwent little alteration except by the acquisition of Northern Mesopotamia and of five provinces east of the Tigris, in the reign of Diocletian, and by the cession of these acquisitions by Justinian after the death of Julian the Apostate. Part of the Greater Armenia was annexed to the empire by Theodosius the Great; the Eastern empire was indeed repeatedly invaded; and the Goths in the time of Valens, and the Bulgarians in the reign of Anastasius, had nearly overthrown it. The eastern frontier was almost continually exposed to the hostilities of Persia. Empress Eudoxia, who died a.d. 477, was the first time of Zeno shook the empire to its centre; but it recovered from these shocks, and the reign of Justinian I. was successful in aggression. The Western empire had been extinguished during the reign of Leo I., and the invasions of Justinian were directed against the provinces of the West, which different nations of barbarians had occupied. Africa and apparently Mauretania, and even a small part of Spain, were recovered from the Visigoths by Belisarius, and preserved by the Vandals; and Sicily, with Sardinia, Corsica, and Sardinia, were conquered by Belisarius and Narses. The northern part of Italy and the inland parts as far south as Beneventum were indeed soon lost to the empire by the Lombards, but the kingdom of June the Lombards [LONGOBARDS, P.C.], who gradually extended their encroachments; and the African conquests of Belisarius were in the latter part of the Byzantine emperors; who retained a footing in Italy and Sicily (though their possessions were continually disputed by the Latin and the Saracens) almost to the time of the Crusades. The period from Justinian to Heraclius, the period of the Huns to Phocas, was that of the greatest extension of the Eastern empire. The cession of the provinces east of the Tigris in the reign of Justin I. was far more than counterbalanced by the
acquisition of part of Armenia under Teodosius the Great, by the western conquests of Belisarius and Narses, and by the extension of the Byzantine territory by conquest or settlement along the eastern and northern coasts of the Euxine, the progress of which is not easy to trace. Even after the loss of the northern part of Italy, the Eastern empire was larger than it had been under the emperors who preceded Justinian.

The principal historical authorities for the period from Leo the Thracian to Phocas are Theophanes, Isaccius, Zonaras, the Patriarch John of Smolensk, Malalas or Malalas, Michael Glynas, Joel, and the versifiers: these several writers comprehend the whole period, with the exception of Malalas, whose "Chronographia" relates only during the reigns of Justin I and Justin II. The wars of Belisarius are related by Procopius of Caesarea, whose introductory chapters to his "Bellum Vandalicum," "Bellum Goticum," and "Bellum Persicum," contain some important notices of events previous to that time. The Secret History (Historia Arcana) of Procopius relates to the same period. Agathias relates the events of a.d. 553-559. The history of the Emperor Mauricius (Historia Mauricianae) is related by Theophylactus Simocatta; and the reign of Phocas is included in the work of Nicephorus of Constantinople, De Rebus post Mauricium pontificum, and his Historical History of the Chalcedonian Controversy, comes down to the reign of Mauricius, a.d. 594; and that of Nicephorus Callistus, a writer of much later date, to the accession of Iconoclastes. The reign of Iconoclastes, which lasted for three years, was an exact reproduction of the Tlemcens; but the whole period is included in the works of Ducaeus, Gibbon, Smendius, and Le Beau.

Heraclean Dynasty.

(610.) Heraclius, son of the patrician Heraclius, governor of Africa, driven from Phocas and put him to death. His reign was one of the most interesting and eventful in the whole course of Byzantine history; and his character one of the most subject to change. The earlier part of his reign was characterized by brilliant and successful warlike enterprises, by which the empire was saved from impending ruin. The earlier part was characterized by inactivity, and the latter part by sensuality and carelessness. (HERACLIUS, P. C. and P. C. S.) He reigned above thirty years.

(641.) Constantine III., or more fully Flavius Heraclius Constantius, or Novus Constantinus, was the son of Heraclius, his first wife Eudocia Palia. The name of Constantine was given in the hope that he would renew the glory of the great Constantine. He reigned only about three months, being, as was suspected, poisoned by his step-mother Martina, niece and second wife of Heraclius; she being anxious to make her son Heraclonas (who had been, by his father's will, made colleague with Constantine) sole occupant of the throne.

(643.) Heraclonas. The death of Constantine III. excited a revolt against the government of Martina, who ruled in the name of her son; and both she and Heraclonas were compelled by Valentian or, as it was called, and called by him, to crown his son Heraclonas, son of Constantine III., to a share in the empire; and were soon afterwards deposed, imprisoned, mutilated, and sent into exile, where they died.

(647.) Constantius II. (Constantius, son of Constantine the Great, who had ruled the Western empire) was originally named Heraclius. He ascended to the throne in his eleventh year, and reigned for twenty-seven years. During the first few years of this reign the government was virtually in the hands of Valentine; but Constantius, when he attained to manhood, unceasingly exerted himself to extend and consolidate his eastern territories, already much diminished by the progress of the Caliphate, and still further diminished by the extension of that ruinous empire. Arab, P. C., vol. ii. p. 217; they were, however, vain and unfortunate. His eastern territories, already much diminished by the progress of the Caliphate, were still further diminished by the extension of that ruinous empire. Arab, P. C., vol. ii. p. 217; and the destruction of the city of Rome. The murder of his brother Thibaudus by the emperor's order (a.d. 661) made Constantius a prey to the horrors of remorse. He turned over to Constantinople in 662, and was there placed in the house of the empress, where he was placed in prison. When the Emperor Constantius IV. (669.) Pogonatus, or Heraclius, the Braved, eldest son of Constantius II., succeeded his father. He had been left by his father governor of Constantinople a.d. 663; and on the news of the assassination of Constans, and of the revolt of the Gepidæ and the Goths he took the field with a powerful army and defeated the rebel leader with great loss. He was a man of great courage and determination, and he was a man of great courage and determination. He was a man of great courage and determination. He was a man of great courage and determination. He was a man of great courage and determination. He was a man of great courage and determination.
events which he relates. The Monothelite controversy is discussed largely by St. Maximus, one of the Greek fathers. (711.) PHILIPPUS BARADAS succeeded to the now vacant throne. He patronized the Monothelites. His reign was short: he was deposed, blinded and imprisoned, A.D. 718, by Basil, an officer sent by the one of his generals, George Buraphus, who had rebelled in Asia Minor. (713.) ANASTASIUS II. (previously to his accession he was called Aristius) succeeded Basil. He patronized the orthodox faith in opposition to the Monothelites. He was deposed and anathematized A.D. 715 by the troops which he had sent to attack the Saracens in the port of Alexandria. [ANASTASIUS II., P. C.]

(715.) THEODOSIUS III. made some cessions of territory in Thrace to the Bulgarians. He was deposed (A.D. 715) by Leo, one of his officers, who commanded in Asia Minor. [THEODOSIUS III., P. C.]

**Isaurian dynasty.**

(718.) Leo III. Isaurius, the Isaurian, had borne in early life the name of Conon: he was a native of Isauria in Asia Minor, from which circumstance he is known in history as Leo Isaurius, or the Isaurian. [Leo III., P. C.] He died A.D. 741, after a reign of twenty-three years.

(741.) CONSTANTINE V. surnamed Corinthius, because when he was in his infancy he was relieved thereto as an able and energetic prince; but his reign was characterized by varied success in the field, and by the religious troubles aroused by the Iconoclastic controversy. He is charged with employing cruel and remorseless means in his war against the church, and as oppressor of the so-called orthodox party; but the Iconoclasts, whom he favoured, revered him as a saint. The revolt of his brother-in-law Artabas, or Artavasdes, or Artavmentes, who was exiled and deposed, and crowned with him, and was apparently supported by the image-worshipping party, was near proving fatal to him; but in the end (A.D. 743) he recovered Constantinople, which Artavasdes had only occupied for five days; and the emperor Constantine died A.D. 775, and was succeeded by his son Leo. [Leo IV., P. C.]

(775.) Leo IV., surnamed Chazarus, which name he derived from his mother Irene, who was a daughter of the Chazars, a Turkish nation, and who accompanied her husband in the Volga. [TARTARS—CHAZARS, P. C., vol. xxvi. p. 73.] The reign of Leo was short, but was disturbed by the revolt of his brothers, who were exiled, and by hostilities with the Saracens, who were defeated. Leo died A.D. 780. [Leo IV., P. C.]

(780.) CONSTANTINE VI., sometimes called Phrygroceius, or more accurately Phrygogrossetes, which title is however usually appropriated to Constantine VII., son of Leo VI., succeeded his father, while yet a minor, under the guardianship of his mother Irene, an Athenian whose beauty and genius had captivated Leo. Her endeavours to prolong her son's minority were to no purpose; her influence was withering and blinding, if not the death, of Constantine, A.D. 797.

(797.) Irene, widow of Leo IV., succeeded her son. A project is said to have been formed of uniting the Eastern and Western Empires, and of recognizing Emperor Charlemagne. According to Theophanes and Zonaras and Cedrenus, Charlemagne sent ambassadors for the purpose of arranging the marriage, which was defeated by the influence of Anastasius, then powerful at the Byzantine court. The Western writers, while speaking of the embassy, are silent as to the marriage being one of its objects. Irene was deposed A.D. 802, by Nicephorus, one of her officers, who usurped the throne. The Isaurian dynasty ends with her. It occupied the Byzantine throne eighty-four years. During the reign of the Isaurian princes the empire continued to decline. The emperors, with the exception of Basil II. and Constantine V., were able and active, their power was weakened by religious dissensions. A few years after the commencement of his reign Leo had attempted to put an end to the use of images in the churches. But the issue of the quarrel was not decided in the church, and the emperor, which showed up with even greater earnestness by Constantine, convulsed the whole empire. The successive popes and the bulk of the clergy declared in favour of images; the secular power was with them. Thus the Iconoclasm was dealt a fatal blow. The opposition was reawakened in Italy and the adjacent parts of Italy from the Byzantine Empire, which retained only the southern extremity of that country. This formed an adjunct of the province of Sicily, under the title of Sicilia Secunda, 'the Second Sicily,' from which circumstance it has arisen the designation of 'the two Sicilies,' as applied in modern times to the kingdom of Naples. The use of images was restored by the influence of Irene and by the authority of the seventh general or second Nicene Council, A.D. 787.

The authorities for the Isaurian dynasty are the same as for the Heraclean; but Nicephorus of Constantinople does not come lower than the reign of Michael. The history of the Iconoclastic controversy is given in Gibbon (chap. xlii.) and in the various modern ecclesiastical histories. In that published by the Useful Knowledge Society the account will be found in chap. xii.

(802.) NICEPHORUS I. [NICEPHORUS I., P. C.] fell in battle against the Bulgarians after a short and calamitous reign of nearly nine years.

(811.) Stepheius, son of Nicephorus, was mortally wounded in the same battle in which his father fell: but lingered for some months, during which he was deposed, and was succeeded by Michael Rhangabe.

(811.) Michael I., surnamed Rhangabe, had married Procopia, daughter of Nicephorus. His short reign was unfortunate: and being defeated by the Bulgarians and threatened by the revolt of Leo the Armenian, he abdicated the throne A.D. 813.

The **Chronography of Theophanes**, one of the most important authorities in Byzantine history, ends with the reign of Michael Rhangabe.

(820.) Leo V., called Leo V., P. C.), surnamed from the country of his birth ARMENUS, THE ARMEANS, seized the sceptre from the feeble grasp of Michael Rhangabe. He defeated the Bulgarians, who had penetrated to the walls of Constantinople, and reduced to tributary the whole of the empire. He patronized the Iconoclasts, who now gained the ascendant and persecuted the orthodox. After a vigorous and successful reign, he was murdered by the friends of Michael, one of those officers who had condemned to death and was on the point of executing.

**Dynasty of Amorian.**

(820.) Michael II., surnamed Balises or the Tamer, or, from his birth—Thronod, a Turk—of Amorion, was rescued from prison by his friends, and placed on the throne. He also favoured the Iconoclasts. His reign was without event. The Saracens conquered Crete and Sicily, and almost conquered what remained to the Eastern Empire in Italy; and Michael was twice besieged in his capital by one of his own subjects, Thomas, who had rebelled, but whom, by the aid of the Bulgarians, he at length conquered. He died A.D. 889, and was succeeded by his son Theophilus.

(892.) Theophilos, a vigorous and active prince, was continually engaged in war, but with little success. He protected the Iconoclasts and persecuted the orthodox, yet he has escaped the reproach of heresy by the decision of the council. In 829 three Isaurian princes who followed the same course. He died A.D. 842, and was succeeded by his son Michael.

(842.) Michael III., surnamed Eudemos, the Drencher, came to the crown in minority, and was under the care of Theodore, who restored the use of images and finally crushed the Iconoclastic party. During the reign of the absolute Michael war was carried on unfortunately against the Saracens in the neighbourhood of the Caucasus, in Crete, and in Asia Minor; but the Slavonians, who possessed themselves of Greece, were subdued, and the Bulgarians and the Saracens were converted to Christianity; a change which either abated their warlike restlessness, or diminished their hostility to the empire. Michael was assassinated (A.D. 867) by Basilios or Basil I., whom he had raised to be his colleague in the empire. The Amorian dynasty ended with him.

During the reigns of the Amorian princes the decline of the empire continued, and would have been more rapid but for the diminished power and energy of its great rival the Caliphate. (The Caliphs of whom are not been sufficiently studied at an earlier period), Crete, and Sicily were lost; and the remaining Byzantine territories in Italy were nearly lost in the reign of Michael II.; and the activity and value of Theophilos was by the possession of the central parts of Asia Minor: for the regions south of the Taurus appear to have been already subdued. The history of Leo the Armenian and of the Amorian dynasty is continued in the works of Porphyrjus, Lycias, Jo6, Ephracinus and Constantine Manasses; in the *Chronographia* of the anonymous continuator of Theophanes, in the works of Leo Grammaticus and Symeon Magister, in
the Vita Imperatorum Recensiones of Georgius Monacenus, and in the Reges of Genesius: the continuator of Theophanes and the writers subsequently enumerated, all commence their histories with the reign of Leo V., at the point where Theophanes ceases.

Macedonien Dynasty.

(867.) Basilii I. Macedon, or the Macedonian, an extraordinary man, the son of a small landowner in Macedonia or Thessaly (which latter word is used by some among the Bulgarians, by whom in his youth he had been carried captive, to the possession of the Byzantine throne, by becoming the colleague of Michael III., whom he soon after murdered. He subjugated the Avars, a fierce nation, and after a long persecution, had driven into revolt, and recovered a considerable part of Asia Minor and the south of Italy and Sicily from the Saracens, who had conqueror them. He died a.d. 886, and was succeeded by his son Leo. [Basilii the Macedonian, P.C.]

(886.) Leo VI., surnamed Philosophus, the Philosopher, or Sapientes, the Wise, was engaged in wars with the Bulgarians in the north, and in the south with the Arabs, who attempted to recover Sicily; but his wars were on the whole unfortunate. He died a.d. 911, and was succeeded by his son Constantine. He was the author of various works, the chief of which are noticed elsewhere. [Leo VI., P.C.]

(911.) Constantini VII. Porphyrogenitus, or Porphyrogenitus, succeeded his father while yet a child of six years. He had for his first colleague the son of Basil II., next in order of birth to Leo VI. He died after a reign of a year a.d. 912. The next colleague of Constantine was

(919.) Romanus I., surnamed Lecapenus or Lecapenus Basilus, who assumed the title of Emperor a.d. 919, and subsequently raised his three sons, Constantius in a.d. 919, and Stephanus, and Constantius VIII., in a.d. 928, to the title at least of emperors. Romans succeeded his administration of affairs to Basil II. Constantine VII. only the title of emperor, compelling him to pass his time in retirement, in which he became distinguished by his literary and other accomplishments. But in a.d. 944 Constantine, who had been the last successor of his predecessor, was restored to the possession of the imperial power. The triumph of Constantine had been for some time dead (a.d. 931 or perhaps 926), and Stephen and Constantine, the surviving sons of Romans, had just before expelled their father from the throne, and were themselves deposed by the people, who restored Constantine to the actual possession of the sovereignty, which he retained till his death a.d. 959, carrying on war with considerable success against the Arabs, and receiving the submission of the Iberian mountain states. His literary works are of considerable importance [Byzantine Historians, P.C.] and include: 1. The Life of his grandfather Basil the Macedonian, written by his son Constantine in the Chronicles of Theophanes. 2. De Thematibus, a description of the thematic or military provinces of the empire. 3. De Administrando Imperio, 'On the administration of the Empire,' written by order of Romanus, son and successor of Constantine. 'It contains' (says Dr. Plate, in Dr. Smith's Dictionary of Greek and Roman Biography) 'abundance of geographical, historical, ethnographical, and political facts of great importance; and without it our knowledge of the times of the author, and the nations which were either his subjects or his neighbours, would be little more than vagueness, error, or complete darkness.' 4. 5. Two works on military affairs, respectively styled Tactica, 'Tactics,' and Strategica, 'Strategies.' 6. De Ceremoniis Aulae Byzantinae, 'On the Ceremonies of the Byzantine Court,' a detailed account of the observances of royalty and administration at that time. We have also in Constantinian various valuable Collections or compilations, especially that of Deoplogomenon, on the Embassies of the Romans to other nations and of other nations to them; which contains numerous valuable Excerpta from Polybius and other historians of the Colons, or on veterinary medicine and on agriculture. [Geoponika, P.C.]

(950.) Romanus II. [Romanus II., P.C.] distinguished as Junior, the Younger, sometimes as Fiesus, the Boy, reigned only a little over a year a.d. 959. His death a.d. 963 of poison administered to him by his wife Theophane.

(963.) Basilii II. and Constantinos IX., or as some call him (not recognizing the son of Romanus Lecapenus) Constantinos XI. and Basil, the two sons of Romanus II.; but their predilect mother and guardian Theophane married Nicophorus, a valiant and successful general, and raised him, nominally to a share, but actually to the sole possession of the empire.

(963.) Nicophorus II. Phocas exhibited as a sovereign the same military skill and valor which he had previously shown to his new master, Basil II., P.C. He was the first to bring the war of existence to a close by war; in the east he was successful: Cilicia and the north of Syria, with the strong cities of Tarsus, Antioch, and Aleppo, were recovered; and even Mesopotamia was reconquered. The war in Asia Minor was less signal and complete: he could only dispute with the Saracens and with the Western Emperor (Theo) the possession of the southern extremity of Italy and of the island of Sicily. In Africa he was not victorious, but was able to subdue a part of the country. The defeat of Nicophorus made him unpopular, and the infamous Theophano, who was weary of him, conspired with his paramour John Zimisces to assassinate him. He was murdered a.d. 969.

(969.) Ioannes I. Zimisces or Zimisce, surnamed (Theopilos) succeeded to the sovereignty of Nicophorus; and, like him, was distinguished by warlike pre-eminence, both as a subject and as emperor. One of his first acts was to banish the guilty Theophano. A rebellion, raised by Bardas Phocas, was soon suppressed; and John was equally successful against foreign foes. He defeated the Russians, who had nearly conquered Bulgaria; and restored the Bulgarian king to his throne, but in subordination to the empire: he recovered the empire, though only for a short time, its long lost possessions in Mesopotamia, and extended the conquests of his predecessor. But his long and brilliant career was cut short by poison administered by some of his own courtiers, after a reign of only six years.

From a.d. 973 begins the actual reign of Basil II. [Basilis Leucis] who arrived at maturity to exercise the sovereign power, and of his brother Constantine; but the youth of Constantine in the first instance, and afterwards his luxurious indulgence and carelessness, left the government to the able and energetic Basil. A dangerous rebellion by Bardas Sclerus, was with much difficulty suppressed, and the conquest of Byzantine Italy and Sicily by Otho or the Sarracens was prevented by the wise and able chief by the imperial power. Having Christianized the Christianized the Slavonic language and made it a medium of education, and made it a medium of education, and had succeed in the struggle for the possession of those countries. His martial prowess retained the conquests of his predecessors in Syria, despite of the efforts of the adjacent Saracen powers. By the complete overthrow of the Bulgarian king he restored the long lost frontier of the lower Danube, as far up as Sirmium; he defeated the Caucasian mountaineers and protected the empire from invasion and was preparing for the complete conquest of Sicily and Byzantine Italy when he died a.d. 1025. Constantine survived his brother another three years; and his death a.d. 1028 closed the golden age of the Macedonian dynasty (though it continued in the female line still longer), the supremacy of which was of longer duration than that of any other imperial dynasty, except the closing one of the Palaeologi.

The Macedonian period of a hundred and sixty years was one of apparent, if not of real development. The frontiers of the empire had been extended in the north from the defiles of Mount Haemeus to the bank of the Danube, and in the south from the range of the Taurus to the heights of Lebanon and the banks of the Euphrates and even of the Tigris. The throne had been occupied by several warlike princes, and the decay of the rival powers, the Caliphate [Caliphs, P.C.] and the Bulgarian kingdom, rendered their prowess effectual for the revival of Byzantine greatness. The literary taste and achievements of Leo VI. and Constantine VII. conduced much to the revival of literature; and several valuable writers belong to this period. The history of this era is contained in Zonaras [Zonaras, Ioannes, P.C.], Codruses, Glycas, Ephremius, and Constantius Manasses; the anonymous continuator (or continuator) of Theophanes, whom we shall sometimes call, but on insufficient ground, Leoontius, Symeon Magister, Georgius Monachus, Leo Grammaticus, and Genesius. Of these authors Genesius ends with the death of Basil II. a.d. 1025; Leo Codruses, with the death of Romanus I. a.d. 948 or 949, a few years after his deposition; and the continuator and Symeon Magister, with the early history of Basil II. To this time belongs a second part of Jomard [Jomard], who lived in the reign of Basil II., and whose history comprehends the reigns of Romanus I., Nicophorus Phocas, and Ioannes Zimisces (a.d. 969-1078).
Torysh.] Sossidion's Fall of the Roman Empire ends with the tenth century.

[Romans] III. surnamed Argynus or Argyropulos, ascended the throne as the husband of Zoë, one of the daughters of Constantine IX., who also left another daughter, Theodore. Romans, after a short reign, in which his troops were defeated by his brother who, on the death of his father, was assassinated by his wife and her paramour Michael, whom she elevated to the throne. [Romans III., P. C.]

(1054.) Michael IV. Papitchio, the Paphlagonian, reigned meanly and miserably for more than seven years and a half.

(1041.) Michael V. Calaphates or Calaphata, i.e. a governor of vessels, a name derived from the occupation of his father, who was a Basilian and a man of Zob, but the people of Constantinople, inspired with indignation at this punishment inflicted on one of her high birth, insisted on her recall, and on the release of her sister Theodore from the monastery in which she had been placed, and disposed Michael, depriving him of his eyes, after he had reigned little more than a year.

(1042.) Zoë and Theodore reigned jointly for a few months, when Zoë married and raised to partnership in the empire.

(1042.) Constantius X., or as some reckon Constantine IX., surnamed, from his valour, Monomachus, the Single Commander. This emperor had to avenge a revolt in Crete, to which the Qoloiki, a nation of Muslims, had manifested a decided sympathy when they had gone to defend his throne from his rival, Georgius Maniakes, the greatest of the Byzantine warriors of his day, who being driven by injustice to revolt, advanced against Constantinople and laid the capital in ashes; but the empire fell, probably by assassination, in the moment of victory. Another rebel, Leo Tornicius, a relative of the emperor, was defeated by Constantine, who also vanquished a Russian fleet which threatened Constantinople [Romus, P. C.], and extended the limits of the empire in the East by incorporating the territory of a subordinate chieftain of Armenia and Iberia who had revolted and was subdued. Zoë died a.d. 1050 and Constantine a.d. 1054.

Theodora was thus left sole inheritor of the sovereignty. She had previously refused to marry; but toward the close of her short reign, she consented, on her death-bed, to a nominal union with an aged warrior named Michael.

(1056.) Michael VI. Stratelates, thus succeeded to the empire, which he held for about a year, when he was married. Theodora had died a few days after their marriage. The short reign of Michael VI. was troubled by the unsuccessful revolt of Theodolus, a cousin of the late emperor Constantine X.

(1057.) Isaac I. Comnenus, whose successful revolt had deposed Michael VI., obtained the empire, but was soon after induced by his failing health to resign it. The succession was offered first to Joannes Comnenus, the Emperor's brother, who declined it; and then to Constantine Ducas.

(1059.) Constantius I. (or X.), surnamed Ducas reigned seven years, in which the empire was assailed by the Hungarian and other enemies on the side of the Danube. On the description of this part of his reign.

(1062.) Michael VII. surnamed Palaiologos, Andronicus I., and Constantine XII. (or XI.) Porphyrogenitus, or Porphyrogenitus, all minors, succeeded to the nominal possession of the throne, under the guardianship of their mother Eudocia [Eudocia, P. C.], who after a regency of some months conveyed by marriage the actual sovereignty to Romania, the mother of her sons.

(1067.) Romans IV. surnamed Doukas, valiantly opposed the progress of the Turks, who were in force in Asia Minor, but his efforts resulted in his defeat and captivity (a. d. 1071). [Seljukus, P. C.] On his release, he attempted to escape and was taken prisoner, and deprived of his eyes with such cruelty, that he died a few days after. [Romans IV., P. C.] Eudocia had, during his captivity, been confined in prison.

Michael VII. then assumed the exercise of the sovereign power: but by his cowardice he incurred the contempt of his countrymen, and his brother's, and he was succeeded by the rebel Nicophorus Botanoteinos, who succeeded to the throne at the reign of the family of Ducas ended with Michael VII. It occupied the Byzantine throne less than twenty years.

[Romans III. Botanoteinos, P. C.] had to struggle for the throne with a rival, Nicophorus Bryennius, who had revolted against Michael at the same time as his namesake. Alexius Comnenus, the general of Botanoteinos, defeated Bryennius, and compelled him to leave the empire, but shot the deposed emperor on his own account, and succeeded (a. d. 1081) in deposing Botanoteinos and acquiring possession of the throne. He was the nephew of the Emperor Isaac I., and son of that Joannes or John Comnenus who, on the death of his father, had assumed the crown. The accession of Alexius was the commencement of the permanent sway of the Comnenian family or dynasty.

The century and a half which elapsed from the close, at least in the narrow limits of the Macedonian Empire, of the accession of the Comnenian, was a period of disaster and decline. The various domestic revolutions, several of them accompanied by bloody civil wars, have been noticed. In the West, the first visit of the pilgrims, then, on the invitation of a fugitive revoler of the Byzantine city of Bari, as mercenary soldiers, had gradually conquered, between a.d. 1040 and 1080, the Byzantine portions of Italy and Sicily, the last relics of the conquests of Belisarius and the other generals of Justinian. In the East, the Turks, under their sovereigns of the Seljuk dynasty [Seljukus, P. C.; Turgut, Turgu, P. C.], conquered the Caucasian and Armenian provinces of the empire, and either before or very soon after the accession of Alexius, succeeded in establishing in Asia Minor a kingdom of which the capital was fixed at Nicaea, or Nice, in Bithynia, about a hundred miles to the west of Constantinople.

The disasters of the period were augmented by the increasing bitterness and the complete separation of the Greek and Latin churches [Greek Church, P. C.], which weakened the defense of the empire, and the small degree of the Sultan of Egypt and the West of Europe, and led the latter to regard with comparative indifference the threatening progress of revolted Mohametanism under the protection of the Turkish power.

For the history of this period we have to refer to the generals already enumerated; but Cedrenus ends with the year 1058, and Constantine Manasses with a. d. 1081. To these we may add Joannes Skylitzes Comnenus, the fragments of whose history refer to the period from a.d. 1058 to 1078; Nicophorus Bryennius (not the Emperor so called, but the son-in-law of Alexius Comnenus), whose Commentarii give the history of Alexius before his accession to the empire; and Anna Comnena, daughter of Alexius, and wife of this Nicophorus, who has in her Alexius given the history of her father's life.

[Romans III. P. C. Crusades, P. C.]

(1081.) Alexius of Alexius I. Comnenus. The commencement of the long reign of this prince was unfortunate: the Turks pursued their conquests on the east, and the Normans, crossing the Adriatic, invaded the western provinces of the empire. The hostility of the Turks was however repelled, and that of the Normans diverted by the first Crusade; and Alexius, following in the wake of the Crusaders, recovered possession of Asia Minor, with the exception of the islands and mountainous districts. He died a.d. 1118. [Romans I., P. C.; Crusades, P. C.]

(1118.) Joannes II. Comnenus, or as he is commonly termed Galo-Joannes, who reigned ten years, given in detail on account of his diminutive stature and homely features, succeeded his father Alexius. His eminent virtues rendered his reign one of the most truly glorious in the Byzantine annals.

He repelled the hostile attempts of the Hungarians and others on the Danube, and of the Turks in Asia. A vain attempt to dispose of him at the commencement of his reign was made by his accomplished but ambitious sister Anna Comnena and her husband Nicophorus Bryennius. [Anna Comnena, P. C.] Joannes II. died of a wound received while hunting, a.d. 1143, just as he was on the point of attempting to subjugate the Latin States founded by the Crusaders in Syria and Asia Minor, a.d. 1144. [Manuel I. Comnenus bore, in character, a singular resemblance to our own Richard I. He continued the warlike enterprises which his father had made, and against the Turks in Syria and Egypt. His transactions with the Crusaders were very varied. The Latin States were not restored to the Latins, but they were spent in indolence, his wars and luxuries alike exhausted his subjects, and his long struggles merely maintained, without extending, the limits of the empire.]

(1143.) Manuel I. Comnenus bore, in character, a singular resemblance to our own Richard I. He continued the warlike enterprises which his father had made, and against the Turks in Syria and Egypt. His transactions with the Crusaders were very varied. The Latin States were not restored to the Latins, but they were spent in indolence, his wars and luxuries alike exhausted his subjects, and his long struggles merely maintained, without extending, the limits of the empire.

(1180.) Alexius III. Botanioteinos, who had succeeded to the throne on the death of his father Manuel I. He was only ten years of age at his accession, and was under the guardianship of his mother Maria; but both mother and son were, in about three years, put to death by Andronicus, son of Isma Comnenus, who was a younger son of Alexius I.
(1183.) Andronicus I. Comnenus then usurped the throne, but after a reign of two years was murdered by the people of Constantinople. [Andronicus Comnenus, P. C.] In him the male line of the Comneni ends. He was succeeded by Isaac Angelus, whom he had attempted to put to death, and who perished in the populousness against Andronicus.

(1185.) Isaac II. Angelus was descended from the youngest daughter of Alexius I. His contemptible reign was marked with the final loss of the isle of Cyprus, usurped by a rebel, another Comnenus, from whom it was taken by Richard I. of England and given to Guy of Lusignan, the expelled King of Jerusalem; and of the territory between the Haemus and Bupleus, which was lost in the revolt of the Bulgarians and the re-establishment of their kingdom, the princes of which united themselves and their people to the Latin Church. Isaac recovered, however, some parts of the European Albania and Epirus from the Normans of Italy and Sicily. Isaac was dethroned and blinded after a reign of ten years by his own brother, Alexius, who succeeded him.

(1195.) Alexius or Alexius III. Angelus or Comnenus (which latter name he assumed), after an unfortunate reign in which he was defeated by the Turks in Asia Minor and by the Bulgarians and Comanis in Europe, was dethroned by Alexius, son of Isaac II., who was assisted by the Crusaders of the Fourth Crusade.

(1203.) Isaac II., the deposed and blinded emperor, and his son Alexius III. Angelus or IV. Angelus, were, in consequence of this revolution, placed on the throne; but a revolt of the populace, led by Alexius, son of the house of Ducas, led to their deposition and to the murder of Alexius IV., whom Isaac II. soon followed to the grave. The branch family of the Angeli, and indeed the dynasty of the Comneni, ended with the death of Isaac II.

(1204.) Alexius of Alexius V. Ducas, surnamed Murzoukides, i.e., of the Shaggy Eyebrows, the successful rebel, succeeded to the throne (which a shadow of an emperor, Coloman Alexius, and not an instant occupant), but was at once besieged, and after a few months taken prisoner and put to death by the Crusaders, who captured Constantinople, divided a considerable part of the conquered territory into principalities, and established a line of Latin princes on the throne of the Eastern Empire. [Baldwin I. Emperor of Constantinople, P. C.; Danilo, Enrique, P. C.]

The period from the accession of Alexius I. to the capture of Constantinople by the Latins is one of great vicissitude. Alexius I. found the empire reduced in limits and exhausted in resources; but his dexterity in availing himself of the results of the first crusade, and the abilities and valor of his successors Johnnies II. and Manuel I. extended the limits without perhaps materially increasing the strength of the empire. From the death of Manuel we have a period of rapid career, occupied in the conquest of Nicæa, the Seljuk Turks losing a considerable part of what they had lost in Asia Minor: until the empire was limited to Thrace, Macedonia, Epirus, Greece, i.e., its islands (of which, however, Constantinople was lost by the Greeks in 1264, and emperor of a portion of Asia Minor, especially on the coast. Of this diminished territory a considerable part fell with the capital to the hands of the Latins. Of that part which escaped their power, the eastern coast of the Euxine was appropriated to form the new Greek empire of Trebizond or 'Anatoilia (Trebizond, Empire of, P. C.); and two other fragments were detached to form the despotates of Epirus and Thessaly, the former of which, though sometimes tributary to the Eastern Empire, was never again incorporated with it. [Albania, P. C.] The remainder of the independent empire of the Greeks was the republic of Venice, which assumed the imperial title, fixed the seat of their government at Naos or Nicæa, in Asia Minor, and afterward recovered Constantinople, will be regarded as the connecting link between the two great states, of which the former was the capital, and the latter the capital of the new Greek empire. These states were formed by the Greeks almost immediately after the fall of Constantinople. The history of Alexius I. is contained in Zoparas and Glycas; but especially valuable is his Anabasis, and the shorter work of Joel, in the Monocentric Chronicle of Ephraeminis, which becomes from his reign now more full and important; and especially in the Alexios of his daughter Anna Comnenus, P. C. The history of the subsequent period is narrated by Ephraeminis and Joel, of whom the latter ends with a.d. 1204; and in the histories of Cinnamus, which compreends the reign of Johnnies II. and nearly the whole of that of Manuel I., and of Niceives Comnenus, and Niceives Choniates, which extends from the death of Alexius I. to the death of Baldwin I., first Latin emperor, a.d. 1206. The Latins authorities, Guilielmus Tyrannides (William of Tyre), and the other continenetals, of which the Per Franciscus of Comnenus, and Bonogon and others not of that collection, are enumerated in Michaud's Bibliographie des Croisades. [Crusades, P. C.]

(1204.) Baldwin I. Baldwin I., P. C., Count of Flanders and Hainault, was appointed emperor by the victorious crusaders; but was, after a year's reign, captured in Thrace and the Bulgarians and the Boherns, and the Bulgarians their allies, and died in captivity.

(1206.) Enrique or Henry, surnamed andreanensis, of Amoq, brother of Baldwin I., succeeded him. He died after a reign of incessant warfare a.d. 1216.

(1216.) Peter de Courtenay, Peter of Courtenay, Count of Acre, ascended the throne in conjunction with and in the right of his wife Isabele of Yolande, sister of Baldwin and Henry. He never reigned in Constantinople, but was taken prisoner on his way thither by the despot of Epirus, and died in captivity a.d. 1219. Yolande died soon after.

(1219, or, according to others, 1221.) Robert, or Robert, Count of Courtenay, succeeded Peter of Courtenay, and succeeded to the throne. He was, some time after, expelled by his own subjects, and died a.d. 1228.

(1228.) Baldwin II. Baldwin II., Emperor of Constantinople, had in a.d. 1229 taken the city of Yolande, succeeded his brother Robert; but, as he was a minor, John of Brienne (John of Brienne), titular king of Jerusalem, a veteran of nearly four years, was appointed (a.d. 1229) his guardian. John repelled the Nicene Greeks and the Bulgarians, who had besieged Constantinople, and died soon after a.d. 1237. The reign of Baldwin in Constantinople lasted till a.d. 1261, when the city was surrinded by the Mohammedans. Baldwin escaped and survived the event about fourteen years. The principal western historian of this transient Latin empire is Villhardouin, one of the leaders in the capture of Constantinople.

The Greek writers will be noticed when speaking of the authorities for the contemporary Greek emperors of Nice.

Greek Emperors of Nicea or Nice.

(1204.) Theodoreus II. Lascaris (Theodoreus Lascaris, P. C.), in an active reign of eighteen years, re-established the Eastern Empire in a portion of its ancient Asiatic territory, of which Nicea was made the capital. He had married Anna, daughter of Alexius III. Angelus or Comnenus.

(1222.) Joaniss III. Ducas Vatatzes succeeded Theodoreus Lascaris by virtue of his marriage with Irene, daughter of Theodore Lascaris, or rather by his merit, which induced the Latins to accept him as a brother. His prudence and valour gradually extended his dominion, until he had recovered nearly all that the Latins had conquered in Asia and Thrace, except Constantinople itself. He crushed the Latins in the Grecian war (a.d. 1244), and drove the Nicene Greeks out of Asia Minor, and recovered a portion of territory from the Greek empire of Trebizond. He died a.d. 1255.

(1255.) Theodoreus II. Lascaris, son of John III., succeeded his father, and died after a reign of four years.

(1259.) Ioannes IV. Lascaris, a minor, son of Theodore II., succeeded, but he was soon virtually and afterwards openly deposed, and then blinded by Michael Palaeologus, first emperor of the family of the Palaeologus, and first of the restored Greek emperors of Constantinople.

The historians of this period are Georgius Acropolites; whose history has not comprehended the period when the sense of the empire was at Nicea (a.d. 1204-1291); Nicephorus Gregoras, whose history begins at the same point but comes down later than that of Acropolites; and the Metrical Chronicle of Ephraeminis, which begins in the year 1261. The history of Nicecis Choniates comprehends only a year or two after the capture of Constantinople by the Latins.

Restoration of the Sept of the Eastern or Greek Empire to Constantinople.

Family of the Palaeologus.

(1290.) Michael VIII., Palaeologus, or more fully Palaeologus, Michael Palaeologus, of Alexius III., ascended the throne as the colgte of the boy Emperor Ioannes IV. In 1261 Constantinople was recaptured by Alexius Stratelates, and Michael restored the
seat of government to that city. But if the Latins were ex- 
expelled, the empire never recovered the extent which it had 
before the Latin conquest, and had been dismembered on the 
west and east by the empire of Trebizond and the despotic 
of Epirus; though the despot of Epirus had, in the reign of 
Joannes V, been driven from power. It also lost many parts 
under the late Latin principalities remained in Greece, 
notably the Duchy of Athens, which continued till the 
time of Manuel II. [ATHENS, P. C., vol. iii. p. 19.] The im-
portance of Palaeologus, to the extent of which many noted 
parties in the state were finally separated from the empire by the Venetians or other western 
powers: Cyprus had been previously lost in the reign of 
the weak Isaac II. Lesbos, Chios, and Rhodes were however 
recovered by the Latins, when the Venetians, who had 
encouraged the Venetians, Pisans, and other Latins engaged 
in commerce or manufactures to remain at Constantinople, 
or in the suburbs, and established a Genoese colony in the 
sewer. Its guild in binding and healing the 
unhappy colleague Joannes was punished by Arsenius, 
patriarch of Constantinople, with excommunication; and 
the retaliatory measure of the deposition of Arsenius led 
to serious schism in the church of nearly fifty years' duration. 
A hyperclical union with the Latin church, ratified at the 
Council of Lyon, a.d. 1274, augmented the religious troubles of the Greeks, though it averted the threatened attempts to re-
establish the Latin throne of Constantinople. Michael died 
a.d. 1283.

(1283.) ANDRONICUS III. PALAEOLOGUS, or more fully 
DUCS COMMERVS ANGELVS PALAEOLOGUS, distinguished as 
the Younger, succeeded his father Michael VIII. and reversing the policy 
which Michael had pursued, dissolved the hollow solid of the churches and was excommunicated by the Pope (a.d. 1207.) His reign is marked by the establishment in Asia Minor (about a.d. 1300) of the rising monarchy of the 
Osmans, or Ottoman Turks, so called from Osman their founder, in place of the declining kingdom of the Seljuks, which had been left in Constantinople by the Crusaders. A native of Persia, the descendants of Zenghis or Genghis Khan. [TURKEY, TURKS, P. C., vol. xvi. p. 365.] The devastations of the remaining Asiatic provinces of the 
Eastern Empire by the Ottomans was repelled by some 
Catalan and other mercenaries under Roger de Flor, whose 
assassination, under order of Andronicus, in consequence of the disasters occasioned by him and his men, led to intestine war, 
which was at length ended by the retreat and establishment 
of the Catalans in the Duchy of Athens. The closing years of 
the reign of Andronicus were clouded by another intestine 
war or succession of wars between himself and his grandson 
and colleague Andronicus III. (a.d. 1292-1328), who obliged 
the old emperor to abdicate. Andronicus died four years after 
his abdication (a.d. 1329.)

(1329.) ANDRONICUS III. PALAELOGUS, or more fully 
DUCS COMMERVS ANGELVS PALAELOGUS, distinguished as 
the Younger, succeeded on the abdication of his grandfather. 
He was defeated by the Catalans of Athens, and by the Turks, 
who captured the city in 1347, and restored it to the empire. 
In Asia Minor, Rhodes, after a short period of virtual inde-
pendence, had been occupied by the Knights of St. John of 
Jerusalem [HOMPHALLER, P. C., in the reign of Andronicus 
the Elder. Andronicus III. died a.d. 1341.

(1341.) JOANNE VII. PALAELOGUS, called by some 
JOANNE PALAELOGUS I., and (1342) JOANNE VI. CANT-
ASCHEUS, or more fully ANGELOUS COMMERVS PALAE-
LOGUS CANTASCHEUS, and so called, was the son of his monarch, 
by whom his father's name is pronounced; and was 
ascertainment of his power and his condemnation to death drove him to rebellion, and 
he was crowned as Andronicus a.d. 1342. A civil war, in which 
the empire was divided between the two sons of the late 
empire of Andronicus III. The overthrow of Cantacuzenus's power 
and his death was occasioned by the.PNG

(1355), and his retirement to a monastery, where he 
employed himself in writing a history of his own time from 
a.d. 1321 to 1387) and where he died. From the abdication 
of Andronicus III the empire began the actual reign of Joannes Palaeologus, which was marked by the extension of the power of the Turks in Europe, and their capture of Adrianople (a.d. 1361), which they made their capital. They first gained a permanent footing on the European side of the Dardanelles in a.d. 1354, during the second civil war between Cantacuzenus, by capturing the castle of Tymbre, now Chini or Jemene, 
by the Egyptians, and near Gallipoli. [TURKEY, TURKS, P. C., vol. xvi. p. 365.] Andronicus died a.d. 1391, and his empire was divided among his son Palaeologus, the immediately adjacent parts of Thrace, and 
and some parts of Macedonia, Northern Greece, and the 
Mora, hastened into the west to solicit aid from the Pope and 
the west to obtain which he had to the Roman Church; but he not only failed in his purpose, and was arrested for debt at Venice. Released by the interve-
nestion of his son Manuel, despots of Thessalonica, he returned 
home, where he had to suppress a revolt of his son, Andronicus (a.d. 1385), who was taken prisoner and condemned to lose his sight. The operation of blinding was not effectually 
performed, and Andronicus escaped and imprisoned father, 
but was obliged to release him. He obtained, however, the 
cession of a portion of Thrace, which was formed into the 
principality of Selymbria. Joannes Palaeologus died, 
after an unhappy reign, in a.d. 1390 or 1391.

(1391.) MANUEL II. PALAELOGUS, who succeeded his father, 
Joannes V., during whose life he had shared both the name 
and exercise of sovereignty. He was attacked by the Turks, 
and by his brother Andronicus, prince of Selymbria; but made a 
peace with them in 1391, for which he was left in Constantinople, if not co-emperor; and visited Italy, France, England, and Germany (a.d. 1400-1402), to solicit aid against the Turks. 
Bajazet, the Turkish sultan [BAJAZET I., P. C.], meanwhile 
threatened the overthrow of Constantinople and the extinction 
of the empire, which was saved rather by the opportune 
abduction of Timour or Tamerlane [TURKISH, P. C.] over 
the Turks at Angora, and the captivity of Bajazet (a.d. 1402), 
than by Latin aid. Manuel was finally obliged to the empire the whole of the Morea. He died a.d. 1425.

(1425.) JOANNE VII., PALAELOGUS, surnamed PAPYRRO-
GENETUS or PAPPYROGENETUS sometimes called JOANNE 
PAPYRROGENETUS I., succeeded his father Manuel, and followed 
the same policy of seeking aid from the west, to conciliate 
which he brought about the hollow union of the Greek and 
Latin churches at the council of Florence, a.d. 1438, 
and to be present at which, he visited Italy. He ruled 
personally in Constantinople: the fragments of the empire in 
the Morea and in the Tauric Chersonnes, the Crimes, were ruled by his brothers as his vassals. His reign precipitated the down-
fall of the empire, for his project of union with the Latin 
church disgusted his subjects; the allies secured by him were defeated by the Turks at Varna a.d. 1444 [MURAT, I., 
P. C.], and the Turks attacked the Morea and allowed its ruler, 
Constantine, the empire's brother-in-law, to shift the 

(1448.) CONSTANTINE XIII. (some call him XII.) PALAE-
LOGUS, succeeded his brother, and a league of the Venetians 
succeeded his brother Joannes VII. He resigned his pos-
sessions in the Morea to his brothers Demetrius and Thomas. 
His brief reign was ended by the capture of Constantinople 
by the Turkish Sultan Mahomet II. a.d. 1453. Constantinople fell bravely in the defence of his capital, and the empire of the 
East fell with him: its dismembered portions were subdued by 
the ambitious and powerful Mahomet a few years after, 
except such as were occupied by the stronger hand of the 
Latins. Demetrius and Thomas Palaeologus were expelled 
from the Morea in or soon after a.d. 1460; the empire of 
Trebizond was extinguished in a.d. 1464, and all the value 
of Scanderbeg [SCANDERBEG, P. C.] was preserved. [SANDERBEG, P. C.], a.d. 1467, did not prevent the final subjugation of Epirus. [MIMOHIT, P. C.]

Thus were extinguished the name and the last remains of the empire. But the events that passed from 1261 to 1453 had it had subsisted for twenty-two centuries; from the settlement of the empire by Augustus nearly fifteen centuries; a duration as yet unmatched in the history of the world, unless it be in China. From the year 476 to 1204 the empire was the first constant line in the history of the world, and its power was by the 
perilous service was hardly interrupted though the seat of empire was temporarily fixed at Nice. The despotic character
of the government, if it prevented the growth of that national spirit and character which really constitute the strength and prosperity of a nation, yet prevented the dissolution of the empire, which presents amid frequent disasters a remarkable cohesiveness and unity, until the Latin conquest in A.D. 1204. But despite the decay of the old character of the empire depended on the personal character of its rulers, its history exhibits alternations of decline and recovery according as the personal worth of one or another of the character of vigor and activity; but each instance of the recovery generally fell short of its predecessors. During the temporary fluctuations of the condition of the empire, the tide of its greatness was gradually rolling back. Theodorich the Great died in possession of the whole extent of the empire both in the east and west. Justinian recovered only a portion of the latter. Heraclius saved the empire from extinction at the hands of the Persians, and effectively crushed their power; but he did not recover what had been taken by the Lombards in the west, and Africa and Palestine, which were wrested from his successors by the Saracens, were never recovered. The revival effected in the Macedonian period by Basil I., Nicephorus, John Tricones, and Basil II., fell short of that of Heraclius; and that of the earlier Comneni fell short of the success of the Macedonian princes. The fall of Lecanis and Messe, never more than a fragment of the empire of the Comneni, grew less and less until its extinction by the Turks. Yet this fragment preserved the name of the Roman Empire, which it has transmitted to the modern imperial state of Solomon in Rum-Illy in Europe, the last seat of the Byzantine Empire (Rom.-It., P. C.), and Rüm or Rumän, in Asia Minor, the seat of the empire of Trebizond. The last and most precious remnant of the empire is contained in the 'Roman History,' or rather 'Romaic History,' of Nicephorus Gregorius (from A.D. 1204 to 1351); in the history of the emperors (from Michael Palaeologus to Andronicus the Elder) of Gregory Panourgus; in the life of the Emperor John Cantacuzenus, containing the account of his own time; in the 'Historia Byzantina' of Ducas, especially including the reigns of the two Emperors, V. and VI., and the period to 1462; in the Chronicles or Annals of Georgius Phrantzes or Phrantz, from the recovery of Constantine in 1261 to A.D. 1477; and in the History of the Turks by Laonicos Chalcocondyles. We do not mention the contemporary Latin historians whose works include notices of Byzantine history; and of modern historians we only mention Ducas, L. Beato, with his continuator Ameibison, and Gibbon. Much valuable information is contained in the articles on the Byzantine Emperors and other eminent personages connected with the Eastern Empire, chiefly written by Dr. Plate in Dr. Smith's Dictionary of Greek and Roman Biography, by Dr. Winckler's Die Geschichte des Romischen Kaiserthums, and with all its admirable qualities, is unsatisfactory as a history of the Eastern Empire. The unity which it has given to his episodes has destroyed that of his main subject; and as he provides for his different parts of his story in the various portions which constitute the history of a reign or period. The empire itself is forgotten while we follow his absorbing narratives of the migrations of the Huns, the conquests of the Saracens or Moslems, and the vicissitudes of the Crusades; and the Byzantine history, interesting and important as it is, is yet to be written in a form suitable for the English reader.

ROMANIELLI, GIOVANNI FRANCESCO, was born at Viterbo in 1617. He studied a short time at Demerichino, but he is chiefly known as the scholar of Pietro da Cortona; and he was one of the principal managers of his works. He was from one of the best families in Rome, and was the son of Carlo Maratta and the school of Sacchi; and even to Pietro Cortona himself. Romanelli's picture of the Deposition, in the church of Sant' Ambrogio della Massa, gave him a temporary name above all his rivals. His picture of Pietro da Cortona to paint a picture for the same church, his San Stefano, which, when it was hung up in its place, so far eclipsed the picture of Romanelli that Bernini himself observed that it was easy to see who was the master and who the scholar. Romanelli showed more deliberation of execution but considerably less power than Cortona. There is a Presentation in the Temple in one of the rooms of the Vatican, and the workmanship, from a picture by Romanelli which is in the church of the Certosa. He was twice in Paris with his patron Cardinal Barberini, and he died at Viterbo in 1683, when about to set out with his family upon a third visit to that capital. There is a large copy of Guido's Triumph of Bacchus at Hampton-Court, by Romanelli. (Pascoli, Vie de Pittores sc. Moderni; Lancisi, Storia Pittorica, &c.)

ROMANIA ANDREAS and BERNHARD, eminent German composers, were the eldest sons of brothers who enjoyed a considerable share of reputation as instrumental performers during the middle and latter part of the last century. Andreas was born at Osnabruck in 1677; Bernhard in 1770. Both held appointments in the royal chapel of the Elector of Cologne, at Bonn, about the year 1708. The former began a great reputation on the violin; the latter as an almost unrivalled player on the violoncello; and both by their compositions, even at that early period of their career. The progress of the French armies at the commencement of the revolutionary war drove the two cousins to Hamburg, where their talents immediately procured them engagements. In 1795 they settled in Paris, and visited many parts of Germany and Italy, establishing their reputation, wherever they presented themselves, as professors of the first class. They returned to Hamburg in 1797, where the elder remained; but the younger left that city two years after, and proceeded alone through England and Spain to Lisbon, where he obtained a good situation in the royal chapel at Berlin. Andreas in the meantime turned his attention more exclusively to composition, and produced four operas; he also set Schiller's Ode to Music. For the church of St. Dominick in Paris; Roumth with another friend for four voices, and a pater Noster for three, besides many psalms. For the chamber or concert-room he composed much music, Schiller's Song of the Bell (Das Lied von der Glocke) and other things, which the Parisian noisemakers in every part of Europe. He also produced two full operas, Die Grossmuth des Scipio (The Magnanimity of Scipio), and Die Räumten von Palermo (The Ruins of Palermo), the drama of the latter from Mrs. Radcliffe's Italian; and, if an opinion of the work may be formed from a pianoforte arrangement, it seems to be an opera that might succeed in the fashionable theatrical theatres.

Bernhard, while in Berlin, wrote two magnificent and much instrumental music, particularly for the violoncello. Both cousins indeed were for a time chiefly known as authors by their compositions for their respective instruments. Their posthumous fame is mainly attributable to their symphonies and overtures, the best of which have become familiar to the amateurs of this country by the admirable performance of them at the concerts of the Philharmonic Society.

Andreas Romberg died in 1821, and leaving a family in embarras circumstances, a concert for their benefit was generously got up in London by the Philharmonic Society, which was conducted by Mr. Davis and Mr. D'Albert, and in whichpointed one of the professors at the Conservatoire de Musique at Paris, in 1801, and created Chevalier of the Legion of Honour, but retired from the office two years after. He came to London in 1803, and, after various visits of this country, gave a concert, by which he was not a greater, either in purse or reputation; for impropriety, not to say presumptuously, fixing his tickets of admission at a guinea, his auditors were few, and his own performance too wild, he announced either the decay of his powers, or that he had not kept pace with others in the improvements of his art. He died in 1841.

(Romantisches Lexicon; Harmonicum, vol. i.)

ROMISH CHURCH. An account has been elsewhere given [Patriarch, P. C., vol. xii. p. 317] of the rise and nature of the patriarchal dignity. It may be added to what has already been said, that the patriarchal dignity in the fifth century was occasioned by the erection of the bishopric of Jerusalem (which had previously been subordinate to the archbishopric of Caesarea) into a patriarchate. It is a curious indication of the little difference that actually supplied to superior antiquity and apostolic origin, that the Christian Church first established, and which enjoyed, at its origin, a supreme position, not of one only of the apostles, but of all, was the last that received ecclesiastical rank; and hardly ever were its patriarchs enabled to compete in power and influence with their fellows of Rome or Constantinople. We here give a table of the patriarchs down to the capture of Constantinople and the overthrow of the Eastern Empire, A.D. 1453. We give the occupants of the patriarchate seen from the time of their asserted foundation, with the date of the
accession of the respective bishops or patriarchs, according to the generally received computation; but we may observe that the succession of the earlier bishops is very obscure, and that the asserted apostolic foundation of the several churches (with the exception of Jerusalem) is quite destitute of Scriptural support, and has been vehemently disputed: not to speak of the question as to whether the government of the primitive Church was, in the modern sense of the word, episcopal or not. The bishops of Constantinople, who was bishop in the early part of the fourth century, are especially doubtful.

In the fourth century the succession is perplexed by the schism occasioned by the Arian controversy; and from the sixth century, owing to the Jacobite schism, there has been a double succession in the patriarchates of Alexandria (the Jacobite patriarchs of which are sometimes, from their nation, called the Coptic patriarchs) and Antioch: and the perplexity in the patriarchate of Antioch has been occasionally increased by the rivalry of contending Jacobites, as in the schisms of the thirteenth, fourteenth, and fifteenth centuries. After the conquest of Palestine and the greater part of Syria, by the first crusaders, and the capture of Constantinople in the fourth crusade, the confusion was made still greater by the appointment of Latin patriarchs at Antioch, Jerusalem, and Constantinople. In order to prevent mistake, we give in Roman letter the prelates who were regarded by the Greek government and church as the legitimate holders of the see, without regard to the orthodox or heterodox of their opinions individually: the Jacobite prelates are given in italics, and the Latin patriarchs of the East in small capitals. We give the names in the usual Latin form, which has, in most cases, continued in use in English books; the few cases in which the names have been Anglicized are not, as the reader will easily recognize John in Joannes, Peter in Petrus, Mark in Marcus, Theodore in Theodorus, &c.

The list of the popes given elsewhere [For*, P. C., vol. v. p. 405] is restricted here for the sake of comparing dates, &c. The chief authorities employed by us are Le Quien, Oriens Christianus; Fabricius, Bibliotheca Graeca, vol. vi, vili, xii, xiv, ed rec, viii, xi, xii, ed Harold; the Practica Præcipuorum, given in the Acta Sanctorum of the Bollandists; Maii, vol. iii, July, vol. iv, Augusti, vol. i; Bandurius, Imperium Orientalis, vol. i, p. 167, &c.; and L'Art de Vérifier les Dates, the dates of the popes in Fabricius are generally taken from the Acta Sanctorum, so that these two authorities are, in most cases, identical.

When two years not consecutive are assigned as the date of accession, it must be understood that the year of accession is not agreed upon, but that it occurred either in the earlier years, or in the interval between them. Dates at the end of a name show that the person named was patriarch in that year or in those years, but that the year of accession is unknown. A, subjoined to a name, denotes Arian; M, Monothelite; Ic, Iconoclast; J, Jacobite, or Monophysite; H, Heretic (reputed), without reference to the nature of his heresy.

* It is very doubtful if there were more Popes than one of the name of Clitus or Anacletus at this early period; and whether, if there was only one, he is to be placed before or after Clemens I.

† This See was deposed by the Arcans, to whose doctrine he was extremely opposed, and died in exile. A party of his adherents broke off from the church and formed a sect which existed for some time under the name of Rustikhana.

‡ Most of the authorities give the bishops between Onesimus and Olympius in the following order; and omit the length of each episcopate, which, as given above, is evidently too great, as may be seen by adding them together.

§ In L'Art de Vérifier les Dates, the three prelates next preceding Metropolitans are thus given:
A.D. 329, Libanus. During his exile Pelagius was set as papal vicar, and is on
that account sometimes enumerated among the Popes as Pelagius II., which
causes a difference in the numbering of later Popes of that name.

ROPES, RIGIDITY OF. [RIGIDITY OF ROPE, P.C.S.] ROSAL/LINA. [FORAMINIFERA, P. C. S.]

ROSELLI, COSIMO, a celebrated old Florentine painter, was born at Florence, according to Gaye, in 1498. There are few of his works remaining; the principal is the fresco in the convent of Sant' Ambrogio, at Florence, painted in 1465, according to an inscription seen upon it by Rumohr, when Cosimo cannot have been more than eighteen years of age according to the above date: Vasari however says it was painted in his youth. And Rumohr observes that Cosimo, in the commencement of his career, followed the path which was marked by Angelo da Firenze and Masaccio; but that after a few brilliant examples of his ability, he left the approximation of the representation of things as they really appear, to follow an uninteresting, inane, and ugly manner. The fresco represents the transportation of a miraculous-working chaflie from the church of Sant' Ambrogio to the episcopal palace; the abbess and monks follow in the procession, and at the palace-gate is a group of priests and choristers ready to receive it: around is a crowd of curious spectators. The story is told, and the picture described, in Richa's 'Chiese di Firenze.' The picture has been engraved by Lainino for his series of old Florentine paintings, and there is a group from it in Lusi's 'Ettria Pittrici.'

Cosimo was one of the painters invited by Pope Sixtus IV. to Rome to paint the Cappella Sistina, built in 1475, by Baccio Battisti [Piantelli, P. C. S.], for that pope. Cosimo's paintings in this chapel are still in good preservation; there are—the Destruction of Pharaoh's Host in the Red Sea, in which the Israelites are also represented returning thanks for their deliverance; Moses receiving the Tables of the Law while the Israelites are without possessing the golden calf; the Sermon on the Mount, and the healing of the Leper; and the Last Supper. The landscape of the third picture was painted by Cosimo's pupil, the eccentric Fierio Cosimo, afterwards the master of Andrea del Sarto. These works were painted for a prize in competition with others in the same chapel by Sandro Botticelli, Domenico Ghirlandajo, Don Bartolomeo, Luca da Cortona, and Pietro Perugino. Cosimo was very anxious to get the prize, but he doubted his ability; at the same time that he had little faith in the pope's judgment; he therefore, knowing his weakness in composition and design, painted his picture very high in colour, and used plenty of ultramarine and gold, aiming to attract upon the pope's fancy by his gay display. When the pictures were all uncovered, his fellow painters laughed at Cosimo for his pomposity. Cosimo however proved himself a good man of the world, if not a good painter; his gay works fixed the pope's attention and he obtained the prize; the other painters were censured by his holiness for not using finer colours, and they were obliged to retouch them and heighten their effect in the same manner, to the great triumph of Cosimo, whose works however were in reality inferior to all the others.

Cosimo Roselli was still living in 1506: Vasari says he was sixty-eight years old when he died; if therefore we were born in 1459, 1507 may have been the year of his death. He was the master of Frabartolomeo. (Vasari, Vita de' Pittori, etc., ed. Schorn; Rumohr, Italiensche Forschungen; Flatter and Bunsen, Beschreibung der Stadt Rom, vol. ii., Pt. 1; Gaye, Carteggio intorno d'Artdt, vol. ii., ap. 1.)

ROSELLINI, IPPOLOTO, Cavaliere, was born August 13, 1800, at Fies. His father was a merchant, and Rosellini himself was designed for his father's business; but he acquired such a love of the study of antiquities from his first tutor, Padre Battini, a Servitiant monk of St. Antonio, who was a tolerable numismatist, that he commenced at an early age to give himself up to those studies for which he afterwards distinguished himself, and the mercantile career was wholly abandoned. In 1821 he finished his university studies in Fies, and took the degree of Doctor of Theology. He afterwards studied the Oriental languages for three years with the celebrated (now Cardinal) Mezzofanti at Bologna; and
in 1824 he was appointed professor of Oriental languages in the university of Pisa. In 1825 he appears to have devoted himself to the study of Egyptian hieroglyphics, following the steps of Champollion, of whose discoveries he was an ardent advocate. When Champollion, in 1826, for the further development of his system, examined the Egyptian monuments in Rome, Rosellini, by the permission of the Tuscan government, attended him in his researches; and he accompanied him to Paris, and there spent the autumn of that year in similar researches: he published in the same year "Epigrafi Egiziane" in the gallery degl' Uffizi at Florence.

In the autumn of 1827 the Grand Duke Leopold II. granted Rosellini a year and a half leave of absence, and he founded five companions upon a similar expedition at the same time, and they all embarked together at Toulon, July 31, 1828, and landed on the 18th of August following in Egypt, where they remained fifteen months, exploring all the principal monuments of Egypt and Nubia.

Rosellini arrived at Pisa January 6, 1830, and commenced immediately a course of lectures on the Egyptian hieroglyphics, the subject of which is in "Le Elements Linguistici Epygrafsici" of Padre Ungarelli, published at Rome, in 1837. Rosellini had himself made his principles known in a letter to M. Peyron, in 1831. The great results of the expedition however were not to be derived by Chauchand and Rosellini; the former undertaking to explain all the historical monuments, and Rosellini the civil and religious. This design was however rendered impossible by the death of Champollion, which took place March 6, 1832, and Rosellini expressed his sincere regret and disappointment in a epistle on his death, which he published under the following title—"Tratto di ricorrenza ed amore alla memoria di Champollion." Rosellini was thus compelled to undertake the whole work himself, which was his original design, and the prospectus explaining the plan of the work had already appeared in January, 1831. Accordingly in November, 1832, appeared the first volume of "I Monumenti dell' Egitto e della Nubia," by Rosellini alone, explaining the historical monuments; the second appeared in 1833; and by 1836 three more, explaining civil monuments, were published; but between the publication of the fifth and sixth volumes a long interval occurred, partly through Rosellini's appointment as librarian of the university of Pisa, but chiefly through a serious illness which he was afflicted in the chest, and which incapacitated him for nearly two years. At the same time, with the above volumes of letter-press, appeared two large folios of illustrations, the historical monuments in 1832, and the civil monuments in 1834. The historical monuments was completed in 1838-41, in two volumes, the third being divided into two parts, making in all four volumes in five on the historical, and three on the civil monuments, and these were published during Rosellini's lifetime.

The remaining part were the religious monuments of the Egyptians, which he was occupied upon until the period of his death, and though he did not live to see the publication, he completed a MS of this part.

In 1830 he gave up the professorship of Oriental languages and commenced a series of archaeological lectures; but in 1841 these labours were remitted him on account of his extremely bad health, and in 1843, he might be supposed a time that he might descend to study to the completion of his great work on Egypt. On the 16th of May, 1843, however, his case was serious, and he died on the 18th of May following, in his forty-third year. The third part of the work was published in 1844, under the direction of the professors Bonani and Severi, in one volume of illustrations and one volume of text.

This great work on Egypt, yet unrivalled as a review of Egyptian art and customs, though in a scientific-literary view it treats only upon the threshold of Egyptian history and antiquities, is briefly described in "I Monumenti dell' Egitto e della Nubia" di Scipione Sciapola, published at Rome, in 1844, one volume, with four volumes of text, 1832-41; the second, Rosellini, contains the civil monuments, "I Monumenti Civili," in 156 plates, with three volumes of text, 1834-46; the third, containing the religious monuments, "I Monumenti Religiosi," in 175 plates, with four volumes of text, 1832-46; the second, Rosellini, contains the civil monuments, "I Monumenti Civili," in 156 plates, with three volumes of text, 1834-46; the third, containing the religious monuments, "I Monumenti Religiosi," in 175 plates, with four volumes of text, 1832-46. An index of the whole work is said to be in preparation by Rosellini's pupil Giuseppe Bernardi, who published a short Life of Rosellini at Florence in 1845—'Biografia del Professore Ippolito Rosellini,' of which an abstract appeared in the "Allgemeine Zeitung" and in the "Kunstzeitung," and is still in print; and which has been used in the biographical portion of this article. Rosellini bequeathed his Egyptian MSS. to the university of Pisa; the drawings and plates are all the property of the Grand Duke. Among the MSS. is a voluminous but unfinished "Dizionario Geroglifico," Hieroglyphic Dictionary, with several thousand names.

ROSHAN is a small tract, and a part of that immense region of Central Asia which is called Turan or Independent Turkestan. It lies between 37° and 38° N. lat., and between 70° and 72° E. long., but its extent is not well known, as the country has never been visited by Europeans. It is a very mountainous country, with valleys and ravines of all kinds of which constitute the western declivity of the Bolor Tagh, and surround the elevated table-land of Pamir. Along its southern boundary runs the river Oxus, which in these regions is called the Media, and it cannot be crossed for the greater part of the year. This circumstance, and the great quantity of snow which covers the higher portions of the mountains for nine or ten months, render the country almost inaccessible except after several months of summer, and in the month of January, when the river, notwithstanding its rapidity, is frozen over in many places. The cultivation of grain is limited to wheat and barley; several kinds of fruits are much cultivated, such as melons and mulberry-tree is much cultivated, and the fruit is used for making flour. Horses are numerous: the camel with two hunches is the principal beast of burden. Caravans travel both through the desert and the mountains. The inhabitants, whose number is not stated to exceed a thousand families, speak a peculiar language. The sovereign of this country is dependent on the khan of Kunduz, but this dependence is only nominal.

(Wood, Journey to the Source of the River Oxus.)

Rosienni, Carlo De', born in 1787 at Rovereto, in the Italian Tyrol, studied at Innsbruck, and then in his native town, where he began early to show his aptitude for literary composition by writing several dissertations on poetry. He afterwards removed to Ferrara, where he published in 1803 a collection of 789 auctoribus. In his "Istituzioni" were added a letter by Vannetti on the style and the language of Ovid, and a parallel between the Orpheus of Ovid and the same character in Virgil. This work obtained for Rosmini the patronage of the most honorable citizens of the Florentine academy. He next wrote: 'Della Vita di L. Annone Seneca libri quattro,' Rovereto, 1793. In 1801 he wrote an account of Vittorio da Feltre, a celebrated preceptor of the fifteenth century, and of his system of education: 'Idea dell' ottimo F cicredore nella Vita e Disciplina di Vittorio da Feltre e de suoi Discopoli.' This book may be called a treatise on pedagogy, as well as the next work published by Rosmini on Guarino Veronese, a contemporary of Vittorio da Feltre, and upon his school: 'Vita e Disciplina di Guarino Veronese e de' suoi Discopoli,' 3 vols. 8vo, Brescia, 1805-6. In 1808 Rosmini published an carries on the learned Filosofo: 'Vita di Francesco Filippo da Tolentino,' 3 vols. 8vo. His next work was a Life of Trivulzio, a great captain of the sixteenth century: 'Dell' Istorior intorne alle Milizie Imprese di Francesco Trivulzio detto il Magno Libri XV.,' 2 vols. 4to., 1816, a biography enriched with handsome engravings and valuable documents. The last work of Rosmini was his history of Milan: 'Dell' Istorior intorne alle Milizie Imprese di Milano,' 3 vols. 8vo., 1816. This history is very valuable, as it gives an account of the reign of Frederic Barbareossa down to 1555, when Milan was annexed to the dominions of Charles V. The author wrote a continuation of it down to the beginning of the reign of Charles Emmanuel III., but was prevented from finishing it. Rosmini ranks among the principal Italian biographers of their time. He died at Milan in 1827.
Rossi, Rosso De', or Il Rosso, called in France, Maître Roos, a celebrated Florentine painter, was born in Florence in 1496. He studied the works of Michael Angelo, and his style is the figure of a dying sultan; Victory is abroad with him with a laurel. Lord Rodney's monument is a pyramidal group, the statue of the admiral forming the apex; below is Fame communicating with History.

Art-Union Fund; Companion to St. Paul's Cathedral.

Rota/Lia. [Fontainel, P. C. S.] The most abundant genus of the Foraminiferal order, in the Cretaceous system of strata. Many of his works have been engraved. (Vasari, Vita de' Pittori, etc.; Lettere Pittoriche; D'Argenville, Vies des Peintres.)

CLEMENS FELIX, B.A., was born at Nottingham in 1762; his father, a native of Siena, though not a licensed practitioner, practised as a medical man at Nottingham. Young Rosso was apprenticed very early to a sculptor, and his extraordinary precocity was so marked that after he had served his time, a journeyman, at eighteen shillings per week, but being employed by his master to correct some work on which Lucchetta's principal assistants had been engaged, he suspected that his own abilities were of a superior class, and he demanded and obtained higher wages. It was now, however, having once felt the longings for praise, impossible for him to remain in his then subordinate situation, and he determined to seek his fortune elsewhere. He arrived in London. There, still a boy, he entered himself as a student of the Royal Academy; and in 1781 he obtained the silver medal, and in 1784 the gold one, which entitled him to three years' maintenance at Rome. He went to Rome in 1785; in 1788 he returned to London; in 1800 he was elected an associate of the academy; and only two years afterwards, a very short interval, he was elected an academician. He was subsequently appointed sculptor to the Prince Regent, and he was employed in decorating Buckingham Palace. He was afterwards sculptor to William IV. But he had little to do after the completion of his great public monuments in St. Paul's Cathedral, and he determined to quit his situation, and retire to Florence upon a pension from the Royal Academy. He died February 21, 1839. He was twice married, and had eight children by each wife.

Rossi was both a classical and a monumental sculptor, and his style was manly and vigorous, especially in his monumental works, but they are not remarkable for any refinement either of sentiment or of sentiment. Of the first class the following may be mentioned:—A Mercury in marble, executed in Rome; a recumbent figure of Eve, in marble; Edwin and Eleanor; Celadon and Amelia; Messidor; Zephyrus and Aurora; and Venus and Cupid. A statue of Thomson the poet by him is in the possession of Sir Robert Peel; and there is a large colossal statue of Britannia on the Exchange at Liverpool. His best works, however, and those by which he is and will be known, are the following monuments in St. Paul's Cathedral:—The Marquis Cornwallis, the navel; Captain Faulkner and Lord Heathfield, in the south transept; and Captains Mose and Roux, and Lord Rodney, in the north transept. The subjects of these are all officers of Lord Cornwallis, Heathfield, and Rodney, and Captain Faulkner: all of which, except the second, are groups of three of more figures of the heroic size. That to Lord Cornwallis is placed opposite that of the Duke of Wellington, and is in a similar style of composition and on a similar scale, it is a pyramidal group, the Marquis, as a Knight of the Garter, on a pedestal forming the apex; below are three allegorical figures—Britain, Victory, and Fame—standing before a castellated rock to crown a warrior on the sea-shore with laurels.
In 1840 the Baden government re-admitted him as a lay benedictine. He retired to Freiburg in 1843; after a serious illness, rendered worse through the moral sufferings he had been exposed to, Rotteck died on the 20th of November, 1840. His death was mourned as a public calamity in all Germany.

The principal work of Rotteck is his 'Allgemeine Weltgeschichte' mentioned above, which extends from the commencement of authentic history to 1815. It went through fifteen editions, the last with a continuation down to the years from 1815 to 1840, by K. H. Horns, Brunswick, 1841-45, 11 vols. 8vo., of which nine are the work of Rotteck, and the two last the continuation of Hermann. No general history is capable of such splendour and of such production of Rotteck; in Germany it is in the hands of almost every educated family; its fame soon spread over Europe and America; and it was consequently translated into most of the European languages. The English translation by T. Jones, Philadelphia, 1840-42, four vols. 8vo., 2nd edition, London, 1842, is however only a translation of an extract of the 'General History,' which Rotteck published under the title 'Aszam der Weltgeschichte,' Freiburg, 1831, &c. four vols. 8vo. Contrary to the practice of most German historians, Rotteck simply relates history, indulging neither in critical investigation of trifles, nor in metaphysical contemplation of the broad facts of history. But the whole is represented from a liberal point of view, and enlivened by sound reflections on the origin of freedom and slavery, and the causes of the rise and fall of nations. The style of Rotteck is clear and attractive, but sometimes a little too much interrupted; and every page shows that the author possessed that rare taste and that discretion which enable a man to distinguish between trifles that are important facts, and to give neither too much nor too little. The reader wishes to obtain a strong impression of the peculiar merits of this work, as the production of a German historian, need only compare it with Ham- mene's far-famed History of the Turkish Empire. Among the other works of Rotteck we mention 'Kleine Schriften' (Minor Works), five vols. 8vo., 1829-1835, which contain a great number of valuable memoirs, essays, letters, &c., on various historical and metaphysical subjects, 'Lehren der Vaterlandesrechte und der Staatswissenschaften' (Doctrine of Law as a Metaphysical Science, and of Public and Constitutional Law), four vols. 8vo., 1820, &c.; 'Staatsrecht der Constitutio-

ROVERE, DELLA, the name of a noble family originally from Savona, in the territory of Genoa, which gave to the church two celebrated Popes [Sixtus IV. and Julius II., P. C.] besides many cardinals and other distinguished persons. Pope Julius II. caused his nephew Francesco Maria Della Rovere to be adopted by Guidobaldo of Montefeltro, Duke of Urbino, who was childless, as his successor in the duchy. Accordingly, after the death of Guidobaldo in 1507, Fras-

Guidobaldo died in 1574, and was succeeded by his son Guidobaldo, who, as described above, had been from the times of the Montefeltro family, a favourite resort of men of science and of literature. Francesco Maria I. had been a patron to the celebrated naturalist Aldo-

RUBRUQUIS, WILLIAM DE. This distinguished traveller of the middle ages, was a friar of the Minorite Franciscan order. Pits, or Pitacus, an English Catholic of the sixteenth century, in his curious biographical work—

'Vives de los Reyes, Bisbes, Apóstolico Men, and Writers of England,' claims him as a Christian, and as one that did honour to his country. It appears, however, pretty plainly that he was a native of Brabant. His real name was Royalbrock, or Hybruck, which, according to the fashion of the time, in Low German, means a river. It is possible that his birth is not preserved, but he was probably born about the year 1288. He entered the cloisters early in life, and soon after completing his noviciate and taking the major vows, he went to the Holy Land, with other orders of the cloister. The recent successes of the fourth grand crusade under Louis IX. of France, afterwards crowned as Saint Louis, had revived the hopes of the Christian states, which streams of pilgrims were flowing thither; and some of these couples upon setting up their tabernacle of rest in Jerusalem, and upon finding provision and settlement for life in the Holy Land.

But before Rubruquis could reach the Syrian shore these hopes were overtaken; the devout French king had been defeated near Tunis, rather by endemic diseases than by the.
sward of the Saracen, and had been made prisoner, with the
remnant of his host, by the Mohammedans. Louis, however,
was soon released upon paying a ransom, and entering into
a treaty with the Selden; and he was in Palestine in 1253.
Although some monkish reports had been sent in quest of that great, undiscoverable, Christian potentate of
the East, Prester, or Priest John, had returned disappoint-
ment, and with very discouraging accounts of the difficul-
ties and perils of their journey, King Louis could not dis-
charge his imagination of that visionary personage; and being
more anxious than ever to contract an alliance with that fan-
catic chief, he determined to make his own search of him.
A report had reached Louis that the great Tartar, Sartach, son of Bautu-Khan, who commanded in the
western parts of Tartary, was a good Christian. If this
Sartach were converted, Prester John said, the Christian
world, if truly reported, must make him a valuable ally to the
Christians who were warring in the Holy Land against the
Peyrims. The mission of Louis was, therefore, to find that
Tartar prince, wherever he might be, and at whatsoever
toll and danger. It was composed of Rubruquis, friar Bartholom-
ew of Cremona, and a certain friar Andrew, whose country
or birthplace is not named. Rubruquis, though the youngest
of the three, appears to have been considered as the head of
the mission. His, no doubt, owed this pre-eminence to his
superior scholarship, wit, and courage. Before his departure
King Louis strictly enjoined him to write down everything he
heard or saw that was of importance, but at the same time
obeying the royal order, and by making a good use of his
eyes (his ignorance of the Tartar languages made his ears of
less account), he brought back a great deal of curious informa-
tion, which has given much light to our knowledge of the
quaint journey. After spending a short time at Constantinople among
the Greek Christians, whose schism gave them great offence,
Rubruquis and his companions took ship, and entered the
Euphrates or Black Sea. But in the month of April 1254, they
were safely landed at Solida, now Soudack or Soujak, in the Crimene,
not far from Cherson, where Howard the philanthropist died
in 1796. But here their troubles began. They had brought
not even a tunic to entertain themselves with, or to carry
ports all through the East. They were told that they
would never get at Sartach unless they had rich gifts to lay at
his feet. They, however, pleaded their vow of poverty, as
Franciscans, and boldly went on, travelling sometimes in
carts, and sometimes on rough horses. They crossed the
Steppes which separate the Dnieper or Boryzhenes, from
the river Don, or Tanais, and then directed their course due
east, over immense desert plains where nothing was to be
seen but earth and sky, and here and there the barrows or
tumuli of the Comans. On the 22nd of July, being in a
fruitless condition, they reached the banks of the Don, where
they found some fish, but not enough to eat them. On the
12th August, the river they plunged again into the hungry desert. On
the 2nd of August they reached the temporary residence or en-
closure of the Khans. As they had nothing to give,
beyond a little sweet wine, a few preserved meats, and
big full of sweet biscuits, their reception was of the sorriest.
They soon discovered that Sartach's Christianity was all a
dream. That Prester chief, however, determined to send
them on to his father Bautu. From his encampment they
did not continue their journey until they came to Mashch-Khan, the father of the Khan, who had previously been
found somewhere in the direction of China. Of this long
journey of hunger and thirst, cold and fatigue, there was no
end. At last, on the 27th of December, the poor monks arrived
at the encampment of the Khan, who was living in a
bark crossed a lofty range of mountains, and had travelled
due north. The emperor was attended by many Chinese manda-
rians, and by ambassadors from India, from Persia, and from
Traveller, by the court of a state, if he had not drunk on cosmic, or the fermented
milk of mares. On the 5th of January (1254) the friars were presented at
court, where they had to perform several humiliating ceremonies.

P. C. S., No. 149.

Vol. II.—3 T
which province the family of Rufio had large estates, and excercised considerable local influence. The queen approved of the plan, however hazardous it might appear, and made the king an offer of 200,000 ducats on the first day of his rank of his salute. Rufio, glad to escape from the intrigues and vexations of the court of Palermo, accepted the offer. In February, 1799, he crossed over in a boat with only five men and three passengers. He landed at Baghara, a seat of his family. He collected a number of adherents, and unfurling the royal flag with a white cross, proclaimed a crusade against the French and their partisans. The inhabitants of Naples had committed many acts of oppression in the provinces, and had exasperated the rustic population, which were not ripe for the change from old absolutism to a republican form of government. The Calabrians, emboldened by thousands to Rufio's standard, marched against the town of Monteolone, which surrendered by capitulation, as well as Catanzaro; it afterwards stormed Cetrone, which was given up to plunder; took Cosenza though the treaty of its commander; and thus in less than a month Rufio was master of all Calabria, where he re-established the king's government. He was joined by many regular officers and soldiers, and was supplied with artillery. He then took the road to Apulia, and laid siege to Altamura, which opposed his passage. The inhabitants defended themselves despairingly, but the town was taken and plundered for three days, and the inhabitants were massacred. The Aragonese, in other parts of Apulia hoisted the royal flag; the Abruzzi was already in open revolt against the republicans of Naples, who were soon after abandoned by the French troops, which were in the middle of May, led by General Bertinetti, receiving the order to oppose the Austrians and Russians, who were predominant in that quarter. Naples was left to its fate with only a small French parron in one of the castles. On the other side Rufio was joined by some regular Russian and Albanian forces from Corfu. He then advanced towards Naples by Avellino, and surrounded the capital at the head of from fifty to sixty thousand men, mostly irregulars. After some fighting outside of the town, an insurrection of the lower orders from within facilitated the entrance of Rufio's bands, and the town became a scene of carnage; but the republicans still defended themselves in the castles and the adjacent districts, where they had fortified the massive palaces and houses. Rufio, willing to spare further destruction, entered into a convention with the republicans, who were to be spared off for France. The convention was signed by him, and a part of the republicans were actually sent off to France, when King Ferdinand arrived from Sicily the bay, at the end of June, on board the English admiral Nelson's ship, and refused to sanction the capitulation. Rufio had exceed all powers in treachery of rebels, and he appointed a special court to try the republicans, many of whom, chiefly of the higher orders of society, were put to death. The minister Acton charged Rufio with the executions, and the court on his request for the Jacobin and the cardinal, disappointed and humiliated, seized the opportunity of leaving Naples for the concile, which had been summoned to assemble at Venice for the election of a pope. Rufio was made Prefect of the Annona, a post he held for the next four years, until his departure from Naples in 1783. He then returned to Rome, where he remained till 1809, when he went to France and made his peace with Napoleon, and he was one of the Cardinals who sanctioned by his presence his second marriage. In 1814 he rejoined Pope Pius VII. at Rome. After a time he returned to Naples, and took again his seat in the council, where he displayed a marked moderation of sentiments. He went to Rome in 1823 to the conclave in which Leo XII. was elected, and died at Naples in 1837 at an advanced age.

Rufio was a man of ability and accomplishments. He was worldly and lax in principles, by no means fanatical or even pious, in which regard his other romantic expedition of 1790 cannot be justly attributed to him, although he may be blamed for not reckoning on them before he put himself at the head of the insurrectionary movement. The republicans of Naples had assumed a task beyond their strength; they mistook their own coterie for the nation, and they suffered cruelly for it, for the people were not on their side. The same error has been repeated again and again in other countries. There is a group of books, published by Knight & Co. in 1837.

Contemporary with this Rufio, there was another Cardinal Rufio, who was a nephew of the first, and the head of the branch of the same family, who was archbishop of Naples.

(Petroni, Storia della Spedizione del Cardinale Rufio; Colletta, Storia del Regime di Napoli; Coppi, Annali d'Italia.)

RUFIO, a celebrated German battle painter, was born at Augsburg in 1666. He was the pupil of Caspar Fischbach, an eminent historical painter in his time; but Rufio devoted himself at an early age almost exclusively to battle painting, in which he was partly confirmed by the admirable battle-pieces of Bourgignon, Lebbeke, and Tempesta, which he studied on his journey to Vienna and Frankfort. He was invited by the Fleming Schilder-Bent, or Society of Painters, in which he was received, from his predilection for battle painting, under the nickname of Schild: all the members of this society were known by surnames.

In 1795, after an absence of five years, he returned to Augsburg, and had the opportunity of witnessing its siege in 1708, and of thus studying from nature what he had hitherto only acquired from his imagination and from the pictures of others. He lost a great portion of his property through this siege, but what he lost in substance he gained by excellent opportunities he found of perfecting himself in the line of art which he had adopted, and he acquired extraordinary excellence as a battle painter; and became distinguished also for his etchings of battles and skirmishes: he excelled in the manner in which he represented smoke, and made use of it in separating and arranging his groups. There is or was a large picture of the siege of Augsburg in the Stetten collection at Augsburg. Rufengas was made director of the Academy of Augsburg in 1710; he died at Augsburg in 1742. His pictures are very numerous, and there are not many collections without one or more examples of his style. He painted besides battles and skirmishes, horse-markets, and horse-trade, and his being a haberdasher enabled him to put his pictures on a larger scale. His design is vigorous and bold, but his colouring is unequal, sometimes being high and warm, and at others heavy and monotonous: and though his light and shade is often well disposed, yet the expressions which they are intended to give are often too black and obscure. Owing to an illness he painted many years with his left hand. There is a picture of the battle of Blenheim by Rufengas. He was the ancestor of a numerous family of battle painters, of whom the most famous was son of him by J. C. Füssli was published, together with a Life of Kupetzky, by the same writer: Leben Georg Philipp Rusch und G. Johann Kupetzky; Zürich, 1746.

Christian Rufengas, his second son, engraved about sixty of his father's designs in a very spirited manner, chiefly in mezzotinto. His original etchings, of which there are about thirty, are much prized.

RUISCH, RACHEL, a distinguished Dutch flower-painter, was born at Amsterdam in 1664: she was the daughter of Professor Ruisch, who had taught flower-painting by himself. He was the painter of his two sons, and the father of the Elector of the Palatinate, and of the present Elector of Hesse, who was one of the chief members of his family. In 1695 she married to the portrait-painter Juriaen Pool, who was two years her junior, to whom she bore ten children and with whom she lived fifty years. In 1701 she and her husband were elected members of the Society of Painters of Amsterdam, and in 1792 she was elected the elector of the Palatinate, appointed her his court painter. She died at Amsterdam in 1760, aged eighty-six, and she continued to paint till she was upwards of eighty years old. Her works include a portrait of The Elector of Hesse, the Elector of De Heem, and have sometimes been sold for very high prices, even 8,500 francs for a single picture.

(Van Gool, Nijmegeen Schouburg der Nederlandsche Kunst-schilders; Waddington, Dictionary of Painters, in those times still called Lijnen, Geschichte der Vaterländische Schilderschun, etc.)
RULER, PARALLEL. A good form of this instrument is explained in Marquoz's Rulers, P. C. S., which is particularly applicable to the case in which numerous and related parallel lines are wanted in the same space. The ordinary parallel instruments are of two kinds, which might well be called parallel rulers and parallel rollers.

The principle of the common parallel ruler is a parallogram of equal sides, with its sides and angles altered, the other side changes position, it and its parallel always remaining parallel to the first side and its parallels. Two rectangular rulers are connected by two crossbars of equal length, and are connected in such a manner that the four pivots, two in each ruler, shall be the four points of a parallogram. The line joining two pivots on either side is always parallel to the length of the ruler. One ruler being held fixed, and a line drawn with the edge of the other ruler in any position, then any motion given to the other ruler by the rotation of the crossbars gives, on the edge of the moving ruler, a line parallel to the first line. The defects of this construction are, that the four pivots may not make an accurate parallogram, in which case the instrument is worthless: and the sides of the two rulers, when the instrument is closed, may not be parallel to one another, in which case all the lines must always be taken off the same ruler. Moreover, one ruler remaining fixed, there is but a small command of distance from it; so that, to get at much space, the process of first moving the line which has to be advanced, the second brought up to it, the first ruler advanced again, and so on. Now, owing to the rotation of the pivots, this gives an oblique motion to the instrument; so that it is not certain that what is required is gained, the point through which it is to be drawn is off the ruler. To meet this disadvantage, and to give the instrument a more extent, three rulers are sometimes put together, each connected with the next by cross-bars in such manner that the cross-bars connecting the first and second have an opposite revolution to those connecting the second and third. At its best however this instrument is rather clumsy; but, such as it is, it is safe and easy to learn, and will make good work when well learned.

The simplest kind of roller is the common round roller, which, with a little practice, will draw parallels for ordinary use very well. It is good practice in the use of instruments to draw parallels in this way; the ruler being held in the middle and gently allowed to take its own rolling motion. If a ring be well drawn round the ruler, it is good practice in drawing perpendiculars to adjust the ruler so that the ring may roll over the line to which perpendiculars are to be drawn. But a roller which is more easily used is sold in all the shops. It consists of an ordinary roller of rectangular form, either of which are bored and divided into equal parts, and the side of the roller being in inches and twelfths; the inch divisions being made to come exactly opposite each other. A roller is set into room cut out of the line of the ruler in such manner as to project a very little way from the roller, the line of the roller being of inches. When the instrument is put down on the paper, either of the bored edges may be brought down on the paper, or both may be carried down. The metal body, which is also called a roller (to which are fixed cylinders, the middle part being in a frame) rolls easily, and additional stability is given if, while it rolls, one of the bored edges be kept slightly upon the paper. The ends of the rollers are graduated and a fixed index is in the frame, so that by allowing equal numbers of divisions to pass the index at each roll, a good approximation (though not quite with a draughtsman's accuracy) may be made to equidistant parallels. Perpendiculars to a given line are drawn by adjusting the ruler so that opposite divisions of the bored edges may travel on the given line. With a very little practice this is an instrument of great power and accuracy. Before using it, draw a line with it, roll it away, and then roll it again to that line, and see if the coincidence is as perfect as before. Various other modes of trial will suggest themselves: indeed no one should use a parallel ruler at all until he has done this a sufficient number of times, and satisfied himself that he can get the opposite sides quite equal.

A rough construction of this kind is now (very recently, September, 1840) sold under the title of 'Schleicheng's Parallel-Roller.' It is a metal box, bored in a flat bored roller, so as to carry it when it rolls. This is meant to rule lines for writing, but it may be made to do good service as a parallel ruler for other work.

ROUMOH, CARL FRIEDRICH LUDWIG FELIX, VON a distinguished writer on art, was born of an old family...
"... were followed, in 1637, by a treatise, 'Zur Geschichte und Theorie der Formschneidekunst.'"

"In 1837 he made a fourth journey into Italy, but he did not go to Rome. This too was a tour with political views, not as an artist. He published an account of his journey at Lübeck in 1838, under the following title: — 'Reise durch die östlichen Bundesstaaten in die Lombardie und die italienische Schweiz, etc.' He died of consumption in Lübeck, in 1838, in the forty-ninth year of his age. His name — Ueber die Beiläufigkeit der Colonen im Neuen Toccana, aus den Urdenken — Hamburg, 1830. In 1841, however, after a fifth visit to Italy, to Venice, in the previous year, he returned to his more genial subject the history of art, and published in Leipzig an inquiry into the invention attributed to Flängeur of printing with engraved plates on damp paper—Untersuchung, dass Maso di Flangeur Erfinder des handgeschweifter Metallplaten auf getrocknetes Papier abzurudern. This was his last labour in the history of art, and his last poetic production of this class was — Raphaels Lehr-und-Wanderjahre.

In 1841 he purchased a house in Lübeck intending to end his days there, and he fitted it up according to his own fancy. The winter of 1842 he spent in Berlin, and he was then attacked with the consumption. The class — he was removed in the spring to Lübeck, where his physician recommended him to visit the baths in Bohemia; he accordingly set out, but being too ill to proceed he remained at Dresden, where he died of apoplexy in July, 1842, in the sixty-fourth year of his age.

Rumohr's last literary production was a preface to — Kampf Demokratischer und Aristokratischer Principien zu Anfang des sechszehnten Jahrhunderts, Lübeck, 1843. It is a translation from three papers presented to him by Professor Ahlmeier of Brussels. His 'Italienische Forschungen' will remain as a monument of his judgment and industry when probably nearly all his other works are forgotten. It is one of the best documentary works in the literature of art, and at the same time abounds in critical and theoretical reflections; it is likewise a work of great interest, though there may be different opinions about the correctness of Rumohr's theories. The two first volumes are upon modern art in Italy generally, from its origin to its decline in the 16th century, which is distributed under fourteen distinct heads; many errors in Vasari are corrected; much obscurity of the 12th, 13th, 14th, and 15th centuries is cleared up by authentic documents; and various false notions concerning the development of art are dissipated by critical reflections: the third volume is under two heads only, which treat chiefly of Raphael, and the architecture of the 15th and 16th ages.

(Kunstblatt, 1844.)

RUNCIMAN, ALEXANDER, an eminent Scotch painter, was born at Edinburgh in 1724. His father was a weaver, and he made coloured sketches in the fields as early as his twelfth year. At the age of fourteen he was placed in the studio of Johann Christoph, John being compelled sometimes to work as a farmer and an independent landscape painter. When only nineteen years of age he set up as an independent landscape painter in Edinburgh, but it seems the people of Edinburgh, like those of the other places, though lavish of their praise were very cautious in their purchases, and Runciman had the gratification of dwelling on his own pictures, for they were left on his hands. This state of affairs continued for about five years, when in 1749, for the first time he exhibited his pictures in Edinburgh, and though he had more ability for this line of art his fortune seemed to have been very little if at all improved. In 1756 he visited Italy, and at Rome made the acquaintance of Fuseli. Their tastes in art were very similar: both were absorbed by what is termed the sublime, and both were alike wild and extravagant in their execution. 'They were,' says Allan Cunningham, 'rivals in that unbridled licence of imagination, which introduced an air of irresponsible and considerate extravagance into the sublimest and stornest subjects on which they employed their pencil.' Runciman remained five years in Rome, and when he returned home he carried with him a knowledge of the introduction in which he had been living, the following passage: 'I send this by the hands of Runciman, whom I am sure you will like: he is one of the best of us here.'

He arrived at Edinburgh in 1771, a fortunate time for him, for Parravilion, the director of the new academy of the arts which had been established at Edinburgh in 1769, had very recently died, and Runciman was appointed to fill his place, with a salary of 120l. per annum, than a sufficient income in those days. He was considered one of the most original of his time, and was patronized by Sir John Clerk, of Penicuik, and Robert Alexander, an Edinburgh merchant. The former employed him on a great work at Penicuik, suggested by himself, neither more nor less than the whole of Scotland. The work comprised with twelve great compositions from Macpherson's Ossian, which at that time was believed in Scotland to be authentic.

The subjects are—Ossian singing to Malvina; The Valour of the proposed attack; The rigorous justice of the king; The time of Hunting of Catholda; The finding of Corban Carlops; Gobletosse mourning over Lamberg; Oina Morval; Cormac attacking the Spirit of the Waters; The death of Cormac; Scandinavian Witches making Incantations; and Finnegans engaging the Spirit of Loda. The picture of Agonacea is reckoned the best.

One cannot but respect the enthusiasm of the painter of such a series as this, but as works of art they are extravagant in treatment and in composition, and incorrect in design. While engaged in this work Runciman painted also — The Ascension — on the ceiling over the altar of the episcopal chapel in the Cowgate of Edinburgh. He painted also — King Lear; Andromeda; Nausicaa and her Nymphs surprised at the Water Side by Ulysses; and Agrippina landing with the Ashes of Germanicus.

Runciman died in Edinburgh in the year 1772 and exhibited some picture there, but all that is remembered of him, says Allan Cunningham, is that he took up his quarters with the widow of Hoghurst, who was in those days reduced to let lodgings for fourpence a head. Runciman died suddenly of a fit of apoplexy, West Nicholson street, October 21, 1785, in his forty-ninth year. He had contracted an illness while painting the Penicuick cupola, being forced to lie much on his back, and to this is attributed the shortness of his life.

Runciman's best works are his sketches; his faults are only multiplied in his pictures. The most offensive of his peculiarities of design is his huge length and uniformity of limb, the glaring defects also of the works of Fuseli; he was also invariably extravagant in his attitudes, and was conventional, mannered, and unnatural in his draperies. Indeed, to the precise and academic taste, the works of Runciman will, says Allan Cunningham, be ranked among the crude attempts of arrogant immobility. In execution he was least defective in his colouring, but in composition he was ever ready, and his invention was grand and fertile. There are few etchings by him from his own designs; the best is considered — Siggurna weeping over the Heart of Tancred.

He is said to have been lively and agreeable in conversation; Hume, Robertson, Lord Kames, and Monboodho were among his associates.

(Contribution of Eminent Scotch Painters, &c.)
after whom he engraved, besides some others, an excellent plate of Jupiter and Leda; he also etched some plates after Ondry while at Paris, illustrating the fables of Fontaine.

Soon after his return to England Ryland was appointed engraver to George I and was made a companion of the Royal Academy in 1743. He engraved two portraits of George III. after Ramsay, and one of Queen Charlotte holding the Princess Royal on her lap after Cotes; it was one of Cotes's principal works. 'It is very clear,' says Sir Robert Smirke, 'that Ryland was a very considerable engraver, and that he had a just claim to a place in the annals of art.' Among his engravings, which were numerous and varied, were a number of portraits, landscapes, and historical scenes.

Ryland's life was one of hard work and continuous effort. He was a prolific engraver and produced a large number of works during his career. His work was highly regarded and he was recognized for his contributions to the art of engraving. He was a member of the Royal Academy and received several honors and awards throughout his career.

Ryland's work was widely circulated and his engravings were sold in many cities and countries. He was successful in maintaining a steady income from his work, and his engravings were highly sought after by collectors and art lovers.

Ryland's engravings were not only of high quality, but they were also highly detailed and accurately reproduced. He was able to capture the essence of the original paintings and create works that were true to the original art. His engravings were highly sought after and were considered to be some of the finest in the world.

Ryland's work was highly respected and he was considered to be one of the leading engravers of his time. He was a man of great accomplishment and his contributions to the art of engraving will be remembered for many years to come.
St. Francis, St. Cecilia, and Chastity burning the Arms of Cupid, by Guercino; Bathsheba, by Boucher; Jacob persuaded to send Benjamin with his Brethren into Egypt, by Van der Vaart; Cellini; Pyramus and Thisbe, by Rembrandt. Besides these there are drawings by the following masters:—Baccio Bandinelli, Battista Fiastra, Perino del Vaga, Bernini, Andrea Sacchi, Stefano della Bella, Bolognetti, Giuseppe Palma, the younger, Giorgio Massimiani, Cam. Proccaci, An. Carracci, Schidone, F. Mola, Eliz. Sirani, L. Cambiaso, S. Rosa, Jan Breugel, and P. Wouwerman. He engaged for the design of a plaster statue, for P. d'Arcontas, Van- den-Crijper, Boucher, Ramsay, J. B. Oudry, and others.

RYSBRACK, MICHAEL. The date of the birth and the birth-place of this distinguished Flemish sculptor are different. He was born at Lubeck, or Bonn, where his father, a road-cutter, published the 'Century of Drawings,' &c., who was well acquainted with him, states that he was born at Antwerp June 24, 1693. He was the son of the landscape-painter Pieter Rysbrack, who, after he had given his son some instruction in design, placed him in 1706 with the sculptor Michael Vander Vorst, with whom he remained six years.

In 1720 Rysbrack came to London and distinguished himself for his small models in clay. He was the first sculptor who was extensively employed in England, and he spread a general taste for the art over the country by his fine monumental works. His progress in London was at first slow, and he found a contracted notion of the art in the north of England. He was for some time engaged with Gibbs, who contracted with the original parties for monuments, for which he, on his part, contracted with Rysbrack, greatly to his own advantage. When Gibbs received the Lord Oxford monument 100L, each for the statues on Prior's monument in the south transept (or Poet's Corner) in Westminster Abbey, while he gave Rysbrack only 50L each. Rysbrack, however, soon became aware of his own merits and shook off all dependence on Gibbs. Engagements crowded upon him, and there was not a work of sculpture of any consequence undertaken in England that was not entrusted to Rysbrack. When men found, says Walpole, that there was a sufficient supply of fine statues, the taste for monuments was much improved and greatly spread. 'Our monuments until Rysbrack's time,' says the same writer, 'had depended more on masonry and marbles than on statuary. Gothic tombs owed their chief grandeur to rich canopies, fretwork, and abundance of small niches and trifling figures. Bishops in cumbent attitudes and cross-legged Tompalls adored no grace not required any. In the reigns of Queen Elizabeth and King James I. a single figure reclining at length on the elbow in robes or serjeant's gown, was commonly overwhelmed and surrounded by diminutive pillars and obelisks of various marbles; and if particularly sumptuous, of alabaster girt. Gibbs, in the Duke of Newcastle's monument in the Abbey, seems to have had an eye to that kind of tasteless taste. From the reign of Charles I. and the Commonwealth, all things of framing charge generally satisfied the piety of families. Bird indeed bestowed busts and bas-reliefs on those he decorated, but Sir Cloudesley Shovel's, and other monuments by him, made men a taste of such honours.' ('The abilities of Rysbrack,' continues Walpole, 'taught the age to depend on statuary for its best ornaments, and though he was too fond of pyramids for back-grounds, his figures are well disposed, simple, and great.'

Rysbrack, unlike most of the artists of his age, studied exclusively nature and the antique; he had no respect for the works of his great countryman Rubens, and those of Rembrandt he would not look at. In which he was of course attacked wholly by the feelings of a sculptor, form and character being his exclusive study. He was a most industrious sculptor. Fine works are to be seen by him in many parts of France, in St. Petersburg, in Wembly Palace, at Stourhead, and at Bristol. In a few sculptors' workshops there has been more activity than was there in those of Rysbrack in Veres-street, Oxford-street, during about forty years of the height of his art. The poet, though entirely through his successful rivals Scheemaker and Roubiliac, his occupation sensibly diminished.

Rysbrack's busts were very numerous, and include those of all the great men of his day. His first great public work was the bronze equestrian statue of William III., which was made for the city of Bristol, and erected in Queen's Square in 1733. Scheemaker also competed for this statue, and his model was thought so much better than Rysbrack's, that 50L. was rejected for the design of Rysbrack, who received 3000l. for it; Walpole says 1800l. The monument to Sir Isaac Newton in Westminster Abbey, which was executed in 1735, was of a design by Kent. One to Mrs. Oldfield, in the cloisters, in the year before, was apparently his first independent monument in the Abbey.

In 1739 he finished a colossal statue of George II. for the parade of Greenwich Hospital, at the expense of Sir John Jennings, the then governor: it was cut out of a single block of marble weighing eleven tons, which had been captured from the French at Blenheim. In 1741 he finished the statue of George II., which was in the old Royal Exchange, London. He obtained however more reputation by his monument to John Duke of Marlborough and his duchess in the chapel at Blenheim; and among the distinguished letters Rogers, who died young, supported by Fame and History; in the lower part is a baso-relievo of the surrender of Marshal Tallard. At Blenheim also, in the library, is a beautiful marble statue of Queen Anne; it was erected in 1726.

In Christ Church College, Oxford, there is a statue of Locke by Rysbrack, which is in the 'Oxford Guide' erroneously attributed to Roubiliac; it was made in 1787. This college contains also some busts of distinguished members by Rysbrack. Besides what have been already mentioned there are the following monuments by him in Westminster Abbey:—

To Admiral Vernon, and Robert Kane, governor of Jamaica, in 1720, in the north aisle; to John Friend, M.D.; and John Methuen, in the south aisle; to Sir Godfrey Kneller, in the nave; to John Gay, Nicholas Rowe, John Milton, and Ben Jonson, in the south transept, near Poet's Corner; and one to Daniel Fultene in the cloisters.

The erection of Shakspeare's monument by Scheemaker, in Westminster Abbey, is said to have greatly obscured the reputation of Rysbrack: but it only stimulated the industry of this sculptor to make still greater exertions. This dread rivalry was the cause of his making his Palladio, Inigo Jones, and Fiammingo, at Chiswick, and subsequently his masterpiece, the Hercules, at Stonor Park, which is said to have cost several Gold Hours. This Hercules is a species of historical figure, a record of the English gymnasia or amphitheatre for boxing, an institution which was put an end to, as the principal gym- nasiasts generally ended their career by being hanged. The figure was made for Henry Hoare, Esq., who built a temple expressly for it. It is of the heroic size, seven feet high, and cost Rysbrack three years labour. The head is copied from the Farnese Hercules; the limbs are taken from several different English freemasons of this gymnastic amphitheatre. 'The arms,' says Walpole, 'were Broughton's; the breast a celebrated coachman's, a bruiser; and the legs were those of Ellis the painter, a great frequenter of that gymnasium.'

There are many other statues by Rysbrack—as a Flora, from the antique, at Stourhead; the Duke of Somerset, at the Duke of Buckingham's, and that of Bridgewater, at Richmond; the Duke of Granby and Lady Gurney; Charles Duke of Somerset and his Duchess, in Salisbury Cathedral; Sir Hans Sloane, in the botanical garden at Chelsea, and his bust in the British Mu- seum; Lady Folkestone, Colybut, Earl; Lady Beaufort, Derbig; the second, third, and fourth Dukes of Beaufort, at Badminton, Gloucestershire; Dr. Radcliffe, at Oxford; John Willet, Esq., Merly House, Dorsetshire; a statue of Charles I., for George Selwyn; and the following busts:—Pope, Gibbs, Sir Robert Walpole, Duke and Duchess of Argyle, Lord Bolingbroke, Wootton the landscape-painter, Martin Folkes, Ben Jonson, Butler, Milton, Cranwold, the heads in the Hermitage at Richmond, and those of the English Worthies in the Elysian Fields at Stowe: he made also a good bust of himself. Notwithstanding his industry, Rysbrack was not rich, and when at the age of seventy he gave up his pro- fession, his former friends failed him. Besides his remaining works and his collections of prints, pictures, drawings, marbles, casts, models, &c., including a large collection of his own drawings, which, says Walpole, were conceived and executed in seven years, and though they are hung in the adornment of the last three years of his life was in making such drawings in bistre, and many were sold at the two auctions of his effects which took place after his death. He died January 11, 1770.

SABUNEA (named by De Candolle, in honour of Joseph Sabine, F.R.S., long time Secretary to the Horticultural Society of London), a genus of plants belonging to the natural order Leguminosae. It has a cup-shaped campasule with a truncate, nearly entire border, a papillose-coriaceous corolla, with an obn Johnston, rather shorter than the vexillum. The stamens are diadelphous, the free one and four others half as short as the rest. The style is filiform, glabrous, and is anastomosed with the stamens. The legume stipitate, compressed, linear, elongated, many-seeded, mucronate by the style. The species are unarmed West Indian shrubs, with abruptly pinnate leaves, smooth mucronate leaflets, and one-flowered fascicled pedicels.

S. floridea has its leaflets in 8 or 9 pairs, elliptic oblong, the flowers rising before the leaves. It is native of the American Islands of St. John, Krabben Island, and St. Thomas. The violet flowers are considered poisonous.

S. duchesii has its leaflets in 10-12 pairs, elliptic oblong, the flowers appearing after the leaves. It is native of Martinique and Porto Rico.

SACCHOLACTIC ACID. [Chemistry—Mucic Acid, P. C. S.]

SADAI. [SAADI, P. C.]

SAFEET-KALVE. [Zonax-Equus, P. C. S.]

SAGACIA, a genus of plants belonging to the coal-formation, (Brongniart.) It includes species ranked by Sternberg as Lepidodendron.

SAGENOCRINUS, a genus of fossil crinoids. (Asin.) Family of the Crinoids of Dudley.

SAGENOPTERIS, a genus of fossil ferns. (Prent.) It occurs in the shales of the Yorkshire coast, and includes part of class of Lycopodiaceae.

SAGRABA. [SPADA, P. C. S.]

SAHARUNPOOR, a district in the province of Delhi and presidency of Bengal, in Hindostan, formerly extended northward from the city of Delhi as far as the Sutlej, and which form the northern limit of the immense valley through which the Ganges flows. The Ganges and Jumna, north of the city of Delhi, run nearly parallel to each other at a distance of about 50 miles, and the district of Saharanpur occupied the doss, or flat space, between them. The soil of the whole of this space is exceedingly fertile, producing grain of all kinds, sugar, cotton, indigo, and tobacco. Madjeep or the Hindoo obtained possession of it in 1788, and it was held by the Hydriat till 1803, when it was given up to the British. In 1804 it was formed into two divisions, Northern Saharanpoor and Southern Saharanpoor, with a civil establishment for each; but the arrangement has been since modified, and the greater part of Southern Saharanpoor has been included in the district of Merut. Of the district of Merut, or Southern Saharanpoor as it is still sometimes called, the chief town is Merut, in 29° 55' N. lat., 75° 45' E. long. Of the district of Northern Saharanpoor the chief town is Saharanpur, in 29° 59' N. lat., 77° 35' E. long., and about 90 miles, direct distance, N. by E. from the city of Delhi.

SAILORS. [SAIT, P. C. S.; BRAMH, P. C. S.]

SAILORS. Accidents involving serious loss of life and property are continually occurring from the inability of ordinary sails to resist violent gusts of wind. The sails of a ship (Saiz, P. C. S, p. 281) usually consist of several widths of canvas sewn together side by side, with the seams arranged vertically; and the principal strength which they have to resist tearing arises from cords sewn along the edges of the sail. If these give way, or if from any accident a tear is commenced, the rupture frequently extends at once along the whole length of the canvas, and the sail is thereby, in neutral phrase, to turn into rubide. To provide a remedy for this formidable evil, Mr. Archibald Tait patented in 1844 an improved kind of sail, which, from their fitness to resist violent winds, he terms Storm-sails. These are made in the usual manner, and subsequently strengthened by sewing to their surface a number of canvas bands about an inch broad, with cords woven in them, such bands being secured at their ends into the boltropes, or cords forming the boundaries of the sail, and carried diagonally across the surface of the sail at an angle of 45° with the seams, and at a distance of about three feet from each other. Two sets of bands are used, crossing the sail in opposite directions, one set being attached on each side of the canvas, and the distance of the bands from each other is so adjusted with reference to the width of the canvas, that the points where the two sets cross each other may fall upon the vertical seams. By this simple contrivance the strain is so equalized as to render tearing less probable than with an ordinary sail; while, if any injury be inflicted, the rent is confined within the narrow limits of one of the diamond-shaped compartments into which the sail is divided by the principal bands. In ordinary cases it is proposed to apply these bands not to new sails, but to such as are half-worn; and the patentee states that such sails may be thus protected at one-fifth of their original cost. For sails of the same size a similar improvement in another direction is at present under the test of experience, have testified their hearty approval; and it is suggested by some that its adoption may lead to the use of lighter canvas than would be safe with sails of the ordinary variety. (Salter, P. C. S., p. 14.)
cient to make the extra cost of the protection only one-tenth instead of one-fifth.

SAINT GEORGE, SAINT MARY, SAINT MICHAEL, etc. (GEORGE, ST.; MARY, ST.; MICHAEL, ST.)

SAINT HILAIRE, GEOFFREY ETienne, was born at Etampes, in France, the 15th of April, 1772. He was destined by his father for the church, and received the appointment of a schoolmaster, but, however, sent to the college of Navarre, where Briason lectured on experimental philosophy, and under him he acquired a taste for the natural sciences. He first devoted himself to medicine, and, in 1795, became associated with Cuvier at Paris; he studied very diligently, and in 1798 was appointed subcurator and demonstrator of the Natural History cabinet, in the Jardin des Plantes. He was subsequently appointed professor of anatomy and physiology in the faculty of sciences in 1808. He was sent by the government on a scientific expedition to Portugal in 1808. In 1815 he was returned as a member of the Chamber of Deputies for his native city of Etampes. He died at Paris in July, 1828.

Geoffrey St. Hilaire was one of the most assiduous cultivators and ablest exponents of what is called philosophical anatomy. The idea on which this department of science was founded was that the parts of animals were developed and applied to zoology and comparative anatomy during the latter part of the last century. It was, however, amongst the rich collections of the Jardin des Plantes, and the activity and zeal of such men as Lamarck, Cuvier, Toumey, Dumas, Valencienne, Serres, and St. Hilaire, that it received its most important applications and its greatest development. The fundamental idea of this system is the unity of the composition of the parts of the animal. The result of this is that each unity is capable of expression in a few simple laws. What, in fact, might be predicated in botany of the various parts of a plant by a knowledge of the structure of the leaf, might, in the same manner, be applied to animals by a knowledge of certain fundamental parts of their organisation. Thus Geoffrey St. Hilaire, amongst his other labours, established the fact that the numerous leaves of the head of the fish, and by consequence those of the higher animals, were transformations of the simple vertebrae; and that the laws of development which applied to the one applied to the other.

These views, equally applicable to every organ of the body, were given by Geoffrey St. Hilaire, in a work published in 1818, entitled 'Philosophie Anatomique,' which was illustrated with an Atlas of folio plates. He also published several papers on the principles of the philosophical anatomy. In 1828 a small work appeared, as an introduction to the lectures delivered on natural history in the Jardin des Plantes on the principle of the unity of organic composition, with which he was connected, entitled 'Philosophie de l'Organisme,' 5vo. Although previous to the time of Geoffrey the morphological idea lying at the basis of philosophical anatomy had been applied to the explanation of the phenomena of abnormal forms of animals, just as it had been of plants, yet the subject had not been fully developed. In 1822 he published his great work on the anatomical philosophy of human beings. These beings, which had formerly been regarded as mere accountable freaks of nature, were now found to be the result of the action of fixed laws, and their various forms susceptible of the strictest classification. This work contained a new classification of monsters, with a description of the variations of their different forms; and a history of the various causes supposed to produce them. It also comprehended some new views on the nutrition of the fetus, and an accurate estimate of the phenomena attending the formation and growth of the embryo. It was the result of two years' labour, in which the author pointed out the fact of a unity of composition in the reproductive apparatus of the two sexes in birds and mammals.

St. Hilaire's work, in which St. Hilaire contributed to the various departments of natural history would be very long. There is scarcely a branch of zoology to which he did not successfully apply the great principles of his anatomical philosophy. Amongst the works published during the present century that do not bear testimony to the great influence he has exerted. At the same time the views held by the school, at the head of which Geoffroy St. Hilaire may be justly placed, have led to great controversy. Fully as Cuvier was impressed with the importance of Geoffroy's works, he opposed him in some of his conclusions, and this led to a controversy which developed, in these inquiries, a theological element. Geoffroy was convinced of final causes, as being in opposition to the theory of a unity of composition. In his philosophy he states that he knows nothing of 'intentions' or 'objects' in creation; and when he says that man is an animal he rejected that there were 'no animals which had a part to play in nature.' This controversy has recently, in this country, assumed a popular form; but it is obvious, from the use made by the supporters of the one side, as well as by the other, of the principles of the 'Anatomical Philosophy,' that this theory is not incompatible with their views.

A complete edition of the works of Geoffroy, has been published in France under the title of 'Professional Studies of a Naturalist,' in 42 volumes. Etienne Geoffroy St. Hilaire has left behind him a son, Lidore, now Professor of Zoology at Bordeaux, and formerly at Paris, who has successfully cultivated the favourite science of his father. A complete list of Etienne Geoffroy St. Hilaire's works will be found in Callisen's 'Medicinisch-Schriftenlektor Lexicon.'

SALENIA, a genus of Echinoidea, remarkably profuse of species in the forms of the echinoderm class. It was named by de Saules, de Francis, Saint, was born at the Castle of Sales, near Anneye, in Savoy, on 21st August, 1857. His parents, the Count and Countess de Sales, are described as having been of a religious and ascetic character. As a child he was placed under the care of the Jesuits. He soon became a proficient in rhetoric and philosophy, and, at the same time, he did not neglect those arts which are calculated to adorn an intercourse with society, though, in his formative years, he had obeyed the wishes of his father than to have followed his natural inclination. He remained in Paris till 1858, when he was sent to Padua to study civil law under Guay Fancourt. At Padua he formed strong attachments and made friends which increased into friendship, with the Jesuit Antonio Pasoevino, under whose spiritual direction he placed himself. His success at Padua exceeded the expectation of his friends, and, at the age of twenty-four, he left that university with a high reputation for learning and piety. He afterwards spent some time in Italy, and made a pilgrimage to Notre Dame of Loreto. On his return to his native country, he found that his father had obtained for him the appointment of Counsellor in the Senate of Chambery, and was desirous of uniting him with a rich heiress, whose fortune would enable him to enter the Church. The mind of Francis, for a long time directed towards theological pursuits, had however gradually acquired a disposition which could only be satisfied by an entire devotion to them, and he was anxious to enter the Church from his childhood to yield obedience to his father's wishes, he feared to make him acquainted with his desire. In this difficulty he consulted a relation, Louis de Sales, who was canon of the church of Geneva, and through his mediation the Count de Sales was induced to abandon his favourite project, and allowed his son to devote himself to the ministry of the church. After receiving the first orders he was permitted by the bishop to preach. The greatest success attended his first efforts in pulpit oratory. He possessed, indeed, all the qualities calculated to gain the attention of his hearers; a voice powerful and pleasing, an animated and persuasive action, and a ready wit and humour. He was himself deeply convinced of the truths he was advocating, were heightened in their effect by a strikingly handsome person and a mild and modest demeanour. In the fulfilment of his pastoral duties he was not less capable, and was able to the priesthood, with rather a childish expression, pleased at first sight; little children in their nurses' arms could not take their eyes off him. He was equally delighted with them, and would take his hands, and say, 'This is my little family. The children ran after him, and the mothers followed them.' (Michelet, 'Priests, Women, and Families, translated by Cocks.)

Vor. II. — 3 U.
We may now present him exercising these qualities in a larger sphere and applying them to the conversion of those who differed from him in religious faith. The better to understand the peculiarly difficult nature of the mission with which he was intrusted it will be necessary to give some account of the circumstances of the time. The city of Genoa, having pronounced the authority of its bishop and that of the Duke of Savoy; it was an independent republic and the stronghold of the Calvinistic party. It had become possessed of the antiestates due to Louis XIII., and the territories of Gex, Terni, and Gaillard; coincident with these changes was a substitution among the inhabitants of the creed of Calvin for the faith of Rome. In 1600, Charles Emmanuel Duke of Savoy, pretended to exercise this antiestates portion of his duchy, and his first care was to attempt to bring back the inhabitants to their former religion. (De Tho, Hist. Univ., 1. aee.) For this purpose he applied to the titular bishop of Geneva, Claude de Granier, to send missionaries over the conquered country. Francis de Sales, and his relation Louis, the canon of Geneva, were among the first to undertake an enterprise in the prosecution of which much opposition and some personal danger were to be apprehended.

On the 9th September, 1594, the two missionaries arrived at the frontiers of Chablais, where they dismissed their servants and equipages and determined to travel on foot, in order more easily to render themselves visible to the inhabitants of the town of Tomon, the capital of the Chablais (CHALILA, P. C.), which contained only seven Roman Catholics, was the first place in which they exercised their mission; the fruit of it may be seen in the fact that the town, the next year, under the name of Chablais, was attached to the church of the Exarch, in the church of St. Hippolytus in that town. But the most important object of this mission, in view was the conversion of the adherents of the Calvinistic party. To effect it he first solicited an interview with Theodore de Beza (BEZA, P. C.), who was then fast sinking under the weight of age and infirmities; several conferences took place between them at Geneva; and the result of them is very differently related according to the religious persuasion of the narrators. Whatever change however took place in the mind of Beza through this interview is none that Francis could possibly be accompanied by no public profession. Michelet, without however citing his authority, remarks, that the Roman Catholic missionary added to his spiritual inducements the weight of temporal advantages, and made an offer of a pension of 4,000 crowns if he would conform to his church.

On the return of Francis to Annecy, in 1596, he was appointed coadjutor to Claude de Granier, the bishop of Geneva, with the title of Bishop of Nîmes in perpetuity; this dignity he for a long time refused to accept, and only yielded on the earnest solicitation of the pope, Innocent X.

In 1602 he visited the court of France for the purpose of obtaining permission from the king, Henry IV., to pursue his missionary labours in the territory of Gex, which had been given up to France by a treaty of peace concluded between Henry of Navarre, son of Louis of Savoy, and Charles of France, which he preached in the chapel of the Louvre, is said to have created considerable sensation, and to have become the means of recalling several of the most influential of the Calvinistic nobility to a belief in their antestes faith. The king, desirous of retaining him in France, made him the offer of the first bishopric which might become vacant and the immediate enjoyment of a considerable pension. These offers however he declined, declaring that his being in France was to be permitted only on condition to live and die among those whose Providence had intrusted to his care.

On his return to his native country, after a residence of nine months in Paris, he was, by the death of De Granier, a prelate who appears to have been worthy of so illustrious a colleague, appointed to the bishopric of Geneva. He prepared himself by a close retirement of twenty days at the castle of Annecy, and a plane of dedication to this important office. In this retirement he framed for himself a rule of life by which he was in future to be guided; the details of it are given with elaborate minuteness in his biographer. (Venturi, Dei, Hist. Univ., iv. p. 313.) We shall only extract the passage which shows that he considered the faithful fulfilment of duty of greater importance in the sight of God than the exercise of bodily mortifications or the display of an ascetic

* * *

**La voix politique de Sis** says Bayle, "n'a point tellement tarie l'an 1699. Les organes de la France, qui en font un dessein, ont été sans compter. L'œuvre de la Réforme a été, comme celle de toutes les œuvres de l'homme que l'on fait forte qu'elle doit, et qu'avant d'explorer avait fait profession de la dévotion. (Bayle, Dict. Hist., art. "Sis"). See also Jacob Epin, Hist. de Genève, liv. v. p. 313. (Urencht, 1668.)
The claims of St. Francis de Sales as a devoted servant of the church have never been disputed, though they have been differently esteemed and represented. Humility and zeal were the essential elements in the saint's character. He refused to be promoted to the position of superior, and he was mindful of the wishes of others. Between him and Fenelon, a closer comparison might perhaps be made than with any other saint to be found in the Church. As a diplomatist, they possessed in common noble birth and a high station, with the tone and manner which these advantages are calculated to produce; the same talent in captivating the attention and winning the sympathy of the minds with which they came into contact. In the discharge of their pastoral duties they were alike successful, and by the use of the same means, a careful adaptation of advice to the temper and disposition of the advised. While, however, it must be admitted that Fenelon was a far more perfect diplomatist, and a theologian, he was probably inferior to his genuine disinterestedness and the practice of self-denial: he loved rather to labour among the rich and great than, like De Sales, to abandon the court in order to mingle with the crowd of the poor and suffering. Fenelon, it is true, performed with zeal those essential duties of a pastor when he was banished to his diocese; De Sales was continually separating himself from the court in order to perform in a manner which is perhaps more perfect to posterity. [FENELON, P. C.]

The most known of his writings, which are not very numerous, have been noticed in this article; the best edition of them is that of Paris, 1841, 2 vols. folio.

The impression which Bishop Butcher made in the church is not less evident in his writings, and the same is true of Bishop Butler, Charles Augustin De Sales, Henri De Maupas, Bishop of Evreux, Le Père Goulau, M. De Bussy Rabutin, and the Jansenist Binet. See also Alban Butler's Lives of the Saints; Moretti, Dict. Histoire des Actes et des Martyrs; P. M. Desaulles. [SA.MARA. SIMRISH, P. C.]

SAMEN or SEMIEN MOUNTAINS. [ADAMS, P. S.]

SAMENESS or IDENTITY. This term is generally applied to what is called personal identity, or the sameness of a living and intellectual being, as man. There are some remarks on this subject by Bishop Butler in his ' Dissertation of Personal Identity.'

The sameness of objects which are external to a man consists in the perception of a variety of circumstances as to these external objects and at different times, from which arises an opinion of sameness in a certain sense. A man sees a tree growing in a certain place, and he may have remembered it for many years. But in the mean time the tree may have increased a hundred-fold in bulk, and therefore its substance is not the same as that of the tree which he first saw there; and besides this, there may not be a single particle of matter the same in the tree at two remote times of his observation. The tree then is by the supposition not the same in a strict sense; but in a loose sense it is different. A man may no more believe that all the change that the tree has undergone belongs to some other tree, than he can believe that the growth of his own body belongs to another being than himself.

When sameness is applied to a living and intellectual being, it includes both the matter of the body and something else. A man can have no doubt that his body is not entirely the same in youth, in middle age, and in old age. He can view his body as he does any thing external, and he has a belief that it undergoes changes, and is therefore not the same in the strict sense. But yet he considers himself the same person; person here including something besides the body, whether it be something a property of an organized body or something else. 'The ground of the doubt,' says Locke, as quoted by Butler, 'whether the same person be the same substance, is said to depend on the consciousness of four or our own existence, in youth and in old age, or in any two successive moments, is not the same individual action, i. e. not the same consciousness, but different successive consciousnesses.' Butler's answer to this vague talk is sufficiently good. More may be said. How is consciousness of our personal identity, or if this form of words be objected to as a way of begging the question, how is the thing called 'consciousness of our existence' at any two successive moments of time? It is supposed that the consciousness is one and the same always; and if it is allowed that there is in man a belief that he is at different times the same being, in some sense which he cannot otherwise explain than that he feels that he is, it follows that this consciousness of personal identity is one indivisible thing, that it is as continuous as the personal identity itself which it presupposes. Nor is it any objection that such a personal identity may be materially impaired by disease, and he may lose the exercise of his reason and recover it; or an accident may befall him, which for a time robs his body and mental powers inactive, though he may finally recover both. On his recovery he does not doubt that as his personal identity is that of a person that he was before his illness or accident, and therefore his consciousness is one. The division of consciousness by successive times, corresponding to certain external signs, and the supposition that successive succession of consciousness in personal identity, is to confound things that are unlike, and to apply a measure to both that does not fit one of the things. Every person, says Butler, is conscious that he is now the same person as he was at the time his consciousness reaches.' This cannot be disputed. It is a bare fact that this consciousness does exist in us. We have not this consciousness from the time of our birth up to manhood and old age: it does not go further back in its particular manifestations than our remembrance does; yet we doubt not that we, the man, were once that particular child of our parents rather than any other child of these parents or of any other parents. But this belief is derived from evidence our consciousness in its particular manifestations does not extend farther back than our remembrance. Yet remembrance does not make personal identity, as Butler remarks: 'Consciousness of personal identity presupposes, and therefore is mere consciousness of personal identity, any more than knowledge, in any other case, can constitute truth, which it presupposes.'

The remembrance of particular things is a very different thing from that consciousness of personal identity. When this consciousness begins, when it ends, how its activity is suspended, we know not: but we know that it is a law of our nature that, in the ordinary state of a man's bodily and intellectual faculties, he has remembrance whatever it may be and however it may arise, whenever he reviews certain acts of his own or events in his life, that he be the perceiver, and no other person, is the agent or is the person affected by these events. The remembrance then merely makes the consciousness of personal identity active; and this consciousness of personal identity is not constituted of the remembrance of different acts or events, but is as permanent and uninterrupted as the animal life itself, which nobody supposes to consist of successive lives, but to be one life.

And it should be observed that the question of personal identity only arises upon the suggestion of the memory. Every man all through his life feels that he is in some sense or in some way, which he expresses by the term 'I.' And he is never without this present consciousness of existence. There is therefore an uninterrupted consciousness, which, as already observed, is one, and not divisible by a measure of time. The remembrance is on certain occasions an abstraction or a mere consciousness or act of memory. Even if any event in his own life, is a present act, and the consciousness of such present act of memory accompanies the act of memory as it does any other present act; and as the act of memory is retrospective, so is the consciousness of a memory retrospective, but only incidentally, according to the nature of the act. The memory merely directs the conscious agent to an act of the kind called passed, and to a passed act of such a kind that the consciousness of sameness in the agent is inseparable from the notion of the act that is remembered.

SAMULUS, a genus of plants belonging to the natural order Primulaceae. It has a 5-parted calyx, its tube adhering to the lower half of the germen. The corolla is salver-shaped with a short tube and a 5-parted limb with interposed converging scales. The stamens, 5 in number, are inserted near to the base of the limb of the corolla. The capsule is half covered by the persistent calyx, many-seeded, and opening with reflexed teeth.

S. edwardi, brookweed, has obonate or roundish blunt leaves, the upper leaves blunt with a point, the middle leaves linear, flowered ultimately elongated, the capsules subglobose. It is found in damp, watery places in Great Britain. [Linley, Vegetable Kingdom; Barnett, 'Outlines of Botany for School and College Teaching.]

SAND-EL. [AMMODYCES, P. C. S.]

SANDARAC. [THUJA, P. C.]

SAPIUM, a genus of plants belonging to the natural order Euphorbiaceae. The flowers are in compound umbels, and the capsules are 3-coccous. [B.]

S. anacampyrum is a tree 30 feet high, with oblong lanceo-
late, acute, serrate leaves, with an internode of larger and rounder teeth, coriaceous, shining, and about 6 inches long. The spikes are terminal, lax, thick, green, and about 6 inches long; the male above, the female below. The calyx of both is dark purple. It is native of the woods of Caratha.

S. indicum has alternate stalked leaves somewhat pendulous, broad, lanceolate, serrate, smooth, and of a deep shining green, from 2 to 4 inches long, and broad in proportion; the stipules small and deciduous. The calyx is 3 parted, the divisions somewhat cordate and expanding. The filaments longer than the calyx, the anthers ovate.

The flowers are at the base of the leaflets and often solitary. The capsule or nut is oval globular, of the size of a nutmeg; 3-celled, 6-valved, thick, and exceedingly hard.

The seed is solitary, affixed by the apex, ovate, and smooth. The juice of this species, like the former, is highly poisonous.

(Lindley, Flora Medica; Burnett, Outlines of Bot.)

SAPONA’RIA (from the Latin 'sapo', 'soap', so called because the bruised leaves are said to produce a lather like soap when agitated in water), a genus of plants belonging to the natural order Caryophyllaceae. It has a 5 toothed calyx naked at the base, 5 clawed petals, 10 stamens, and 2 styles. The capsules are 1-celled, opening at the top with 4 valves. The flowers are red or crimson.

S. officinalia, soap-wort, has fasciculate corymbose flowers, a cylindrical slightly downy calyx, retuse crowned petals, elliptic lanceolate-ribbed leaves, and an erect stem. It is native of Europe, and is found in the south of France, and in Britain, in meadows by rivers and under hedges. The flowers are either single or double, of a rose or pink colour, seldom white.

The double variety of this plant is esteemed as an ornament to the gardens of Venetiae. It was introduced into Britain in the reign of Henry III. In the kitchen, it is used in pots, from the spreading nature of the roots, which extend under-ground like those of couch.

S. vaccaria has panicked flowers, pyramidal, smooth, fine-angled at the root; ovate-obovate leaves; ovate, lanceolate, sessile leaves. It is native among corn in many parts of Europe, particularly Germany, Switzerland, and the Levant.

It derives its specific name from the idea that it increases the lacteal secretion in cows.

All the species of this genus are very ornamental. S. ocy- moides is one of the most elegant plants we have in our gardens, and is well adapted for rock-work. It has red or pink flowers and is a trailing plant. A mixture of sand, loam, and peat is best adapted for all the species, and they are easily propagated by dividing at the root, or by seeds; the young cuttings taking root freely under a hand-glass.

(Don, Gardeners' Dict.; Babington, Man. Brit. Bot.; Burnett, Outlines of Botany.)

SARCOSTEMMA (from σαρκός, flesh, and στέμμα, a crown, in reference to the leaflets of the inner corolla being flesh-colored), a genus of plants belonging to the natural order Capparidaceae. It has a rotate corolla, a corona of double stamens; the outer one cup-shaped or annularcrenated, the inner one 5-leaved, higher than the outer one, with fleshy sepals, which are nearly in his shape, round, flat, and smooth, and the seeds conose.

The species of the genus are natives of New Holland and the East Indies as well as of South America.

S. glaucum, glaucous-leaved Sarcostemma, is a lacerate smooth twining herbaceous plant. The leaves are lanceolate, short-stalked, slightly revolute, membranous, being with the midrib prominent on the under side, which is glaucous.

The umbels are many-flowered between the pedicels, on very long peduncles. The segments of the calyx lanceolate, dilated, and acuminate. The corolla white with a large fleshy annular wavy corona; the segments of the corolla fringed and spreading.

S. Brownii is a twining glabrous plant, with lanceolate acuminate glabrous leaves, and interpetiolate umbels; the pedicels, calyces, and corolla downy; the segments of the corolla ovate, bluish, concave, and glabrous inside; the outer corona an entire narrow ring; the leaflets of the inner corona ovate, bluish, and glabrous a little higher than the gynostegium. The lower leaves are large and ovate oblong; the upper ones becoming gradually narrower with revolute edges; painted with white on the nerves, and greenish blue on the veins.

The calyx is small; the pollen masses oblong, a little constricted, while hanging by short pedicles rising from blackish glands. These flowers thrive by in meadows, pastures, fields of peast, and vegetable mould; cuttings of them root readily in sand, if placed in heat without any hand-glass over them. They should have little or no water when in a dormant state, particularly the tuberous-rooted kind.

(Don, Gardner's Dictionary; Lindley, Flora Medica.)

SAROTHAMNUS, a genus of plants belonging to the natural order Leguminosae. It has a 5-toothed calyx, the upper tip with 2, the lower with 3 teeth. The style is long, curved, thickened upwards, and channelled within. The stigma terminal, capitate, and small. The pod is flat.

S. scoparius, broom. The only British species is a well-known plant, with a stem 2 or 3 feet high, angular, and glabrous. The leaves are ternate or simple, the leaflets obovate. The flowers are axillary, solitary, or in pairs, short-stalked, and large, and red. The pods are brown, hairy at the edges, and have numerous seeds. It is found on dry hills and heaths.

(Babington, Man. Brit. Bot.)

SATURNI'NUS, a name of several Roman jurists.

CLAUDIUS SATURNI'NUS is the name of a Roman to whom two Recipients of Antoninus Pius are addressed (Dig, 20, tit. 3, 1, 5 § 2; 50, tit. 7, § 4); and person of the same name was procurator under the Divi Fratres, the successors of Pius.

He is generally considered to be the author of a work in a single book, 'De Poenis Paganorum,' which in the Florentine Index is attributed to Venenius Saturninus. There is a single extant excerpt from this work in the Digest (48, tit. 19, § 16).

QUINTUS SATURNI'NUS is cited in the Digest (34, tit. 2, § 19, § 7) as the author of a work 'Ad Edictum,' in ten books at least. Whether he is the same as Claudius or not is uncertain.

VENENIUS SATURNI'NUS, a Roman jurist, who is simply called Venenius in the Florentine Index, though in the titles of the Excerpts in the Digest he is often called Venenius Saturninus. The 'De Poenis Paganorum Under Severus, 65' says that he lived under Alexander Severus; but there is some doubt about his period. His writings mentioned in the Florentine Index are, Ten Books of Actiones, Six of Interdicta, Four on the Code of Diocletian, and Nineteen of Stalinopithecus. The book De Poenis Paganorum has been already mentioned.

(Grotius, Flute Jurisconsultorum; Zimmern, Geschichte des Röm. Rechts, Heft 2, pp. 354, 379.)

SAURICHTHYS, a fossil genus of fishes from Axmouth. (Agassiz.)

SAUROCEPHALUS, a fossil genus of fishes from the chalk series of England and America. (Hays.)

SAURODON, a genus of fossil fishes from the chalk series of England and America. (Hays.)

SAUROFIS, a genus of fossil fishes from the oolite and lias terrains. (Agassiz.)

SAURUREA, a genus of composite plants belonging to the sub-order Cynaraceae. The flowers are all hermaphroditic and tubular. The anthers with ciliated setae at the base.

S. ophioides, an annual plant with a white or yellow ovate lanceolate, the upper ones sessile lanceolate, all distantly-toothed, the heads in a dense corymb, the involucres sub-cylindrical, with depressed hairy scales. This is the only British species: it is found in alpine situations.

(Babington, Man. Brit. Bot.)

SAUSMARZ, DE JAMES, ADMIRAL LORD, was born at St. Peter Port, in the island of Guernsey, on the 11th of March, 1757. His family name, De Saussame, bears evidence of Norman extraction, and mention of it is found in the earliest records of the Channel Islands. From early youth he manifested a strong inclination for the naval service, in which several members of his family had distinguished themselves. When thirteen years of age he entered as a midshipman on board the Molt, that the English fleet fought the battle of Winchelsea and Levant frigates, under the respective commands of Admirals Goodall and Thompson. On his return to England in 1775, he joined the Briolet, of 50 guns, under the command of Captain Abarbil, under which he distinguished himself in the attack on Charleston, in America: the courage he displayed on that occasion was rewarded by promotion to the rank of lieutenant. From that period to 1779 he was actively employed in the coasting service, and was employed in the service for the expedition under Lord Cornwallis. He was afterwards appointed second-lieutenant to the Fortune, Ad-
Sir Hyde Parker, and he was in the engagement which took place with the Dutch fleet under Admiral Zoutman, off the Dogger Bank, on the 5th of August, 1781. His behaviour in this action, in which he was wounded, caused him to be promoted to the rank of commander, and appointed to the command of a squadron.

In the month of December following, Captain Saumares was ordered to place himself under the command of Admiral Kempenfelt who, with twelve sail of the line, was commissioned to capture the Spanish man-of-war by the Spanish fleet under the command of the Comte de Guichen, and which was destined to assist the Comte de Grasse in the capture of Jamaica. To inform Sir Samuel Hood, the English Admiral in the West Indies, of the intention of the French fleet to make this expedition, and the importance, and Captain Saumares was selected for this service. While at Jamaica he was enabled, through an exchange, to obtain post rank and the command of the Russel, a ship of the line. In this ship he greatly distinguished himself at the memorable battle of the 12th April, 1782. [Hood, P. C.; Rodger, P. C.]

On the 29th July following, he returned to the Russell to England, and from thence to his native island, where he enjoyed in the society of his friends the peace which was soon after proclaimed. On the breaking out of the war of the French revolution (January 1793), Captain Saumares was appointed to the command of the Crescent, which had been sent to Cherbourg, after a warm action of nearly two hours and a half, the French frigate 'La Réunion,' of 36 guns, but of larger size and with a much more numerous crew. The British had 20 killed and 50 wounded, the French had only one man wounded, and that by the recoil of a gun. The success of this action procured for him the brevet of knighthood, and was so generally admired by the merchants of London with a valuable piece of plate. In the month of November following, Sir James Saumares was placed under the orders of Admiral Machrie, who gave him the command of a squadron consisting of the Crescent and Druid frigates, a brig, and a cutter, destined to assist the attempts made by the French Royalists to join the rising of the Vendéans. On the 6th of June, 1794, an opportunity was presented to him of displaying his skill and ingenuity, when, by the capture of Plymouth to Guernsey with the Crescent, Druid, and Eurydice frigates, he was attacked by a French squadron of more than double his force. A running fight ensued, the brunt of which was borne by the Crescent and the Druid, to cover the escape of the Eurydice, which, on account of its inferior sailing, ran considerable risk of being captured. This object being effected, he closed in with the enemy in the Crescent, and thus enabled the Druid also to escape into the roads of Guernsey. He effected the escape of the Crescent by his cool intrepidity and a perfect knowledge of the difficult coast in which he was engaged. As soon as the other ships were secured, the Crescent was ordered to return, and, after avoiding being taken, ordering the pilot, a native of Guernsey, to steer through a narrow passage between the rocks, which had never before been attempted by a ship of her size; he thus rescued the ship and crew, which was enabled to defy every effort of the enemy to take their vessel.

In March, 1795, Sir James was appointed to the Orion, 74, and placed under the orders of Lord Bridport, in which ship he opened the memorable battle which took place on the 23rd of June. In 1797 the Orion was attached to the squadron sent to reinforce the fleet of Sir John Jervis off Cape St. Vincent, and took a prominent part in the glorious engagement with the Spanish squadron. [Jervis, John, P. C.] He was after this battle employed till the end of April, 1798, in the blockade of Cadiz, and then selected by Lord St. Vincent to join the squadron under Sir Horatio Nelson destined to the Mediterranean; he was ordered to Toulon. At the important victory of the Nile, Sir James, as senior captain, was the second in command, and his ship was the third which entered into action; the courage which he displayed in the action has been fully confirmed by the concurrent testimony of several who were present at the action. The admiral was rewarded by receiving the Order of the Bath. On the meeting of parliament, a motion made by the Earl St. Vincent for the removal of Sir James Saumares was carried, in which Sir James received the thanks of the House for his gallant conduct in his late actions with the combined fleets of France and Spain. Lord Nelson remarked that 'a greater action was never fought.' The thanks and freedom of the City of London were also voted to him, with a valuable sword.

At the peace of Amiens, Sir James Saumares returned to England, and, in 1803, a pension of 1200l. a year was conferred upon him. On the re-establishment of the Royal Navy, he was appointed to the command of the Channel fleet, under Sir Alan Gardner, to bring home from Lisbon the ships captured at the battle of the Nile.

During the winter of 1799 and 1800 he was entrusted with the command of the squadron which was commissioned to watch the French fleet in Brest. The difficulties to be encountered in this arduous service, particularly during the winter season, were very great; and it is no small praise to the careful vigilance of this commander to say that, during the whole time he remained on that station, not a single vessel sailed from or entered the port of Brest.

At the commencement of the year 1801, he was promoted to the rank of rear-admiral, and on the 17th of June following was appointed to the command of a squadron to watch the movements of the Spanish fleet at Cadiz. On this occasion he was created a baronet. On his arrival at Cadiz, information was given him that the Spanish fleet was confined in the bay of Algeciras, and immediately determined upon attacking them. The position of the French was one of great strength, defended by the batteries in the bay and fourteen large gunboats. The action commenced on the morning of the 6th of July, in which he had the misfortune to lose the Hannibal, 74, which accidentally grounded, and, after a long and sanguinary engagement, Sir James found himself compelled to repair to Gibraltar. The failure of his first attempt on the French fleet did not discourage him. Expecting that the enemy's squadron at Cadiz would make use of the first opportunity which the weather might offer of effecting an sortie, he cast off from Algeciras, he hastened to put his vessels in a state of repair. This object was effected in a remarkably short space of time. On the 10th of July, a French and Spanish fleet, consisting, with the rest of the ships of the line that had been captured, was seen steering for Algeciras, with a squadron of not more than half the strength of the enemy; the admiral determined to attack them between the black and white, of preventing their return to Cadiz, and, on the 12th, sailed out to attack them. The enemy formed their line-of-battle off Cabrera. Shortly after the commencement of the engagement two of the enemy's ships were discovered to be on fire, and about midnight blew up with a tremendous explosion. An accident which occurred at daylight to the Venerable, Captain Brenton, the disabled state of the English ships, and the sudden falling of the wind, prevented the admiral from attaining his object, which was to prevent the French and Spaniards re-entering Cadiz; they did so, however, with the loss of three sail of the line, and upwards of 3000 men, blown up, killed in action, and taken prisoners. An important result of this victory was the preservation of a large fleet of British merchantmen, which it was the object of the French to seize. A most unforeshadowed imputation has been attempted to be cast on the military character of Sir James Saumares by a well-known modern French historian, who has asserted that, contrary to the rules of war, red-hot shot was used by him in that engagement, and that it was owing to these means that the burning of the Spanish ships occurred. The men had no other means of avoiding being taken, ordering the pilot, a native of Guernsey, to steer through a narrow passage between the rocks, which had never before been attempted by a ship of her size; he thus rescued the ship and crew, which was enabled to defy every effort of the enemy to take their vessel. The admiral was rewarded by receiving the Order of the Bath. On the meeting of parliament, a motion made by the Earl St. Vincent for the removal of Sir James Saumares was carried, in which Sir James received the thanks of the House for his gallant conduct in his late actions with the combined fleets of France and Spain. Lord Nelson remarked that 'a greater action was never fought.' The thanks and freedom of the City of London were also voted to him, with a valuable sword.

At the peace of Amiens, Sir James Saumares returned to England, and, in 1803, a pension of 1200l. a year was conferred upon him. On the re-establishment of the Royal Navy, he was appointed to the command of the Channel fleet, under Sir Alan Gardner, to bring home from Lisbon the ships captured at the battle of the Nile.
The changes which took place in the aspect of affairs on the Continent having removed the presence of a British fleet in the Baltic no longer necessary, Sir James was recalled, and his recall accompanied by a letter from the Lords Commissioners of the Admiralty, in which they expressed ‘the usual sense of the zeal, judgment, and ability evinced by him during his late command.’

At the peace of 1814 he was raised to the rank of full admiral; on the visit of the allied sovereigns to England he received their personal thanks for the services which he had rendered to their cause, and, having accompanied them to Oxford, he obtained the honorary degree of Doctor of Civil Law. In 1819 he was appointed rear-admiral, and in 1821 vice-admiral of the Blue. In 1834 he was preferred to the command of port-admiral of Plymouth, which he held till 1827, and with it may be said to have closed his professional career. At the coronation of William IV. in 1831, he was raised to the peerage of the United Kingdom, with the title of Baron de Saumarez, of Saumarez, in the island of Guernsey—a reward which his long and important services had merited, and which it was expected he would have received at an earlier period. He was shortly afterwards made general of marines, and in 1834 an elder brother of the Trinity House. In the same year he was presented by the King of Sweden with a full-length portrait of himself, accompanied by the following letter, which showed that time had not effaced from the mind of the king the services rendered by Lord de Saumarez to Sweden. The remainder of his life was for the most part spent in the enjoyment of quiet and repose on his country estate in Guernsey. His religious zeal, charity, and affable demeanour had endeared him to his countrymen; and his death, which occurred on the 9th of October, 1836, was lamented as a public loss. He was succeeded in his title by his eldest son, James, the present peer, who is in holy orders.

SAVINGS' BANKS. The 5 and 6 Wm. IV. c. 57, passed in September, 1835, extended the provisions of the 2 Geo. c. 20, and of 5 & 6 Wm. IV. c. 14, to savings' banks in Scotland, and enabled existing banks to conform to the said acts by preparing and depositing their rules pursuant to these acts.

Military or Regimental Savings Banks were established by warrant dated October 11, 1843. The following is the amount of all sums deposited in them within the year ended March 31, 1844; of all sums withdrawn during the same period; and of the interest allowed upon such deposits; and also of the number of depositors on the 31st of March, 1844:

On the 9th of August, 1844, the royal assent was given to an act (7 & 8 Vict. c. 83) entitled 'An Act to amend the Laws relating to Savings' Banks, and to the Purchase of Government Annuities through the Medium of Savings' Banks.'

The first clause of this act reduces, from and after the 20th of November, 1844, the interest of all moneys invested by the trustees of savings' banks in the national funds, to the rate of 3½ per cent.; and s. 2 declares that the maximum of interest to be allowed to depositors shall not exceed the rate of 3½ or 3½ per cent.

From the same date every depositor, on making his first deposit (s. 3), shall sign a declaration as provided by previous acts, a copy of which is to be annexed to the deposit-book; and once in every year at least this book (s. 6) is to be produced at the institution for the purpose of examination.

Any actuary, cashier, or other person holding a situation at a savings' bank (s. 4), receiving deposits and not paying over the dividend to the managers, is liable to be punished as a misdemeanor; but no trustee or manager to be liable (s. 6) for any deficiency unless they have declared in writing their willingness to be so responsible, and this responsibility may be limited by the circumstances in cases of money actually and personally received by them.

When deposits are made in trust for another (s. 7), the sum is to be invested in the names of the trustees and the person on whose behalf it was so invested is not to be made not to have the receipt of both, or of their trustees, executors, or agents appointed by power of attorney.

Annuities under the 8 and 4 Wm. IV. c. 14, are not to exceed (s. 10), if a will or letters of administration are not produced within a month, the money may be paid to the widow, or the person entitled to the effects of the deceased; if a depositor be illiterate and die intestate, the managers (s. 11), with the sanction of the barrister appointed to certify the rules, may pay the same to such persons as would be entitled to the same under the statute of distribution, if all the parties were legitimate; and where married women have made deposits it is lawful for them to receive, without the husband’s consent, the interest, to the extent not exceeding 3½ or 4½.

Where deposits exclusive of interest do not exceed 50l. (s. 10), if a will or letters of administration are not produced within a month, the money may be paid to the widow, or the person entitled to the effects of the deceased; if a depositor be illiterate and die intestate, the managers (s. 11), with the sanction of the barrister appointed to certify the rules, may pay the same to such persons as would be entitled to the same under the statute of distribution, if all the parties were legitimate; and where married women have made deposits it is lawful for them to receive, without the husband’s consent, the interest, to the extent not exceeding 3½ or 4½.

The time for issuing the half-yearly receipts for interest is extended (s. 13) to sixty days from and after the 20th of May and 20th of November, and the time for transmitting the annual statement is extended to nine weeks after the 20th of November in each year.

Any dispute between the depositors and the managers is to be settled (s. 14), by a barrister appointed under the previous acts, whose award is to be exempt from stamp-duty; the barrister is empowered for this purpose...
to inspect the books of the institution, and to examine witness on oath or affirmation: false evidence to be punished as a

Bond as given as security under previous acts (9 Geo. IV. c. 92, and 3 & 4 Wm. IV. c. 14) are to be deposited with the Commissioners for the Reduction of the National Debt (s. 10), to which the Governor, or any other officer or trustee, is bound to hold tender of not less than half the amount of the bond. Every officer of which the further receipt or custody of money (s. 17) is to give sufficient security, such security when given by bonds, is to be deposited with the principal and three managers when required to be cancelled. The direction for depositing the rules of a savings' bank with the clerk of the peace (s. 18) is repealed; bonds, written or otherwise, are not to be taken from the barrier for his certificate, who, on approval, is to return one copy to the institution, and transmit the other to the commissioners.

Payments to the relations of intestate depositors (s. 21) are to be made to the next of kin by the law of Scotland, in the case of deposits in that country.

The set is declared (s. 22) to extend to societies for purchasing annuities as well as to savings' banks, and (s. 23) to Great Britain and Ireland, Berwick-upon-Tweed, Guernsey, Jersey, and Isle of Man.

The name (s. 41) is C. S. A. (Cesarei, the Latin word for scab or itch, which disorder the common sort is said to cure), a genus of parasitic belonging to the natural order Dipaecidae. The inner calyx consists of 5 bristles, the outer one is membranous and plaited. The receptacle is exserted, with 8 clefts and 8 excavations. The corolla of 5-cleft with 4 stamens. The species are perennial or suffrutescent herbs with variable leaves. S. scutellaria, Devil's-bit, has an abrupt root appearing as if it were bitten off at the end, the heads of the flower and fruit nearly globose, the outer calyx hairy, 4-cleft, the lobes ovate acute, the inner calyx consisting of 5 bristles. The corolla is 4-cleft, the lower leaves toothed, the upper ones entire. The stem and both sides of the leaves hairy or glabrous. The flowers are dark violet or purple, varying to flesh-colour and white. It is native of Europe to the Caucasus, and is very plentiful in Britain. In cultivation the plant becomes much more branched than in a wild state. In days of superstitition it was said to be the devil's eating meat, hence its common name. According to Bergen, the root is astrigent, and an infusion of it is bitter and not unpleasant. A strong decoction of it was formerly an empirical secret for gonorrhoea. Linnaeus says the dried leaves are used to dye wool yellow or green. It is usually regarded as the type of the C. S. A. of Britain, but Fras thinks the plant of Discodiscos is the S. A. S. Brownioides.

S. colubrina has the outer calyx membranous, plaited, and notched, the inner one of 5 nerveless bristles; the corolla 4-cleft, the stamens 4. It has been discovered that, under the rays of light, the inner calyx, the involucres, the upper leaves pinnatifid, with linear segments. The flowers are purplish, the involucres narrow. It is native of Europe, Caucasus, and Siberia, and is very common on chalk and chalky grounds. The corolla is much rounder than the leaves, and the tips are acute. It is nourished with reddish tubes. The calyx consists of 5 reddish brown bristles. It is native of Barbary, Italy, and Sicily in fields, and is a cultivated plant.

Many of the species of this genus are well adapted for garden borders. The perennial and herbaceous kinds are easily increased by seed or by dividing at the root. The seeds of the annual kinds only require to be sown in the open ground; the shrubby species are increased by cuttings under a bank of peat, or by seed. (Don, Gardener's Dictionary; Lindley, Vegetable Kingdom; Botanical Magazine, of British Botany.)

Sca/vo/la, Qu. Cer/evi/duis, a Roman jurist, probably gave response in the time of Antoninus Pius (Dig. 34, tit. 1, s. 18); but he was certainly employed by Marcus Antoninus as a legal adviser (J. Capitularies, Marcu, 11; Dig. 34, tit. 1, s. 18). In his writings he speaks of the constitutions of Marcus and Verus, in terms which imply that they were alive. Septimius Severus, afterwards emperor, and Tafinian, Nellus, Capit. Ceres, who probably died in the year 203 (S. Severilis, Septimii, Capit. Ceres, 8). His response were often very brief, expressed in a single word (Dig. 17, tit. 1, s. 63); but the facts of which the opinion is given are clearly stated. His style has been blamed as obscure; but there is evidence of his great capacity, and he left a name behind him.

There are excerpts in the Digest of Justinian from his forty books of Digesta, six books of Response, twenty Libri Disputitationum publice tracurarum, probably a book of decided cases. The Florentine Index also mentions a single book 'De Quaestione Familiaris,' but there is no excerpt from it in the Digest. There are 307 excerpts from the writings of Scaevola in the Digest.

Many of the Responses of Scaevola appear twice, both in the Responsum and De Quaestione. As far as the author can see, the Digesta contained a fuller statement of the matters which are briefly indicated in the Responses, and were a kind of commentary to the Digesta. Puchta says that the passages in the Digesta do not show this; and that this relation is rather that of the Quaestiones to the Responses: 'the Quaestiones were devoted to the complete examination and justification of the opinions.'

Claudius Tryphonus and Paulus commented on Scaevola, and he is often cited by Marcianus, Tryphonus, Ulpius, Paulus, and Modestinus. Scaevola commented on Julian and Ulpius Marcellus.

A small leaflet, a remarkable cephalophagous fossil genus, irregularly convoluted at both ends, and occurring in the lower parts of the cretaceous system. (Parkinson.)

Sca/phi/ดus, a genus of fossil fishes from the oilite of ornithoid. (Asa.)

Scarlet Fever. [Scarlatina, P. C.]

Scarlett, Right Hon. Sir James, Lord Abinger, was a native of Jamaica, where his family was very wealthy and of long standing. He was the second son of Robert Scarlett, Esq., and was born in or about the year 1769. His mother's name was Elizabeth Anglin. The family estates went, it may be presumed, to the eldest son; a third son, who also remained at home and followed the profession of the law there, became Sir William Anglin Scarlett and Chief Justice of Jamaica, and died not long ago after having held that office for many years; James was at an early age sent to England. Having finished his elementary education, he was, about the year 1786, entered a Fellow Commoner at Trinity College, Cambridge; and he was also, a year or two after, admitted a student of the Inner Temple. He took his degree of A. B. A. in 1794, 1795, and 1796; and graduated M. A. in 1794. His success at the bar was very decided from the first, and every year added to his reputation and his emoluments. It was soon considered that the name of Scarlett should be changed so as to gain a large proportion of r evards. Even while he was still a junior counsel, he was very frequently entrusted with the sole conduct of important cases. At last, in 1816, he received a silk gown, and it was clear from that date he was recognised as the leader of his circuit (the Northern), and as occupying also a foremost place in Westminster Hall.

He had made an attempt to be returned to parliament for the borough of Lewes at the general election in October, 1812, but was defeated by Mr. George Shiffler, who was brought in, as second member, by a majority of 164 to 166; and he failed also in a second attempt on the same borough when a vacancy was occasioned in 1816 by the death of the other member, Mr. T. R. Kemp, being then defeated by Sir John Shelley. He was first introduced to the House of Commons in 1816, as one of the members for the city of Peterborough, under the patronage of Earl Fitzwilliam. He did not, however, make a figure in parliament corresponding to his eminence at the bar; nor was he a frequent speaker, although he both supported Sir Samuel Romilly and Sir James Mackintosh in their efforts to mitigate the severity of the criminal law, and also occasionally took part in debates on financial subjects.

He was returned again for Peterborough at the general election in 1826, but he resigned his seat in 1827 to stand for the University of Cambridge, and was returned by the University at the bottom of the poll. Upon this he was re-elected for Peterborough, but not till after a contest with Mr. Samuel Wells. Up to that time he had been considered as distinctly belonging to the Whig party, but he then broke all connection with that section of it; but his opinions gradually assumed more of a
Conservative complexion, and when the new Tory or mixed administration of Canning came into power in April, 1827, Mr. Scarlett, having been again returned for Peterborough at the general election of that year, accepted the office of attorney-general. He was at the same time knighted. Having been once more returned for Peterborough he retained his place till the administration of Lord Goderich; he succeeded by Sir Charles Wetherell when the Duke of Wellington became premier in January, 1828; but was reinstated in May, 1829, upon the dismissal of Sir Charles for his opposition to the Catholic Emancipation Act on the Bill; and, having been returned for Maldon at the general election in 1830, he remained attorney-general till the accession to office of the Whigs in November of that year, when he was succeeded by Mr. Brougham.

At the general election in May, 1831, Sir James Scarlett was returned to parliament for Cockeremouth. At the next, which took place after the passing of the Reform Bill, in December, 1832, he was returned, after a contest, for Norwich, along with Lord Stormont (now Earl of Mansfield). When this parliament was dissolved in December, 1834, on Sir Robert Peel being appointed premier, Sir James Scarlett was made Chief Baron, and a peer by the title of Baron Abinger, of Abinger, in the county of Surrey, and of the city of Norwich.

Lord Abinger died of a sudden attack of illness at Busty Street, on the circuit, on the 7th of April, 1844. He had been married twice; first in August, 1792, to the third daughter of Peter Campbell, Esq., of Kilmory, in Argyllshire, who died in March, 1829; secondly, in September, 1829, to the daughter of Lord and Lady Stranraer, of Jays, Surrey, and widow of the Rev. H. J. Ridley, of Ockley. By his first wife he had three sons and two daughters, by the eldest of the former of whom he is succeeded in his title and estate. His eldest daughter married Mr. (now Lord) Cornwall in 1821, and was created a peeress in 1836 by the title of Baronesse Stantheden.

Lord Abinger was a skilful and dexterous rather than an enterprising politician, and while on the bench he was more distinguished for the clearness with which he summed up a case to a jury than for the profundity or subtlety of his legal views. Yet he was considered also a sound and good lawyer. In the great art of gaining verdicts he was unrivalled; and no practicioner at the bar had ever before received so large a sum in fees in any year as he drew in the height of his practice. His conduct as attorney-general under the Tories in 1829, when he filed a number of criminal informations against the opposition newspapers, naturally exposed him to some severe animadversions from those who still continued attached to the more democratic political creed which he had originally been accustomed to profess.

Gent. Mag. for June, 1844.)

SCHEUFELEN or SCHEUFFELEIN, HANS LEONARD, commonly called Hans Scheuffelin, a very celebrated old German painter and wood engraver, was born in Nürnberg about 1490. His father Franz Scheuffelin was a merchant, and his mother, Ursula, daughter of Hans was placed with Albert Dürer, with whom he was a great favourite. He remained in Nürnberg until 1515, when he removed to Nördlingen, where he died in 1580 or 1560; probably the same year in which his widow was married again in 1540 to the painter Hans Schwarz.

There are several of Scheuffelin's paintings in Nördlingen, which the principal is the Taking down from the Cross in the church of St. George; it is a picture with two revolving wings, and was painted in 1521. There are several good paintings by Scheuffelin also in Nürnberg, Tübingen, Stuttgart, Oberdor, and other neighbouring places; and there are some in the galleries of Munich and Berlin.

There are also many woodcuts by Scheuffelin, and both woodcuts and pictures are sometimes attributed to Albert Dürer, to whom however Scheuffelin was inferior in all respects.

Bartsch, Peintre Graveur; Nagler, Neues Allgemeines Künstler Lexicon.

SCHEURTEL, LEVIN KARL FRIEDRICH, in the opinion of his own countrymen the great architectural artist of his age, and whose name has obtained European and permanent celebrity, was born March 13, 1781, at Neu-Ruppin, in Brandenburg, on the Elbe, the son of a painter sculptor, who had six years old he lost his father, and was placed by his mother in the 'Gymnasium' of his native town, where he remained till the age of fourteen, when he removed to Berlin. Soon afterwards an opportunity presented itself of becoming a pupil of the elder Gilly (David Gilly, born 1745, died 1808), a clever practical man in his profession, and author of several works on subjects relating to it. Hardy could he have been more fortunately placed; for about a twelvemonth afterwards, the younger Gilly (Friedrich) returned from his travels with an imagination warmed by his recent studies, and from him it was that Schinkel derived his best instruction, and together with an ardent relish for his art, more liberal and enlightened idea of its powers as a fine art were generally entertained in those days, when a system of mere routine both in theory and practice prevailed almost universally. Friedrich Gilly, the elder, was ambitious of elevating the architecture to the level of the other arts of design, and to bring it into immediate contact with them, whereas it was then, and perhaps now, is, too much regarded as one entirely apart from and independent of the arts of design, which himself would have achieved in his profession can only be conjectured, for he died within two years after his return, August, 1800, before he had completed his thirteenth year, leaving Schinkel to infer what he was unable to form or achieve. His studies had acquired such proficiency in practice it would not have been
difficult for him to have adhered to that course under others in the profession, and in the course of time establish himself in business; but he preferred pursuing his theoretical and artistic studies, containing in them to account by making designs of various ornamental articles for modellers, metal-workers, and other artisans of that class. Out of such earnings he laid by sufficient to enable him to study and to make copies of the great art termed the 'holy land of art.' In 1803 he set out for Italy, first visiting Dresden, Prague, and Vienna; and after extending his route to Naples and Sicily, returned to Berlin in the spring of 1805. But there the state of things was such that junction anything beyond the most exquisite to art, more especially architecture, to which the state of public affairs in 1806 and following years threatened a complete stoppage. He turned to landscape-painting, therefore, as an occupation, and set out to imitate the various scenes of scenery which he brought home from Italy, and embellishing his compositions with architectural accessories, or else making the architecture principal and the landscape the accessory portion of the subject. One work of note and which gained him distinction with the public was a large panorama of Palermo; and he also designed for the theatre many sets of scenes, a collection of which, including those for the Mozartfete, Die Braut von Messina, &c., were afterwards published in a series of colored engravings, whereby they are rescued from the usual fate of similar productions of the pencil. His various artistic labours during this period were, however, insufficient to make a fortune for his family, or to call forth and exercise those two faculties in which those who are otherwise able architects are generally deficient—taste and imagination. Even had they been serviceable to his path, they would have been insufficient to give the public a real conception of Schinkel's designs for the decoration of the new theatre, which was intended to confer a new aspect on Berlin, and conferred on it a high architectural character. One of the earliest commissions of importance which he received from the king (who was then at London with the allies), was to make designs for national cathedrals intended to commemorate the pacification of Europe; but though the architect's ideas excited great admiration, the scheme itself was dropped. Whatever the disappointment may have been at first, he had no time to dwell upon it, for from the period of 1815 he was incessantly and most actively engaged. Among his earliest buildings were the Hauptwache, Theatre, and Museum at Berlin, all of them treated in a pure Hellenic style—a style which had only been hinted at in such previous attempts at correct Grecian architecture as Langhans's once celebrated Brandenburg Gate. The façade of the Museum more especially displays, together with severe simplicity and correctness of detail, a freedom from superfluity and unthought-of for any previous modern example which is called Greek. The external elevation consists of merely a single line of eighteen columns in antis (Erechtheum Ionic) raised on a first and second floor. The first is a flight of steps, enclosed by pedestal walls (in continuation of the stylobate) and forming the ascent to the colonnade. Taken by itself, however, there would be nothing very remarkable in the general idea, whereas an extraordinary degree and kind also of variety and effect are given to the whole by the inner elevation or background behind the outer row of columns; which presents in the centre portion of it a second colonnade (four columns in antis), with a screen-wall rising about half its height, and above and beyond that the upper part of the open staircase, whereby the whole composition acquires singular movement and play both of perspective and light. How much the making the rest of this interior elevation, instead of being left a blank surface, or nearly so, is completely decorated from top to bottom, or rather was intended to be so, the upper division of it on each side of that inner colonnade being to be filled up by a single large fresco, the cartoons or designs for which were prepared by Schinkel himself, and have been extolled as masterly compositions. There is reason, however, to suppose that either they have not been completed, or the work is imperfect. It is being spoken of as the artist to whom the task is to be confided; and only when the frescos shall have been added, will Schinkel be able to see the effect contemplated by him for the building he has been engaged. Neither is the Museum the only one of his works which have not been completed—not yet, at least, according to his designs; for the two other buildings above mentioned have not received their full complement of sculpture, which, though it may be dispensed with for them as structures, is essential to them as works of architecture. It is fortunate, therefore, that in any case we have Schinkel's own ideas while they are still fresh in his mind. Whether he can be induced to put them into execution, or whether the various and extensive series of designs of all his principal buildings, some of which are illustrated and explained far less sparingly than is the custom in similar collections; for besides ornamental details, on which the designs are crowded, rare and tasteful, perspective views interior as well as exterior, and different ones of the same building are given; besides which, the engravings themselves are illustrated by the information contained in the letter-press, the publication of his designs contributed no doubt to spread Schinkel's fame much more rapidly than would otherwise have been the case; and it is that one forms a very complete gallery of his unusually numerous and never stilted visions of instruction. With such ready materials, a descriptive catalogue of his buildings might be easily drawn up, but we can merely mention a few of them: the Werder Kirche (Gothic), Bauschule, and Observatorium, at Berlin; the Theatre at Hamburg; Schloss Kronsnowitz, Charlottenhof, and the Nicolai Kirche at Potsdam, which last would have been a most imposing structure had the design been carried out, instead of being cut down altogether by the omission of the cupola. His 'Entwürfe' also contains his design for the Sing-Academie at Berlin—one of his happiest ideas, which was unfortunately set aside for that by Ottmer (Ottmer, P. C. S.); and six designs for a monument to the memory of Goethe and his free scope to his imagination, and indulged in luxuriant architectural pomp. Another publication, entitled 'Werke der Hohen Baukunst,' gives us a series of designs by him for the Albertinum at Dresden, for the royal palace at Aix-la-Chapelle, for the palace at Apocapoli, forming an irregular assemblage of courts, colonnades, and buildings, some of which, especially one magnificent saloon, would have been marked by originality of character as well as by the most effectual, for its design was much superior to that by Klenze, which is also published among those of the latter architect's; but, as has been said already elsewhere [Atlanca, P. C. S.], neither of them was adopted. Another remarkable project of Schinkel's, his last, but not his least poetical conception, was a design for a summer palace at Orlands, in the Crimea, for the Empress of Russia, surrounded by terraces and hanging gardens on a lofty eminence, commanding a prospect of the Black Sea. That was in 1839, the same year in which was conferred upon him the highest rank in his profession—that of Ober-Landes-Baudirektor; but it was to him a mere honour, for his career was closed; his health immediately after his election, and in the autumn of the following year, on his return from the baths, by whose waters he had hoped to benefit, he was attacked by an organic affection of the brain, which reduced him to a state of almost perpetual insensibility, to paralytic fits; and in that deplorable condition he remained upwards of a twelvemonth, till released from it by death on October 9th, 1841.

Schinkel has been called by some of his countrymen the Luther of Architecture; and he certainly gave a fresh impulse to the art: and if he himself did much, his example and influence have probably accomplished more; for by venturing to think for himself, he has led others to do the same. Yet with all his freedom and originality, he was, perhaps, rather too timid than too bold in his reforms, adhering in many respects too strictly to the original letter of Grecian examples, particularly in regard to the orders. As to Gothic, it would have been better had he abstained from it entirely, and given his undivided attention to the other style, first elevating and then maturing new ideas from it. With all his invention, too, he had expected none upon which such important features as doors and windows, for which he repeats the very same design again and again in different buildings.

Schinkel has been made the subject of biographical notices and of criticism more than any other modern architect. Of two separate publications relative to him, one entitled 'K. F. Schinkel, Eine Characteristik,' &c., 1842, is by Dr. Kugler; the other by O. F. Gruppe; and both of them have the portraits of him, but in the latter work the names of those who represent him in his usual dress, and with his hat on, and therefore conveys a better idea of his personal appearance.

SCHIZODUS, a fossil genus of conchifera, proposed to include species of Aequus of Sowerby.

SCHIZOPITTERIS, a genus of fossil ferns (Brenniaria) in the shales of the Yorkshire coast.

P. C. S. No. 151.

Vol. II. 3 X
CHIZIOSTOMA, a fossil genus of fossil gastropoda (Brom). Included in Euomphalus, or Pleurotomaria by other writers. Found in the paleozoic strata.

97. AUGUST WILHELM VON SCHLEGEL, was descended from a family in which learning and literary fame had been hereditary during several generations, in Germany as well as in Denmark, where a branch of the family settled early in the 18th century. His father, Johann Adolph Schlegel, D.D., who died in 1738, as Superintendent General of the Lutheran Church of Hanover. John Adolphus had four sons, Charles Augustus Maurice, superintendent-general at Hildesheim; John Christoph, who died in 1780; and John Christian, to whom Schlegel's name is popular to a degree which he would perhaps not have enjoyed at another time. 'Das Deutsche Museum,' a review which the brothers Schlegel founded in 1812, was the chief organ of the German Romantic movement. His brother, Christian, was a well-known literary critic and editor. Schlegel was trained in a liberal arts college and later studied law, but he was more interested in literature and philosophy.

Augustus William was born at Hanover on the 8th of September, 1767, and after having received a careful education was sent to Göttingen to study divinity, which he soon abandoned to devote his time to philosophy. Though young, he was no common classical scholar, for his Latin dissertation on the geography of Homer was highly thought of by Voss, then the professor of history. Among his earliest religious works was a Heine intrusted him with making an index to his edition of Virgil. For some years Schlegel lectured at the university of Jena on the 'Akademische Vorlesungen über Schöne Kunst' (especially his poem 'Ariadne,' and his essay on Dante), and to Schiller's 'Musen-Almanach' and 'Horen,' especially his translations from Dante with commentaries, secured him an honourable rank among the best writers of Germany. In 1797 he published the first volume of his translation of Shakespeare. In the same year he was appointed professor of Humaniora in the university of Jena, and continuing his literary activity he soon placed himself among the leaders of German literature. He remained at Jena till 1802, a friend of Schiller, and an admirer of Goethe, who then at Weimar, who, however, did not return the sentiment. Pushed by ambition, Schlegel left the little town of Jena, and repaired to Berlin, where he gave public lectures to a mixed but highly intelligent public on literature and the fine arts. He remained there till 1808, having meanwhile imbued that扑克 passion for little court distinctions, titles, and crosses, which in later years proved such a severe drawback on his real merits.

Among the specimens of his literary activity in the period from 1797 to 1805, may be mentioned, besides the continuations of Shakespeare's play 'The Alchemist,' a review, which he edited with his brother Frederic, and which did a great deal of good towards purifying the taste of the public; 'Gedichte' (Poems), Tübingen, 1800; 'Triennium,' which he edited with the 'Revue de Paris' and in which he first betrayed his growing tendency towards Romanism and mysticism; 'Vorlesungen über Literatur und Kunst des Zeitalters, (Lectures on the Literature and the Fine Arts of the Times), which appeared in 1803, 1804, and 1805, and was reviewed by Frederic Schlegel. In 1806 he made the acquaintance of Madame de Stael-Holstein. Surprised at finding so rare a combination of deep learning, uncommon poetical talents, and the manners of a courtier as Schlegel presented, she became his sincere friend, and he henceforth accompanied her during several years on her travels through various parts of Europe. The reciprocal influence of these two distinguished persons on each other was very great, and may be traced in their works: the result was, that he made her popular in Germany, and she brought him out in France, where his vanity afterwards met with so much gratification. At her invitation he published in France a correspondence between the Phébus de Racine and the Hippolytus of Euripides, and this work was the foundation of his subsequent fame among the French. In 1808 Schlegel delivered at Vienna a course of lectures on Shakespeare, and gave an evergreen monument to his genius. They were published under the title 'Vorlesungen über Dramatische Kunst und Literatur,' Heidelberg, 1809, 8vo. 2nd edition of 1813. The collection of his poems appeared in 1811, 2nd edition, 1820, among which are his masterpieces, Arion, Pygmalion, Saint Lucas, and others. At that time Schlegel and his brother Frederic were most successful in founding, in opposition to the models commonly called classical, the modern romantic school of poetry and fine arts which had its origin, in a great measure, in the depressed state of Germany and the deep wishes of the people for a moral, religious, and political reformation. Generations of enthusiastic patriots, and Augustus William having ventured to depreciate the French drama and to call Molière a mountebank, at a time when such liberties met with punishment or imprisonment, Schlegel was held in contempt and was regarded as a popular to a degree which he would perhaps not have enjoyed at another time. 'Das Deutsche Museum,' a review which the brothers Schlegel founded in 1812, was the chief organ of the German Romantic movement. His brother, Christian, was a well-known literary critic and editor.

The effect of 1815 produced a strange effect upon Augustus William: he accepted a secretariship from Bernadotte, the crown-prince of Sweden, and wrote political essays. No sooner however was Paris taken than he repaired to the country-seat whither Madame de Stael had retired, and kept her company till her death in 1818. She remembered him in her will. About that time he was placed among the titular nobility of Germany, the privilege of which enabled him to sign his name with a 'V' before his Christian and the family name of the person thus distinguished.

In 1819, Augustus William von Schlegel was appointed professor of history in the university of Bonn, which had just been founded by the king of Prussia: it is not known why he was made professor of history, for he had never written on history. He had now ceased to be a poet, but still ambitious of the honour of being a European author, he published several critical essays—of undoubted merit, however—in foreign languages. Such are, 'Le Couronnement de la Ste. Vierge, et les Miracles de la Trinité; Tableau de Jean de Fiesole; avec une notice sur la Vie du Peintre,' Paris, 1817, fol.; an essay on the famous Venetian horses, which he declared to be of Greek workmanship, in Italian, in the 'Biblioteca Italiana;' 'Réflexions sur l'Etude des Langues Asiatiques, adressées à Sir J. Macintosh, suivies d'une Lettre à Mr. H. H. Wilson,' Bonn, 1832, 8vo. To such minor works, however, he devoted only part of his time, for even previous to his appointment at Bonn, at the suggestion of his brother Frederic, he had made up his mind to study Sanscrit. He soon attracted a small number of students round him, and thus became one of the principal promoters of the study of the Sanscrit. The printing-office at Bonn owes its foundation to Schlegel, who, it is said, purchased the types at his own expense. Although he did not attain the exact knowledge of that difficult language which his junior brother with the aid of Bopp and others was yet no contemptible Sanscrit scholar, and surpassed Bopp and others in his general views: and it may be said that his principal merit consisted in encouraging students and aiding the study of the Indian languages, and other Indo-Persian languages. Schlegel in his turn was assisted by the superior learning of Professor Lassen. As early as 1820 he founded the 'Indische Bibliothek,' a review exclusively devoted to Indian languages and antiquities. Specimens of Schlegel's Sanscrit scholarship are, 'Ramâyana,' with a Latin translation and critical notes, Bonn, 1829; 'Bhagavat-Gita,' an episode of the celebrated Indian epic 'Maha-bharata.' It is especially interesting to the student of the study of the Indian languages, as well as to some of his critical essays on subjects connected with the fine arts and poetry that Schlegel owes the great esteem which he enjoyed in this country, and which is still maintained. In May, 1846, he published 'Essais littéraires et historiques,' Bonn, 1842, 8vo.
SCHMIEDELIA (in honour of Casimir Christopher Schmiedel, once a professor at Erlangen), a genus of plants belonging to the natural order Sapindaceae. It has a 4-lobed calyx. Petals obovate, 4-lobed, usually purplish. The petals from 6 to 10, inserted between the margin of the disk and the ovary. The ovary is ovoid, with 4 ovoid, ovulate, ovary cells each. The stigma 2-lobed. The style is an indubitable flower, which is receptive. The petals are similar in each cell, and covered with a pulpy aril. The embryo is much curved. The species are trees; the leaves abruptly pinnate, the leaflets nearly opposite. The flowers are small, discolored. L. trigyna has abruptly pinnate leaves from 6 to 16 inches long, the leaflets from 2 to 4, opposite, sessile, broad, lanceolate or oblanceolate, rather smooth on both sides the lower pair, the smallest from 3 to 8 inches long. The petals are a little downy, the stipules wanting. The racemes are axillary, or below the leaves round the base of the young shoots, solitary, in the male simple, in the hermaphrodite often compound, from 2 to 4 inches long. In the male flowers the calyx is cup-like, and 4-lobed. The corolla wanting, the filament from 6 to 10 erect, and many times longer than the calyx. The anthers oval and erect; the pistil a mere rudiment. The ovary is ovoid, ovulate, 3-lobed, with 3 ovoid ovules in each cell. The style is an indubitable flower, which is receptive. The petals are similar in each cell, and covered with a pulpy aril, which is of a pleasant acid taste, and most grateful during dry weather. It is a native of insular and continental India, where the astrangent bark, mixed with oil, is used as a remedy for the itch. (Lindley, Flora Medicina; Lindley, Vegetable Kingdom.)

SCHÖBERLIA, a genus of plants belonging to the natural order Chenopodiaceae. It has 5-stamen stamens from 6 to 10, inserted between the margin of the disc and the ovary. The ovary is ovoid, with 5 ovoid, ovulate, ovary cells each. The stigma is a 5-lobed disk. The style is an indubitable flower, which is receptive. The petals are similar in each cell, and covered with a pulpy aril. The embryo is much curved. The species are trees; the leaves abruptly pinnate, the leaflets nearly opposite. The flowers are small, discolored. L. trigyna has abruptly pinnate leaves from 6 to 16 inches long, the leaflets from 2 to 4, opposite, sessile, broad, lanceolate or oblanceolate, rather smooth on both sides the lower pair, the smallest from 3 to 8 inches long. The petals are a little downy, the stipules wanting. The racemes are axillary, or below the leaves round the base of the young shoots, solitary, in the male simple, in the hermaphrodite often compound, from 2 to 4 inches long. In the male flowers the calyx is cup-like, and 4-lobed. The corolla wanting, the filament from 6 to 10 erect, and many times longer than the calyx. The anthers oval and erect; the pistil a mere rudiment. The ovary is ovoid, ovulate, 3-lobed, with 3 ovoid ovules in each cell. The style is an indubitable flower, which is receptive. The petals are similar in each cell, and covered with a pulpy aril, which is of a pleasant acid taste, and most grateful during dry weather. It is a native of insular and continental India, where the astrangent bark, mixed with oil, is used as a remedy for the itch. (Lindley, Flora Medicina; Lindley, Vegetable Kingdom.)

SCHÖBERLIA, a genus of plants belonging to the natural order Chenopodiaceae. It has 5-stamen stamens from 6 to 10, inserted between the margin of the disc and the ovary. The ovary is ovoid, with 5 ovoid, ovulate, ovary cells each. The stigma is a 5-lobed disk. The style is an indubitable flower, which is receptive. The petals are similar in each cell, and covered with a pulpy aril. The embryo is much curved. The species are trees; the leaves abruptly pinnate, the leaflets nearly opposite. The flowers are small, discolored. L. trigyna has abruptly pinnate leaves from 6 to 16 inches long, the leaflets from 2 to 4, opposite, sessile, broad, lanceolate or oblanceolate, rather smooth on both sides the lower pair, the smallest from 3 to 8 inches long. The petals are a little downy, the stipules wanting. The racemes are axillary, or below the leaves round the base of the young shoots, solitary, in the male simple, in the hermaphrodite often compound, from 2 to 4 inches long. In the male flowers the calyx is cup-like, and 4-lobed. The corolla wanting, the filament from 6 to 10 erect, and many times longer than the calyx. The anthers oval and erect; the pistil a mere rudiment. The ovary is ovoid, ovulate, 3-lobed, with 3 ovoid ovules in each cell. The style is an indubitable flower, which is receptive. The petals are similar in each cell, and covered with a pulpy aril, which is of a pleasant acid taste, and most grateful during dry weather. It is a native of insular and continental India, where the astrangent bark, mixed with oil, is used as a remedy for the itch. (Lindley, Flora Medicina; Lindley, Vegetable Kingdom.)

SCHÖBERLIA, a genus of plants belonging to the natural order Chenopodiaceae. It has 5-stamen stamens from 6 to 10, inserted between the margin of the disc and the ovary. The ovary is ovoid, with 5 ovoid, ovulate, ovary cells each. The stigma is a 5-lobed disk. The style is an indubitable flower, which is receptive. The petals are similar in each cell, and covered with a pulpy aril. The embryo is much curved. The species are trees; the leaves abruptly pinnate, the leaflets nearly opposite. The flowers are small, discolored. L. trigyna has abruptly pinnate leaves from 6 to 16 inches long, the leaflets from 2 to 4, opposite, sessile, broad, lanceolate or oblanceolate, rather smooth on both sides the lower pair, the smallest from 3 to 8 inches long. The petals are a little downy, the stipules wanting. The racemes are axillary, or below the leaves round the base of the young shoots, solitary, in the male simple, in the hermaphrodite often compound, from 2 to 4 inches long. In the male flowers the calyx is cup-like, and 4-lobed. The corolla wanting, the filament from 6 to 10 erect, and many times longer than the calyx. The anthers oval and erect; the pistil a mere rudiment. The ovary is ovoid, ovulate, 3-lobed, with 3 ovoid ovules in each cell. The style is an indubitable flower, which is receptive. The petals are similar in each cell, and covered with a pulpy aril, which is of a pleasant acid taste, and most grateful during dry weather. It is a native of insular and continental India, where the astrangent bark, mixed with oil, is used as a remedy for the itch. (Lindley, Flora Medicina; Lindley, Vegetable Kingdom.)
SCH 524 SCH

S. myriocns is found on turfy bogs in Great Britain. It has a round naked stem, from 5 to 10 spikelets, collected into a terminal roundish head, overtopped by the lower bract; the glumes subacute at the keel. The stem is clothed at the base with dark-brown smooth shining scales, some of which continue in setaceous ciliate leaves, which are shorter than the stem. The glumes are dark-brown or black. This is the

SCHOOLS, INFANT. In the article Schools, P. C. p. 38, in speaking of the foundation of the Infant Schools at New Lanark, Mr. Wilson says: 'In 1819 Robert Owen went to London, having the idea of the Rev. William Turner, of Newcastle-on-Tyne, who, in the year 1818, when in conversation with Mr. Owen, remarked that in her attention to the education of girls, she had frequently wished some means could be adopted for getting poor children taken out of the hands of their parents at an earlier age, before they had formed bad habits at home, and among the idle children around them.' Much was said on both sides on the desirability of infant-schools, which Mr. Owen immediately established on his return to Lanark.

The author of the article Schools has informed the editor of the P. C. that his authority for this statement was a written communication from the Rev. William Turner before-mentioned. The statement however is proved to be erroneous by what is said by Mr. Owen in his report of the House of Commons in 1816. Henry Brougham, now Lord Brougham, was chairman of the committee, and the evidence is printed in the "Report from the Select Committee of the House of Commons on the Education of the Lower Orders in the Metropolis, June 1816."

Mr. Owen stated before the committee that he had paid particular attention to the education of children for twenty-five years, but that he had no opportunity of nuturing any of his pupils into execution till he went to New Lanark. He stated that he had been upwards of six years in the superintendence of the cotton-mills there, and that there were 444 children in his schools. He then was examined (1816) of from three to ten years of age, inclusive. As to the origin of the schools he says, 'I have been led in the establishment at Lanark, to receive children at the age of three years, principally for the purpose of preventing them from acquiring bad habits, which they would have done if they had been permitted to ramble in the streets among children who were ill instructed, and whose habits were bad; and also for the purpose of giving them good habits, and settling the knowledge they acquire more firmly in their minds. They are continued in the school upwards of seven years.'

Mr. Owen gave the following account of the management of the school:

'Harmon was received into a preparatory or training school at the age of three, in which they are perfectly superintended, to prevent them acquiring bad habits, to give them firm relations to form their character and habits, and a sincere desire to contribute all in their power to benefit each other. These effects are chiefly accomplished by example and practice, precept being found of little use, and not comprehended by them at this early age. The children are taught also whatever may be supposed useful that they can understand, and this instruction is combined with such amusement as is found to be requisite for their health, and to render them active, cheerful, and happy, fond of the school and of their instructors. The school in bad weather is held in apartments properly arranged for the purpose; but in fine weather the children are much out of doors, the air and sun may have the benefit of sufficient exercise in the open air. In this training school the children remain two or three years, according to their bodily strength and mental capacity. When they have attained so much strength and instruction as to enable them to unite without creating confusion with the youngest classes in the superior school, they are admitted into it; and in this school they are taught to read, write, account, and arithmetic, to sew; but the leading object in this more advanced stage of their instruction is to form their habits and dispositions. The children generally attend this superior day school till they are ten years old; and they are instructed to go at half-past four, and return for an hour or two every day during the whole of this latter period.'

In the year 1819 Henry Brougham, the Marquis of Lansdowne, Joseph Wilson, John Smith (who had seen the schools at New Lanark five years previously), Joseph Wilson, and other gentlemen, established, by subscription among themselves, a school in Brewer's Green (now Vincent Square), Tothill Fields, Westminster, on the plan of Mr. Owen's schools at New Lanark; and James Buchanan, an experienced teacher in New Lanark, was engaged, with Mr. Owen's approbation, to superintend the new school.

On the 24th of July, 1820, an infant school was opened in Quaker Street, Spitalfields, London. This school was established at the expense of Joseph and Sarah Owen, and was managed by Mr. Wilson. Samuel Wilderspin and his wife were engaged to manage the school, and their salaries were fixed and paid by Mr. Wilson. Mr. Wilderspin had been previously a clerk in a London bank, and engaged in mercantile business, and was in this situation for some years, and published a small work "On the Importance of educating the Infant Poor from the age of eighteen months to seven years, containing an account of the Spitalfields Infant School, and the new System of Instruction there adopted." By S. Wilderspin, master of the above school, 12mo., 2nd edition, with considerable additions, Lond., 1824.

The first edition was probably published in 1820, and it had no evidence. Mr. Wilderspin was afterwards employed in delivering lectures on infant education, in assisting in the establishment of new schools, and in otherwise promoting the cause of infant education in all parts of Great Britain as well as in London. Mr. Buchanan was master of the Westminster infant school about twenty years, and then went to America.

A pension of 100l. a year was granted (August 1848) to Mr. Wilson, and a pension of 200l. a year on the 3rd of August, 1848, in the House of Lords, made some remarks on Robert Owen's right to be considered the founder of infant schools, in which the Marquis of Lansdowne concurred, Mr. Wilson was also present. Robert Owen was called to answer August 6, 1846, (two letters, one to Lord Brougham and another to the Marquis of Lansdowne, in the former of which Mr. Wilderspin says—'With regard to Robert Owen and the system which Buchanan brought from New Lanark, your Lordship must be aware that the room at Brewer's Green was called an asylum, as was also the one afterwards established in Vincent Square, and that both contained a mere assemblage of children of all ages ranging from 18 months to 7 years, and at no time were disposed to be mere asylums as a refuge for destitute children, but not infant schools conducted on the system now called the infant school system. Buchanan did not become an infant teacher, nor did his school become an infant school until it had been re-organized by me, and he himself had instructed by me at the express desire of the committee. The system therefore which Buchanan taught was not Mr. Owen's, nor his own, but mine, of if therefore your Lordship means to state that Oberlin, Fellenberg, or Robert Owen, was the founder or inventor of the present infant school system, with its various arrangements, details, and implements, I must say that I never heard the Lordship's decision,' &c. Dated Bermondsey, August 6, 1846.

In the year 1824, Mr. Wilderspin, in the preface to the book mentioned, says, 'I do not know with whom the system of infant schools originated, but there is no doubt of its much importance to know this.' The first infant school that we heard of in this country was established at Westminster, in the year 1819. The master of that institution is J. Buchanan, who came from Mr. Owen's establishment at New Lanark. That Mr. Wilderspin made alterations, and also improvements in some respects, in the system, will be readily admitted; but from the evidence which has been quoted, it is obvious that the leading principles of infant education had been developed and the establishment of infant schools accomplished before Mr. Wilderspin was engaged in the management of the infant school system. The Church of England, in the "Journal of Education," vol. i., p. 359, &c. [Owen, P. C.] SCILENURUS, a genus of fishes fossill in the London clay. (Arms.)

SCILY. See Acanthopterygious ommous fishes, of which the genus Scilis is the type. They are closely allied to the perch, and resemble them in their general characters, but differ in having no teeth on the vomer and parasphenoid, and in the anal fin, which is armed with spines; the bones of the face and head are often cavernous, forming a protruding snout.

The "Scileniodes" are divided into those having two dorsal fins and such as have only one. In the first section we find
the genus Scionea, of which a single species, the maigre, Scionea aquila, occasionally wanders from the seas of Southern Europe into our own. Heaulme, Prisotonia, Diagramma, andamp; Apamphion are among the many genera belonging to the section of our subject.

SCINA; DOMENICO, born at Palermo in 1765, studied in his native town under Rosario Gregorio and other good masters, and became a proficient in classical erudition. He afterwards applied himself to the study of physical and mathematical sciences, and to the remainder of his life was chiefly devoted. In 1796 he was appointed Professor of Physics in the University of Palermo. He was repeatedly sent on journeys to the adjacent countries, and described the natural phenomena of the island, and he published the results of his observations. He gave an account of the eruption of Etna of 1811, in two letters: 1. Lettere scritte da Catania à Montignor Grano in Messina. He wrote on the currents of the straits of Messina: 'Memoria eti Fili Reifi, e i Vortici apparenti dello Stretto di Messina,' in which he gave a better explanation of them than either Spallanzani or Brocchi has done. In 1818 he published an interesting 'Topografia di Palermo et de' suoi Contorni; in which he describes the physical geography of the tract, its geological and mineral formation, its vegetable and animal productions, and its meteorological phenomena, and thus laid down the basis of the physical and meteorological map of the island. In the following year he was sent to explore the mountainous group called Monti Madonie, the ancient Nebrode, which rises in the centre of the island, especially with regard to the forests and agricultural productions. In 1820 he published 'Rapporto del Viaggio alla Madonie, istruzione per Ordine del Governo,' Palermo, 1819. In 1823 he went on a like mission to the district of Ogliastro, near Termini, where an earthquake had just occurred. The springs of the mineral waters from which the town of Termini takes its name. He wrote two reports on the subject, which were inserted in the Sicilian 'Giornale di Scienze, Lettere, ed Arti.' In 1817, a quantity of bone found in the same fossil remains found in the neighbourhood of Palermo, Scinco wrote a 'Rapporto sull'Ossa Fossilie di Mardolzo e degli altri Contorni di Palermo,' which excited much attention. When a voluntary collection of specimens of the sea-fossil was established, Scinco was sent to examine the new phenomenon, and he wrote a 'Breve Rappaglione del novello Vulcano.' Scinco was not neglected by the Sicilian government. Both King Ferdinando and his successor King Francis bestowed their favour upon him. In 1815 he was appointed historiographer of Sicily. In 1822 he was made chancellor of the university of Palermo, and a member of the commission of public instruction and education for the whole island. In 1823 he was made curator of the public library of Palermo, and also rector of the 'Educatario dello Nobili Donzelle,' or 'House of Education for young Ladies of Rank.' In 1839 King Francis presented him with a silver medal, and in the following year gave him the decoration of his own order, Scinco was also the author of the following works: 1. 'Introduzione alla Fisica Sperimentale,' 1806, a work which caused a great sensation, and in which the writer attempts to give a new view of the science of Physics. 2. 'Elogio di Francesco Maurolico,' a distinguished mathematician of Messina in the sixteenth century. 3. 'Memoria sulla Vita et Filosofia et Empedocle, Gentigento,' in 2 vols. 8vo., Palermo, 1815, a work more concise but not less accurate and interesting than that of F. W. Sturz, Leipzig, 1805, on the same subject. Scinco's book is divided into four parts; the first treats of the time in which Empedocles lived; the second is a biography of the Aggientine philosopher; the third treats of his philosophy; and the fourth is a collection of the fragments of his works translated and introduced into modern times. 4. 'Frommenti della Gastronomia d'Archeologia,' Palermo, 1823, with a biography of that ancient and little-known Sicilian poet. 5. 'Prospecto della Storia Letteraria di Sicilia.' The work contains an account of all the writers of any quantity of the pen in Sicily; the fruit mem-

SCIPIONE was a skilled archer, in reference to his proficiency into the art of archery. He is recorded to have been one of the most learned men that modern Sicily has produced.

(Tipaldo, Biografia degli Italiani Illustrati; Mortillaro, Sulla Vita et in Ens. ed Arte, Palermo, 1827. SCINK (Reptilia). [SCINCOIRAM, P. C.] SCIOPTIC BALL is a globe of wool about five inches diameter, with a cylindrical perforation 2 inches diameter passing centrally through it, and having at one extremity of the perforation a glass lens. The globe or ball is, by means of screws, fixed in a socket, which is made in a board about 8 or 10 inches square, in such a manner that while it cannot fall out, it is capable of being turned on its centre, to a small extent, in any direction.

The board being screwed to a window-shutter, or to the vertical face of a building in which an aperture has been made for the reception of the globe; the rays of light from external objects, after being reflected by the images of those objects on the opposite wall of the apartment, or on a white screen placed in a vertical position to receive the light; the apartment being darkened in order that the images may be distinct. The images on a vertical screen being inverted, two arms generally project from the board, within the room, and carry a plane mirror which turns on an axis so as to allow the rays of light, after passing through the lens, to fall on a screen placed in a horizontal position; by this means the spectators are enabled to see the images in erect positions. [CAMERA LUCIDA AND CAMERA ONSCIA, P. C.]

When the construction of the building is such as to allow the ball and lens to be fixed at an aperture in the roof, a plane mirror being placed above it at an angle of 45 degrees with the horizon, the rays of light can reflect the images of objects down on the lens, the images formed on a screen within the darkened apartment are more distinctly formed and more conveniently seen. An apparatus of this nature was formerly applied to the room in which the astronomical observatory at Greenwich, Edinburg, and Glasgow, for the amusement of visitors.

SICIRUS, a genus of plants belonging to the natural order Cyperaceae and the tribe Scirpeae; the stems uniform and equal glumes; the lower ones are perhaps the largest, and one or two of them empty. The bristles are either absent, or about six in number. The nut is plano convex or trigonous, and when wetted, or dipped in water, is of an oblong oval form.

S. maritimus has stalked or sessile spikes in a dense terminal cluster, several foliaceous bracts, bifold glumes, with an intermediate point; acute segments and a trigonous smooth nut. The stem is not only tending to the base, but erect, and the root is found in salt marshes in Great Britain, and is much relished by cattle. Withering says that the roots of this species are excellent, and have been ground down and used instead of flour in times of scarcity.

S. locustris, Bull., has a round stem from four to six feet high, naked, with one or two long sheaths at the base, the spikes in a terminal twice compound panicle; the glumes are emarginate, mucronate, glabrous, and fringed. The nut ob-

S. tuberosus is the tuberous or tubaceous, and when eaten is the principal food of the Chinese, and is cultivated by them for food in large tanks, which are regularly filled with water at intervals drawn off. The tubers are eaten both raw and cooked, and are consumed both as food and medicine. There are fourteen British species of Scirpus, none of which however are worth description on account of any quality of the panicle; the fruit membranous, one-seeded, indistinctly inclosed, included in the hardened calyx. The species are small herbs with opposite linear leaves which are rather coarse at the base. The flowers
are small, greenish white, and sessile in the axils of the forks of the branch.

S. annua, A. Fab., has subdecandrous flowers, segments of the calyx of the fruit, patent acute, with a very membranous margin as long as their tube. The styles are longer than the stamens, the stem green and repeatedly dichotomous. The flower green, often solitary. It is found
in the woods of Britain.

S. variegata, A. Fab., and Germanicum, A. Fab., inhale the vapour arising from a defection of this plant as a cure for the toothache.

S. perennis, with stellate flowers, the lobes of the calyx of the fruit closed, obtuse, with white and membranous edges. The styles are usually shorter than the stamens. The stem nearly simple, or irregularly branched, procumbent, and glandular. The flowers green and wide. It is found in sandy places in Europe, the Levant, and in England.

The Polish cockshel (Coccus Polonius) is frequently found on the roots and leaves of this plant in the summer months. The seeds of these plants only require to be sown in the open ground. None of the species are worth cultivating except in botanical collections.

SCROPHULARIA (from scrophulare, hard, and naked, grass), a genus of grasses belonging to the tribe Festucion. It has unequal acute membranous glumes. The outer pales with 5 faint but distinct and parallel nerves, membranous, cylindrical below, and keeled at the tip or with a very minute mucro. The styles are terminal.

S. maritima has a branched panicle, the lowest branches in pairs or simple, the branches alternately erect, the spikelets from 4 to 8 flowers, the rachis terete, the outer pales obtuse, apiculate, the midrib not reaching the apex, the root stoloniferous, fibrous, with rooting or ascending scions. It is found on sea-coasts and damp places in Great Britain.

S. distans is the Glyceria of Smith. It has a branched panicle, the branches elongated, ultimately spreading or deflected, the lowest in fours or fives, the spikelets linear, from 4 to 8 flowers, the rachis terete, the outer pales obtuse, with an apiculus formed by the extremity of the dorsal nerve; the root is fibrous; the flower large. It is found in salt marshes in Britain.

There are six British species of this genus.

SCLERODERMI, the second family of Plectognathous fishes (such as have incomplete and soldered jaws). The Scelodermi are distinguished by their conical or pyramidal snouts, ending in a small mouth, with distinct teeth in each jaw. The skin is rough, or covered with large hard scales.

The first division of Plectognathi is named Gymnonotidae. This group has no true mouth, but a substitute in a lamellated substance resembling ivory. Each fish covers the jaws. It includes the Tetradon, the Diastom, the Otagog, the isch, and other genera.

These are mostly tropical fishes, and are remarkable for their brilliant colours. One genus only occurs in the British seas, and that but very rarely; the Blaistes, or fish-like, is the one alluded to. The Ostracion is remarkable for having its body clothed in an inflexible armour of hard plates, the tail-fins, mouth, and gill-openings passing through holes in its coat of mail.

SCROPHULARIA, a genus of fish-bones belonging to the tribe Asplenaceae. The sori elongate, straight, and two together. The indusia of each pair opening towards each other. The leaves are convolute, is a generally handsome eel-like, ornamental form, and very different from every other British species. It is universally and abundantly distributed throughout the British isles. It is very commonly found on old walls and reposing in Europe and the North and in the United States. It is not however described as growing in Africa, Asia, or South America. The roots are black, stout, and very long and strong, the rhizomes fibrous, the leaves oblong, very young fronds make their appearance in April, growing in an erect position; by degrees they become horizontal, and at last pendulous. They arrive at maturity at the end of September, and continue in full vigour throughout the whole winter. The form of the frond is linear, elongated, and quite undivided, acute at the apex, and coriate at the base. This fern is the Pityrogramma of many and all botanists. It was once much in vogue as a medicine; it is mentioned as an astrigent to wounds and ulcers. Lighthouse says it is used by the people in Scotland as a vulnerary for burns and sores, and we learn from the Flores Franciae that it is used by the French as an astrigent in cases of diarrhoea and hemorrhage.

(Newman, British Firs; Babington, Manual of British Botany.)

SCORP. A. genus of Acanthophytogeous osseous fishes of the family Loricati. Their heads are large, compressed, or more or less armed with spines or tubercles; the body is slender, the head massive; the fins have all four rays; the branchiostegal membrane has seven rays; and the jaws and palatines are armed with velvety teeth. They reside mostly on rocky grounds, feeding on crustacea and small fish. One only inhabits our seas, and is very rare, the Beryl, or Norway haddock, a fish resembling the perch and attaining a length of two feet or more. In the Mediterranean are some beautifully-coloured species of this genus.

SCOTLAND, CHURCH OF. The constitution of this church has been considered under the heads of General Assembly, P.C., and Session, Kirk, P.C. An important portion of its history, throwing light on its present position, is narrated in the Irish Church. Of the Church of Scotland remains only chronologically to mention the chief events in the history of the church. The main struggles of the reformation in Scotland date at the middle of the sixteenth century. On the 31st of August, 1567, the Kirk of Scotland, at the head of the Romanish hierarchy, and on 20th December of the same year, the first general assembly was held in Edinburgh. In the ensuing year, the 'First Book of Discipline', still an important part of the ecclesiastical code of the established church, was drawn up. Various sects into which the Presbyterians of Scotland are now divided, was compiled. The fundamental principles of the reformed church were passed into an act of parliament in November, 1567 (2 Edw. VI.). The views of the Church of Scotland, the Faith and Doctrine believed and possessed by the Protestants of Scotland, exhibited to the Estates of the same parliament, and be their publick Votes authorized, as a Doctrine grounded on the infallible Word of God. This constitution however had more reference to doctrine than to church polity. It condemned some of the more prominent features of the system of the abjured hierarchy, but did not contain any announcement of the new system of church government. The early constitution of the church as approved by Knox and his friends, admitted of a difference of grades, certain clergymen being called 'Superintendents' of Provinces, which actually was a departure from the English bishops. The Presbyterian polity was at length established by the act of 1602 (c. 114), called 'Ratification of the Liberties of the trew Kirk of Scotland and certain Ceremonies of Discipline.' In the mean time those who had been the zealous clerical supporters of the reformation expected that the temporalities of the Roman Catholic church, at least, would be assigned to ecclesiastical purposes under the new system. They found however that the powerful laymen who assisted in the demolition of the old system had very different views. They spoke of this notion as a devot imagination,' and kept by far the larger portion of the spoil to themselves. After some hard struggles, in which the national feeling in favour of Presbyterianism was driven very nearly to an out- break, Episcopacy was re-established by the parliament of 1612. In 1637, the celebrated Liturgy, concocted by Laud and West, on principles nearer approaching to the Roman Catholic form than those of the English Liturgy, created the Church of England, or at least canonically established the Church of Scotland. On this occasion, great part of the assistance which the Covenanters received from the landed gentry was owing to their dread of a plan for restoring the church of England in the Scottish Kirk, the prevailing party in Scotland. Charles II., all the acts of the previous reign subsequent to the year 1625 were ' rescinded' or repealed, and consequently the Episcopal form of church government was restored. The system of church government in Scotland was not extended to the system on a people who abhorred it the more, the more stringently it was enforced on them by penal laws, is well known in history. These laws were relaxed, but not in a manner so as to give a just idea of the Church of Scotland, as James II, all to whom it was enforced by the established Episcopal
church. At the revolution the presbyterian form was re-established. The flowers of this plant are propagated, but prefer a moist situation. They are all readily propagated by seeds. The shrubby species require protection during the winter in a frame.

(Do. Gardener's Dictionary; Babington, Manual of British Botany; Burnett, Outlines of Botany.)

SCUTELLARIA (from the Latin 'Scutella', a 'little saucer', in reference to the form of the calyx; a genus of plants belonging to the natural order Labiatae. It has a capsule bilabiate calyx, the lips entire, the upper one with a concave scale on its back. The tube of the corolla, much exserted, 2-lipped, the viscid spur simple; the anthers of the two longer and inferior stamens 1-celled, of the shorter and superior one 2-celled. The leaves are opposite, simple, entire, and breve. The whole genus is remarkable for being provided with a cuneus, elongated support to its nut. This species was once considered efficacious in certain fevers. It is plentiful in Europe, Asia, and North America, in humid places, and in Britain.

S. minor, smaller Scutella, is a humble glabrous plant, with its leaves on short petioles, the lower ones broadly ovate, the middle ones ovate-lanceolate with the base cordate, the upper ones lanceolate, entire, acuminate. The corolla is white, variable and sometimes purplish; opposite, secured; the corolla almost glabrous, with the throat hardly dilated. It is native of Europe and Siberia, in damp places, and of Great Britain.

S. lateriflora has a slender stem, its leaves sessile, petiolate ovate lanceolate acuminate leaves rounded at the base; the upper floral leaves hardly exceeding the calyxes, the racemes axillary and terminal, the flowers opposite and secund. It is native of North America, on the margins of ponds, and was once extolled as a remedy for hydrophobia, but on no good grounds. Most of the species of Scutellaria are very pretty ornamental plants, and will grow in any common soil.

(Do. Gardener's Dictionary; Babington, Manual of British Botany; Lindley, Flora Medicinal.)

SCULLYODUS, a genus of fossil fishes. (Aguas.) From the chalk.

SCYPHIA, a fossil genus of Spongiae. Chiefly in the chalk. (Goldfuss.)

SEA-LIGHTS. Since the publication of the article Light-Houses, P. C., p. 478, some changes have been effected in the management of the coast-lights and beacons of the United Kingdom, and many important inventions for increasing the efficiency of sea-lights have been introduced. Our brief notice of these will be chiefly founded upon the First Report of the Select Committee of 1834 on the government of Light-Houses, in the session of 1834, and upon two papers on Recent Improvements in Light-Houses, published in the 'Penny Magazine' for 1842, pp. 286 and 294.

The Select Committee of 1834 had directed their attention chiefly to the alterations made in the lights and lighthouse establishments of the British Islands subsequently to the date of the Report of the Committee of 1834 (extracts from which are given under Light-Houses), report that by an act of 1836 (6 & 7 Will. 4, c. 79), all light-houses and sea-marks on the coasts of England were vested in the corporation of the Trinity House (Trinity House of Dedford, F. C., p. 245), which was empowered by the act to purchase the private light-houses of Harwich, Dunnegens, Winterton, Huxton, and Orford, which were held by individuals under leases from the crown; the Smalls and Longships, which were held on leases under the Trinity House itself; and the Skerries, Scarp, and Tynemouth lights, which were held by private parties in perpetuity under acts of parliament. The purchase of these ten lights was effected (the last in September, 1841), at an expense, by way of interest and payment for the interests of individuals, of 1,182,540l.; and the rights of the crown on the five first were surrendered on condition that the Possessions and Land Revenues of the Crown should be released from a debt of 300,000l. advanced out of the consolidated fund on their security. Thus, at a very large cost, the recommendation of the Select Committee of 1834 'to have all public lights placed under one board, and free from private claims' has, so far as the subject has been acted on, produced the desired effect, and, as the Committee of 1845 observe in their Report, parliament will thereby be enabled to legislate freely respecting them, in such manner as shall be considered best for the public interest.

Sea-lights are commonly divided into two principal classes,
of which the first, called in the Committee's Report Public General Lights, embraces such as are of use to all vessels passing the coasts; while the second, called Harbour or Local Lights, includes such as are intended specially for the use of vessels arriving at particular ports. The first class, or Public General Lights, are now, if in England, all under the management of the Trinity House; if in Scotland, under the Commissioners of Northern Lights; and if in Ireland, under the Ballast Board of Dublin. [BALLAST OFFICE CORPORATION, P. C., p. 330.] The second class, or Harbour or Local Lights, are 'managed, under powers given by the legislature, or emanating from other authorities, by corporations and local trustees, who collect the dues necessary for their support; but, under the act of 1836, the Trinity House has a general superintendence over those of England, their sanction being necessary to the establishment of new lights, and they giving directions as to the kind of light to be used, to avoid interference with the general coast lights. In Ireland, all the harbour lights, with the exception of one at Belfast, are managed by the Ballast Board, who receive the dues and pay the expenses of maintenance in the same way as for the public general lights.

From returns laid before the committee of 1845, it appears that the number of lights of all kinds has been greatly increased within a few years, as will be evident from the following details. The comparative number of lights of various kinds in England in 1834 and 1844 was as follows:

<table>
<thead>
<tr>
<th>Country</th>
<th>1834</th>
<th>1844</th>
</tr>
</thead>
<tbody>
<tr>
<td>Public General</td>
<td>57</td>
<td>141</td>
</tr>
<tr>
<td>Local or Harbour</td>
<td>51</td>
<td>54</td>
</tr>
<tr>
<td>Total</td>
<td>108</td>
<td>195</td>
</tr>
</tbody>
</table>

In Scotland (where, from the returns, all appear to be fixed lights), the numbers were:

<table>
<thead>
<tr>
<th>Country</th>
<th>1834</th>
<th>1844</th>
</tr>
</thead>
<tbody>
<tr>
<td>Public General</td>
<td>25</td>
<td>29</td>
</tr>
<tr>
<td>Local or Harbour</td>
<td>28</td>
<td>38</td>
</tr>
<tr>
<td>Total</td>
<td>53</td>
<td>67</td>
</tr>
</tbody>
</table>

In Ireland, at the same periods, the numbers were:

<table>
<thead>
<tr>
<th>Country</th>
<th>1834</th>
<th>1844</th>
</tr>
</thead>
<tbody>
<tr>
<td>Public General</td>
<td>28</td>
<td>36</td>
</tr>
<tr>
<td>Local or Harbour</td>
<td>14</td>
<td>30</td>
</tr>
<tr>
<td>Total</td>
<td>42</td>
<td>66</td>
</tr>
</tbody>
</table>

In which returns are included 5 local lights which, in 1834, were not under the management of the Ballast Board, and, in the second division, 1 such (at Belfast) which was still, in 1844, out of their jurisdiction.

The aggregate statement, without distinguishing floating from fixed lights, stands thus for the two periods:

<table>
<thead>
<tr>
<th>Country</th>
<th>1834</th>
<th>1844</th>
</tr>
</thead>
<tbody>
<tr>
<td>England</td>
<td>71</td>
<td>126</td>
</tr>
<tr>
<td>Scotland</td>
<td>35</td>

</tr>
<tr>
<td>Ireland</td>
<td>20</td>
<td>46</td>
</tr>
<tr>
<td>Total</td>
<td>126</td>
<td>227</td>
</tr>
</tbody>
</table>

showing an increase in little more than ten years (for the returns dated 1834 refer, at least in some cases, to 1833; while those given under 1844 appear to be actually for that year), of 85 lights, classified as follows:

<table>
<thead>
<tr>
<th>Country</th>
<th>1834</th>
<th>1844</th>
</tr>
</thead>
<tbody>
<tr>
<td>Public General</td>
<td>20</td>

<td>Total</td>
<td>30</td>
<td>60</td>
</tr>
</tbody>
</table>

In addition to the above there were, in 1844, 7 local lights belonging to the Isle of Man, which, having been included in the returns for 1834, we have omitted in those for 1844. These raise the number of local lights for the United Kingdom 159, and the gross number 690.

Of the 94 fixed general lights in England and Scotland 76 were, in 1844, autoptic lights, with an aggregate number of 1008 burners, which gives an average of nearly 14 burners to each light, and 18 were electric, of power equal or aggregate of 258 burners, which gives an average power of 14 burners to each light. The aggregate illuminating power of the fixed general lights in England and Scotland, therefore, equal to 1562 burners, while that of the 25 English floating general lights (exclusive of that at Plymouth breakwater) was 288 burners, giving an average power of 1 ½ burners to each light. In Ireland the fixed lights had an aggregate power of 583 burners, which gives an average of rather more than 21 ½ per light, and the 29 harbour lights under the Ballast Board an aggregate of 216 burners, which gives an average of rather less than 7 ½ per light.

From the evidence laid before the committee of 1845 it would appear that the public general lights of the United Kingdom are in an efficient state, and, according to a witness who had ample opportunities of comparison, on the whole superior to those of the United States of America: while no complaints were made of their want of brilliancy or general efficiency, many were laid before the committee, both by petitioners and sworn witnesses, of the high charge for light dues, the mode of levying them, or the irregularity of their rates. How greatly the gross amount levied upon commerce in the shape of light dues has increased since the date of the Report of 1834 will be seen from the following comparative statement of dues levied in each division of the United Kingdom in 1834 and 1843. The return for England and Scotland appears to apply solely to general coast lights, no complete account being given of the dues from harbour lights; but that for Ireland embraces such, they being, as before stated, in the hands of the Ballast Board. Of the dues levied in England in 1832, only 83,041£, belonged to the Trinity House; private individuals, however, in 1843 the whole fell into the hands of the Trinity House.

The figures are from the statements laid before the committee of 1845, and it appears that these charges, which, in consequence of the general increase of shipping, are more oppressive to trade, are not only far higher than necessary for the mere maintenance of the lights, but are also levied with a more peculiar air of preposterousness, imposed upon particular branches of the shipping interest. Steam-packet companies especially complain of the amount of the dues as compared with the advantages derived. The Peninsular and Oriental, and the Steam-packet Company state that four of their vessels employed on the Peninsular line, of an average tonnage of 368 tons, and making fifty-two voyages in the year 1844, paid 122 7s. 4d. per voyage for light dues, or 845£, 1s. 4d. in the course of the year; and that two others, plying between Southampton and Alexandria, averaging 888 tons each, and making twelve voyages in the year, paid 28£, 14s. per voyage, or 356£, 8s. per annum. One case that appears of peculiar hardship is that of a partner in a trading between Granton, in the Firth of Forth, and Dundee, completing its voyages entirely by daylight, and therefore deriving no benefit whatever from the lights; but, which, nevertheless, paid during the following amount in light dues, which it was at work for forty-nine weeks, and three weeks refraining:

- Thirteen weeks of double voyages, at 16£, 13s. 9d. per week. Total 212 £, 18s.
- Thirty-six weeks of single voyages, at 10£, 10s. per week. Total 489£, 6s.

For total forty-nine weeks . 702£, 4s.

On the coasting trade also the light dues are found very burdensome, especially where the competition of railways is felt. One vessel employed in the coal-trade, of which particulars were laid before the committee, made in the years
SEA

1843 and 1844 thirteen voyages, with an average load of 400 tons, carrying goods for the British market, and the cost of 6½. 10s. 7d. or more than 32 per cent. had to be paid for light dues; and Mr. Ogilvy, a London shipbroker of forty years' standing, stated in evidence that the traders to the principal ports in the British dominions should have part on 5s. 8d. per ton on the average of the year; that vessels from the Mediterranean and the South of Europe, making a less number of voyages, pay 3s. 6d. per ton; and ships to India and China, making one voyage in the year, 11s. 8d. per ton; and that the coasting trade, now in the present state of competition, would consequently benefit the most by the abolition of the light dues. The following table, compiled from the returns given in the Committee's Report, shows what proportion of the light dues of each division of the United Kingdom is derived from each class of ships.

The light-dues are, it should be observed, charged upon the whole tonnage of a vessel, however small may be the crew, and are charged on the ground of the tonnage of the ship, whether one ton, or one box, or one passenger paying freight be on board from port to port, light-dues for the whole ship's tonnage is invariably charged; and consequently the ships often are loaded with a smaller quantity of cargo; a course of proceeding which, in the coast-trade of Ireland, operates very injuriously on the merchants, and on the consumers in the smaller ports to which the vessels go.

Of the recommendations of the Committee of 1845 for removing the evils complained of we need say very little, especially as nothing has, down to the close of the session of 1846, been done to give them legislative effect. Their principal features are the proposed transfer of the management of all public lights, buoys, and beacons, on the coasts of England, Ireland, and Scotland, to one central board, which it is suggested should be the Corporation of the Trinity House, with some modifications in its constitution; the defraying by government of the heavy debt incurred by the Trinity House in building up private lights; and the future maintenance of public lights, buoys, and beacons either out of the public revenues of the country, or by a small toll-rate on all the registered tonnage of the United Kingdom, and all colonial and foreign vessels entering its ports: such rate being made out of a large surplus revenue for pensions and charitable purposes. They suggest that it may deserve to be considered whether the ships of the Navy, and those in the Coasting Trade, should be put upon the same footing, as, as they now are, exempted from the payment of light-dues; and they conceive that a more economical mode of collection, by the agency of the officers of Customs, might be suggested by the general government.

One interesting detail of the investigations of the late parliamentary Committee is that relating to the cost of various modes of illumination. Their Report states that for many years past the French have used colza or rape-seed, which costs about 3s. 8d. per gallon, while the best sperm oil, which is usually burnt in English light-houses, costs from 6s. to 8s. per gallon. It is admitted that a greater quantity of colza than of sperm oil is necessary to produce the same effect, yet some of the witnesses examined expressed an opinion that one-half of the expense of the oil consumed might be saved by its use, and how seriously any such saving would affect the general cost of maintaining light-houses may be perceived from the statement that, out of 701l., the total expense of the Flamborough light in 1843, 302l. was expended on oil, and that in the Dungeness light-house the same item amounted to 225l. in a total expenditure of 639l. Mr. Alexander Gordon, however, in his evidence, objects to rape-seed oil because, in common with all other vegetable oils, it wastes by burning to over-flow, and occasions increased labour in trimming the lamps. He suggests that, in the case of small lights, it might be advisable to use rape-seed oil for the illumination of the lantern, and that the lights should be supported by the general government, there were, on the 1st of July, 1842, 243 fixed and 30 floating lights, having an aggregate power of 2671 burners.

In advertising these and the more important mechanical improvements recently introduced in the construction of light-houses, we may, first notice the construction of such buildings wholly of iron or other metal. Though first carried into effect by Mr. Alexander Gordon, this improvement would appear, from the first of the papers already referred to in the 'Fenny Magazine,' to have been previously suggested by the ingenious Captain (afterwards Sir) Samuel Brown, who is best known for his share in the introduction of suspension-bridges and piers, and who proposed to erect a light-house of either iron or bronze upon the Wolf Rock, near the Land's End. His plan was to construct a tower 20 feet high, 14 feet in diameter at the bottom, and 8 at the thinnest part, composed of several truncated conical pieces of cast metal, fitting one another like the joints of a telescope. Within the body of this metallic column were to be sleeping-bettas for the attendants, and store-rooms for provisions, fuel, water, and oil; and at the top was to be the keeper's house, surrounded by an open hanging-gallery, and surmounted by the lantern. Captain Brown's conception would pose would point the advantages of being much less costly than a stone light-house; of requiring much less time for its erection; of presenting a much narrower surface for the sea to act against; and of greater security and stability. In 1842 it was intended to have but eight joints from the ground to the lantern, while a stone structure would have many thousands, and that, the whole circumference of each stage or story being cast in one piece, it would be capable of resisting enormous pressure.

Captain Brown's simple and ingenious design was not carried out.

---

*The discrepancy of 172 between these sums and those in a preceding table arise, in part, from the omission of fractions. The items given above are as in the Report.*

SEA

530

is effect, but a cast-iron lighthouse on a somewhat different plan was erected in 1842, by Mr. Alexander Gordon, upon an unhealthy lagoon in Jamaica, where, owing to local difficulties, it was composed of a tower of marble, and about 1846 four or five such towers had been constructed for less than 20,000L., or in a less period than six years, with the almost inevitable loss of many lives. For this locality Mr. Gordon designed an iron tower, a model of which was exhibited at the great Exhibition of 1851, and it looked so promising that it was purchased by the Commissioners of Ireland. The erection was determined on by the commissioners in Jamaica on the 8th of March, 1841; some months after, the first was ready for about 120L.; and it was ready for lighting early in August, 1842, though not actually lighted until November. The cost of the tower and lantern, including the fitting up in London, taking to pieces, packing, and shipping it in destination, was 1,300L., and the putting up (exclusive of the excavation of the coral rock upon which it stands) cost about 600L. Additional. The diameter of the tower is 18 feet 6 inches at the base, and diminishes regularly to 11 feet at the top; and instead of being formed, as in Captain Brown's plan, of a few large castings, each embracing the whole circumference, it is formed of nine tiers of cast-iron plates, each 10 feet high, from 4 feet to 5 feet wide, and 4 inches thick, the circumference being composed of eleven such plates at the base of the tower, and nine at the top. These are cast with flanges all round their inner edges, and, when put together, these flanges form the joints, which are secured with flat nuts and washers, and caulked with iron cement. The cap or top of the column consists of ten radiating plates, which form the floor of the light-room, these being secured to the tower upon twenty pierced brackets, and an iron ring above by an iron cap. The lantern is also of iron, glazed with plate glass, and it is supplied with a revolving light, consisting of fifteen Argand lamps and reflectors, five in each side of an equilateral triangle; so arranged as to produce a continuous light, but with periodical flashes. The tower rests upon a coral rock, upon which is laid a grooved course of granite to receive the flange of the lower plates, from which lightning conductors extend into the sea. The base is covered with granite, to protect the iron from the action of such sea-water as might filter through the stratum of sand which covers the coral rock; and the protection is increased by coating the exterior of the iron with tar. The interior of the tower, to about one-fourth of its height, is filled up with masonry and concrete so as to form a solid core, which imparts great stability to the structure; and above this are the necessary rooms. Of the precise nature of the arrangements actually adopted for securing comfort in this singular habitation we are not informed, but it is stated in the 'Penny Magazine,' on the authority of a paper in the 'Civil Engineer's Journal,' published while the structure was yet in progress, "to preserve the internal temperature and the air currents and climate will permit, the iron shaft or tower is to be lined with a non-conducting material, such as slate or wood, leaving an interspace through which a constant vertical current of air is to be directed, so as to prevent the deposition of moisture and heat." In his evidence before the parliamentary committee of 1845 Mr. Gordon stated that a taller and better lighthouse of similar construction was in progress for Bermuda, which would be about 150 tons, and would contain in its base about 450 tons of masonry and concrete. Among the numerous advantages of this kind of lighthouse may be mentioned their superior safety in thunder-storms; the whole structure constituting a great unbroken conductor for the lightning; and the safety arising from the whole being virtually in a single piece, and therefore far better able than a tower of masonry to resist the shocks of earthquakes, to which, as well as to violent thunder, the Jamaican lighthouses have been repeatedly exposed. The iron-work is so constructed as to be readily put together from inside, without any external scaffolding; and these, in common with other iron lighthouses and beacons, have the convenient property of being easily removable, in case the shifting of sands or any other circumstance should render a change of position desirable; a contingency, which, as will be seen by reference to Sutherland, P.C., p. 206, has already occurred, and which is very likely to recur as the substitution of fixed for floating lights in the vicinity of shifting sands, and the application of harbour lights.

A somewhat similar construction of lighthouse was proposed in 1836 to a Select Committee of the House of Commons on Shipwrecks, by Mr. Bush, as suitable for erection on the coasts of New South Wales, where the extreme difficulties of the locality have hitherto deterred the Trinity House from establishing any other than a floating light or light-ship. Mr. Bush's plan, as then proposed, was to construct, on land, a wooden truncated cone 100 feet high, fixed in base at the top, and 90 feet at the base, and protected by a circular base cone which should be in contact with it at the base, but, diminishing less rapidly as it rose, should gradually recede from it towards the upper part and be cut off at an angle forming a cone, and so anchored by means of bolts into the soundings of the sea. Below this was to be filled with sand or other heavy materials after the structure was floated to the required position, so as to sink it in the sea until it found a firm bottom. The sand included in the cone was to be drawn out, leaving the double cone as a kind of cofferdam, and its place supplied with a solid mass of masonry or concrete, which might form a secure foundation for an iron lighthouse. The large window in the upper part would be covered with iron sheets without endangering the structure. Since 1836 Mr. Bush has, at his own expense, partially carried out his scheme in a modified form, using a cylindrical caisson of iron 64 feet high and 30 feet in diameter in lieu of the proposed timber cone; but it appears by the evidence laid before the Lighthouse Committee of 1845, that the Trinity House refused to sanction the lighting of his unfinished structure, and that some of its officers deemed Bush's plan to be impracticable. Mr. Bush proposed not merely a lighthouse, but an extensive asylum for shipwrecked sailors, and even the construction of a harbour of refuge at the Goodwin Sands. In connection with this plan Mr. Bush drew attention to the high cost of building in iron as compared with timber, and to the limits of our subject, the experimental safety-beacon erected in 1840 upon one part of the same dangerous sands by Captain Bullock. This beacon, which is intended to mark the space between a numbered chain and a beacon near or even as a beacon of direction, consists of a strong mast or spar about 40 feet high, surmounted by a flag-staff 10 feet high, and supporting, near its upper extremity, a gallery 9 feet in diameter and 15 feet 6 inches in height, principally of sail-cloth, capable of holding forty persons, to which access may be obtained from below by means of ropes and ladders or notches in the mast. The mast or shaft is secured to a massive platform or cap of oak, surmounted by a cap of iron, and is loaded with upwards of three tons of iron ballast; and it is further supported by oblique bars of iron and chains. The mainmast or shaft of the beacon stands about 60 feet above the dry sand at low water, and 17 feet 6 inches above high water at spring tides. In the gallery is placed a barrel of fresh water and a bag containing a blue flag, which is to be hoisted when assistance is required from the land, which is seven miles distant; and to render the beacon accessible to all who are likely to make use of it, directions to 'hoist the flag' are painted in eight different languages on the sides of the gallery.

Perhaps the most curious recent invention connected with our subject is that of Mr. Alexander Mitchell, of Belfast, for constructing lighthouses and beacons entirely supported by piles, which, instead of being driven into the ground like those usually employed, are supported by ordinary mooring screw or mooring posts, each provided with a screw attached to their lower extremities. These screws, which were first employed instead of mooring-anchors, are of cast-iron, and consist of a broad thin plate or share wound round, the upper end being cast in the form of a screw, and the diameter of the screw being from two to five feet, and the thread or share taking only one turn and a half round its axis, and having its outer edge sharp, so as to cut its way readily, and when the axis is turned round by suitable means, into sand or earth, while its broad surface offers great resistance to any attempt to pull it out of its place. The great success of this invention, as applied to moorings, led to the attempt to apply it to the erection of lighthouses upon sands, for which purpose it bade fair to become highly important, as such lighthouses may be erected where there is not sufficient depth of water to moor a light-ship, and fixed lights are always more secure and less expensive to maintain than floating lights.

The first screw-pile lighthouse was commenced on the Maple sands, at the mouth of the Thames, in 1838, by screwing into the sands eight wrought-iron shafts, arranged so as to form an octagon of about 40 feet diameter, with a slight inclination inward towards the upper extremities, and a ninth perfectly upright, in the centre. These shafts were about 28 feet long, 21 inches in diameter, and to their upper ends were secured a series of cast-iron pillars, strongly braced and bound together, supporting a massive timber framework upon which is built the lighthouse, comprising store-rooms and apartments for the keepers. This lighthouse was not completed until February, 1841, but in
November, 1839, a similar structure, supported upon seven instead of nine piles, was commenced at the mouth of the river Medway. It was designed to form the new port of Fleetwood, which was completed in June, 1840, at a cost of about 3500£. In both these structures the supporting framework is left open to a considerable extent, and large, smooth surfaces of water are exposed to the action of the waves, which are reflected back with such force that they serve to keep the shores clear. The works in question are not new establishments, but are intended to be made to accommodate the traffic of large ships, and the object is to prevent the formation of a beach. The works are constructed of timber, and are supported by steel arches. The whole is to be completed in two years, and the cost is estimated at 1200£. The structure is to be made of iron, and is to be constructed in such a manner as to be capable of being raised or lowered at will. The works are to be carried on by the company, and the cost is to be met by the Government.

**SEAMEN.**

_Employment, Wages, &c., of Merchant Seamen._—The 5 & 6 Wm. IV. c. 19 repealed all former acts which regulated the wages of seamen. The 5 & 6 Wm. IV. c. 19 has been repealed, (except so far as such act repeals the acts thereby repealed, and except so far as relates to the establishment, maintenance, and regulations of the office called 'The General Register Office of Merchant Seamen'), by the 7 & 8 Vict. c. 112, which contains the present law relating to merchant-seamen and for keeping a Register of them. This act contains sixty-four sections: s. 6, &c. regulate the agreement of hiring seamen; s. 6, &c. assign the punishment of seamen for refusing to join the ship, or absenting themselves from it; s. 9 fixes the forfeiture for desertion; s. 11 the periods within which wages must be paid; s. 13 the payment of wages; s. 14 the payment of wages not exceeding twenty pounds; s. 17 provides for seamen being sent home when the ship is sold in a foreign port; s. 18 regulates the supply of medicines, lime or lemon juice, and other provisions. The act also contains a schedule of the words and phrases used in the act, and a schedule of the words and phrases used in the act.

The second of the two papers above referred to in the _Penny Magazine_ contains a notice of an important suggestion made by Captain Basil Hall in a letter to the _Herald of Service_, in reference to revolving lights. A fixed light, if required to be seen in one direction only, may be readily mounted with a parabolic reflector, so as to show at a very great distance; but where the light is required to be seen in all directions a difficulty arises, because, even supposing twenty-four distinct lamps, each having its own reflector, to be arranged in a circle, they will, owing to the light being reflected by the parabolic surfaces, be seen in all parts of the horizon, leaving the intervening portions in darkness, while at the same time the light will, from being so divided and scattered, be less efficient than if it were concentrated undivided by the parabolas. The greatest advantages of revolving lights, for instance, as the case is put by Captain Hall, instead of twenty-four lamps arranged at equidistant intervals round the circle, six are directed by their reflectors, due north, due south, due east, and due west, and that part of the lighthouse upon which the four sets of lamps are mounted be caused to revolve upon a vertical axis, the four concentrated blazes of light, instead of illuminating only the four points to which they were originally directed, will light up, in succession, every part of the horizon, and that with a blaze of light six times more powerful than in the case first described. As, however, variety is essential to prevent one light becoming wearisome to another, it frequently happens that a fixed light must be adopted for the sake of distinction, notwithstanding its inferiority. Captain Hall suggests, therefore, that a revolving light should be made to rotate on its axis with such rapidity as to exhibit an unbroken line of light along its path, on the principle of a burning stick whirled round so as to produce the appearance of a circle of fire. By this means, light would, with the superior brilliancy of the revolving light, be continuous in every direction.

An important improvement has recently been introduced by Professor Kirwan, a method of producing a revolving light, upon which paper was read before the Institute of Civil Engineers on the 27th of June, 1843. The want of proper ventilation in ordinary lanterns occasions the production, by the combustion of the oil, of water and carbonic acid. The water condenses upon the glass windows and dims them, while the carbonic acid often renders the air in the lantern so irrespirable as to render it very difficult for the keepers to attend to the navigation of the vessel. Owing to the exposure of lighthouses generally, ordinary means of ventilation, by allowing the free admission and egress of air, are inapplicable; but Mr. Kirwan, having his attention directed to the subject by the late John Hogg, has proposed a contrivance which has answered well, and which does not endanger the lights by permitting gusts of wind to get into the bowl. The contrivance is very fully described in an abstract of the paper referred to, in _The Athenæum_ 1844, p. 697.

**SEA-NETTLE.** [Actinia, P. C.]

**SEAMEN.**
on shore, to the sea-service, to be employed as is provided in the case of apprentices to the sea-service under s. 32, for the period then remaining unexpired of their apprenticeship. Several persons present, including the Lieutenant of the eighty tons and upwards, except pleasure-yachts, shall have apprentices in proportion to their tonnage, as in this section provided; all which apprentices must at the time of being bound be under the age of twenty-five years, and have completed ten years of age, and be duly bound for four years at least. Section 50 provides, 'That nothing in this Act, or in any agreement contained, shall prevent any seaman or person believing himself to be deserting, or taking any vessel, what it may have been entered into the naval service of her majesty, nor shall any such entry be deemed a desertion from the ship or vessel, nor shall such seaman or other person thereby incur any penalty, to be either of wages, clothes, or effects, or other matter or thing.'

The commerce of Great Britain gives regular employment to a vast body of seamen, and the habits and occupation of a large number of people on the sea-coast give them a relish and a capacity for sea-service. With the great increase of the commercial navy of Great Britain which has taken place of late years, and the prospect of still greater increase of commerce by the restrictions on trade being removed, we may always reckon on a sufficient number of seamen in the commercial navy to make up the deficiency in the royal navy in case of a sudden war. The apprenticeship system also is well devised to keep up a regular supply of young seamen. It is probable that ten or twenty thousand men might be at once drawn from the commercial navy for the royal navy on any sudden alarm, although among them better men might be prevented from being imported. The amount of inconvenience that may be sustained by the merchant-service by the withdrawal of a great number of seamen at once, is the same, whether the seamen are impressed or go as volunteers; but to the inconvenience arising from the actual withdrawal of seamen by impressment must be added the loss and inconvenience to the merchant-service which may arise from seamen keeping out of the way in order to avoid being impressed.

SEDITION (from the Latin sedition). It is stated that in many of the old English common law writers treason is sometimes expressed by the term Sedition; and that when law proceedings were in Latin, sedition was the technical word used in indictments for treason, till it was superseded by the word pro ditio. Sedition does not appear to be very exactly defined. It is stated to comprehend contumacious, indecent, or malicious observations upon the king or his government, whether made in words only, or in writing, or by tokens (which last term must be understood), and of acts committed looking to or bringing him in the opinion of the subjects or to weaken his government. All those offences fall short of treason; but they are considered crimes at common law, and punishable by fine and imprisonment.

There are also statutes against particular acts of sedition, such as seditious libels. [Law, Criminal, P. C. S., p. 176, No. 40.] There are also various acts against societies established for treasonable purposes, and against sedition meetings and assemblies.

The Roman sense of Seditio (sed or se, and i6, a going apart, a separation) is properly a disunion among the citizens, a riot, or turbulent assemblage of people for the purpose of accomplishing some object by violence or causing fear. It was included among other forbidden acts in the Lex Julia de Majestate. (Dig. 48, tit. 4.) It is often used in connection with 'delinquent' and 'turbulent,' and the three terms seem to have the same signification. (Rein, Römisches Criminalrecht, p. 262.)

SELM II. The son of Sultan Mustapha III. was born Dec. 1764. Mustapha III. was succeeded by his only brother Abdul-hamid, and Selim was shut up in the seraglio among the women and eunuchs. Abdul-hamid died April 7, 1768, and Selim then became sultan. The principal events of his reign are the following: He married a Turk, Turks, P. C., p. 404. He was deposed May 29, 1807, and Mustapha IV., son of Abdul-hamid, was elected in his place. Selim was put on government, and was strangled by order of Mustapha, July 28, 1808. Mustapha was deposed, and immediately the sons of Selim was set up, and was succeeded by Mahmod II. (Mahmud II., P. C. S., Mustapha IV., P. C.)

SELVA, GIANNANTONIO, was born of respectable parents, at Venice, June 15, 1758, and had for his earliest instructor his uncle the Abbate Giannantonio Selva, a man of considerable literary and scientific attainments. His inclination leading him to make choice of art as a profession, he was placed in the studio of Novelli (a painter who died in 1804, aged 75); but after he had ground himself in drawing and the elements of painting, he passed to the study of architecture, and became a pupil of Canova, with whom he visited Naples, Pompей, Caserta and Pozzúm. While at Rome, he also obtained the notice and favour of his countryman the nobleman Giuseppe Zulian, who also was then the ambassador from the republic, and who was a liberal encourager of art. By him Selva was commissioned to emboss and fit up a salon in his palace expressly for an entertainment given to the Ambuscardi Ferdinando of Austria and his bride; before which he had been similarly employed by the Senator Reszonzio to decorate an apartment for him, which was to have been done by Canova, but that architect was then obliged to depart for Ferrara. [Trezanoni, P. C.] On quitting Rome Selva visited France and England, in both which countries he diligently collected information of every kind bearing upon architecture and building; and returned to Italy much improved. He had, moreover, been offered, he introduced various practical improvements, and among them greater attention to internal convenience and disposition of plan, setting also the example of a more sober and simple style of building. As soon as he was engaged in his first important work, the Theatre della Fenice, his design for which was selected from among those sent in by twenty-nine other architects [Theatre, Hebe, P. C.]. Another structure of the same class designed by him was the theatre at Trieste, but in the execution of the work very great liberties were taken. A third theatre planned by him was never executed, but when he was some years afterwards at Florence, he found that parts of his design had been adopted for the theatre then lately erected there. To the above may be added the façade of the Casa Vigo d'Arzeri, and a Casino at Padua; the Casa Vela at Verona; the façade of the church Spirito Santo at Udine; the façade of San Maurizio at Bergamo; the façade of the Casa di Carpani, after whose death it was completed with some modifications by Diedo. The same fate attended his last and most favourite work, the small church Del Gesù, which was finished not long after his death. (Archive of Venice, 1781.) For the work of Venice his designs (author of important works and descriptions in Cicogna's ' Fabbriche piú consigli di Venezia,') and Giuseppe Borso. Selva died rather unexpectedly, at the beginning of 1819, and therefore could not have carried out his last work. (Triglè says he died at Possagno, the first stone of which was not laid till July 11th in that year. Two years before, indeed, he made a journey to Rome expressly to visit his friend the illustrious sculptor, and he may probably have then given the latter some hints and ideas, but beyond that he certainly had no share in the structure. Selva was also a writer upon subjects of his art; he as well as Diedo contributed to Cicogna's work above mentioned; and also to Formigli's treatise on the orders, and Chambers' 'Civil Architecture.' There is a portrait and short notice of Selva in Gamba's 'Galleria de' Litterati.'

SEMI NOTUS, a fossil fish from the lapis. (Agassiz.)

SEMITIC LANGUAGES. [Araba, P. C., p. 218; Aaram, or Aaramic Language, P. C.; Hebrew Language, P. C.; Sabrze (in honour of John de Senebiel, of Geneva, a vegetable physiologist), a genus of plants belonging to the natural order Cruciferae. The flower is somewhat kidney-shaped, entire at the end, or notched above and below, and almost 5-lobed. It is immediately followed by the calyx and the calyx stands a sepal one seeded. S. cornicopus, common wart-cress, has an undivided uniform crest; with some sharp aliers, the pouched in dense clusters. The leaves pinnate lobed. The stem much branched and prostrate. The sepals roundish, with white.
mambruous margins. This plant was formerly gathered and eaten as a salad, but it has since been reasonably neglected, as it is acrid and unpleasant, and must require much boiling to render it edible. It is native of Europe, North America, and Central and South America.

S. didyma, has a pouchouchted by two wrinkled lobes, an extremely short style, and pinnatifid leaves. The stem is spreading, about a foot in length. The flowers small and white, and the calyx 3-cleft. It is found on waste ground near the sea in Great Britain.

S. nilotica is eaten as a salad in Egypt. As these plants possess no beauty, they are not worth cultivating except in botanic gardens.

(Don, Gardner's Dictionary: Babington, Manual of British Botany.)

6. SEPARATION. [JUDGMENT, P. C. S.]

SEPARATION. [Wright, P. C.]

SEP'TA'RIA, a genus of acanthus mollusks, belonging to the family Tubicidae, in the arrangement of Lamarck, who defined the shell thus:—Tube testacea, very long, gently attenuated posteriorly and divided internally by arches, in complete partitions. Anterior extremity terminated by two slender tubes, which are not chambered in the interior. The Septaria arenacea is the type. It is the same shell described and figured by Dr. M'Intosh of India, a transliteration of two of his Travels into Africa, under the name of Teredo gigantea. It lives in sand in the Indian seas. A second species, unknown to Lamarck, lives in the Mediterranean, and has been described by Dr. M'Intosh in a letter written to Dr. Barnaby, and similar to that of Teredo. M. Deshayes considers the two genera identical, and his opinion will probably be hereafter adopted by most naturalists.

SEQUESTRATION. [Benspice, P. C. p. 281.]

SEQUESTRATION (Scotland). [Bankruptcy, P. C. S.]

SERAMPORE MISSION. A brief account of the origin of the Baptist Missionary Society, and of the history of this case, one of the most prominent events of the last year, having been given under Missions, P. C. p. 237, an article under this head is chiefly required to supply the omission in its proper place of a memoir of William Carey, D.D., its principal founder and leader.
